CUK-H06676-151-RP281

NATURE

A WEEKLY JOURNAL OF SCIENCE

> "To the solid ground
> Of nature trusts the Mind that builds for aye"—WORDSWORTH

University College of Science,
PHYSICS Dept.
Upper Circular Rd, Calcutta.

151

Volume 151

JANUARY 2, 1943, to JUNE 26, 1943

LONDON
MACMILLAN AND CO., LTD.
NEW YORK: THE MACMILLAN COMPANY

RP R282

INDEX

NAME INDEX

Prof. Rudolf: *Death* of, 49; *obituary*, 217
m, E. P., Chain, E., Baker, W., and Robinson, Sir Robert: Penicillamine, a Characteristic Degradation Product of Penicillin, 107
nia Nacional de Medicina of Buenos Aires: Establishment of the Hirsch Medical Scholarship Fund, 557
ny of Sciences of the U.S.S.R., and the Soviet Scientists' Anti-Fascist Committee: Message of greeting read at the Conference on Planning f Science in War and in Peace held by the Association of Scientific Workers, 153
Prof. F. D.: *Death* of, 49; *obituary* by Prof. C. E. Tilley, 102
J., and Snyder, L. H.: Inheritance of Infantile Paralysis, 477
utical Research Committee: Sir Bennett Melvill Jones appointed chairman, 331
the War and Peace Aims, Committee on: Supplement to the Atlantic Charter and Africa from an American Standpoint (Rev. Dr. E. W. Smith), 418
ultural Bacteriologists, Society of: Annual Conference, 172
ultural Education Association: Annual Conference of, 114, 143
ltural Research Council: Report on Agricultural Research in Great Britain, 396
ture and Fisheries, Ministry of: Scholarships for courses in an agricultural subject, in veterinary science, and in agriculture, horticulture, or dairying, 389
d, I. A. R. S. (Koller, P. C., and): [illegible] of X-Rays on *Drosophila pseudo-obscura*, 56
nder, Dr. A. E.: Modern Views on Emulsions, *review*, 542
Dr. Edgar: *Death* of, 471
Dr. E. J.: *Obituary* by Dr. W. R. G. Atkins, 48
Prof. F. J.: *Obituary* by Prof. H. Gilding, 132
Prof. H. S.: Nature of Entropy, 225
one, Dr. T. E.: Mechanism of the Electric Spark, *review*, 178
t, A. C.: Birds of the British List wintering in West Africa, 20
ion Society for Cultural Relations with Foreign Countries (Medical Section): Scientific bonds of Soviet medical circles with medical and scientific workers in other countries, 444
G. B., and Tetlow, N.: Application of Electricity in Mine Pumping, 79
can Association for the Advancement of Science: Retiring Presidential Address by Dr. Irving Langmuir on Science, Common Sense and Decency, 266
Isaiah Bowman elected president, 639
ican Association of Petroleum Geologists: Memorandum to Members of the National Service Committee (F. L. Aurin), 119
can Association of Scientific Workers (Rockefeller Institute for Medical Research and the): Greetings exchanged with the Association of Scientific Workers at the Conference on Planning in War and in Peace, 154
can Chemical Society (Chicago Section): Thirty-second Willard Gibbs Medal awarded to Prof. C. A. Elvehjem, 471
can Institute of Physics: Report to Physicists, 397
rson, G. (Morris, A. C., Munn, L. T., and): The System Ethanol-Methanol at 40°, 142
on, Sir John: Science and Government, 219; *erratum*, 249
ence and the Citizen, 382
de, Prof. E. N. da C.: Newton and the Apple, 84
ected president of the Physical Society for 1943–44, 584
w, G., and Arkell, A. J.: A Middle Pleistocene Discovery in the Anglo-Egyptian Sudan, 226
ow, R. C.: Agricultural Education in Great Britain, 143
wes, Dr. C. H.: Influenza Pandemics, Looking Back and Forward, *review*, 263
munity to Viruses, 551
Welfare, Universities Federation for: Welfare of Laboratory Animals, 723
on, Sir Edward V.: A Simple Method of Demonstrating the Circular Polarization of Ionospherically Reflected Radio Waves, 250
adio Exploration of the Ionosphere, 497
rd, Rollo: *Obituary* by Dr. P. Dunsheath, 327
Dr. H. Souza: Transmission of Leprosy by Ticks, 337
ld, W. J., and others: The Ultracentrifuge, *review* by J. St. L. Philpot, 485
ects (Naval), Institution of: Scholarships in Naval Architecture and n Marine Engineering, 20
old Medal for 1942 awarded to W. C. S. Wigley, 276
akeham Prize for 1942 awarded to N. Hancock, 276
nolarship for research in the application of light alloys to ship construction, 303
telian Society: Presidential Address by Prof. Morris Ginsberg on The Individualist Basis of International Law and Morals, 648
elian Society (London and Home Counties Branch of the Institute of Physics, the), and the Mind Association: Symposium on The New Physics and Physical Materialism, 686
, A. J. (Andrew, G., and): A Middle Pleistocene Discovery in the nglo-Egyptian Sudan, 226
rong, Edward A.: Bird Display, *review* by B. W. Tucker, 542
rong, Dr. E. F.: A Century of Progress—Men, Manners, Inventions, 257
ong-Jones, Sir Robert: *Death* of, 164
Arthur: Switchgear Practice, *review*, 572
Dr. A. H. M.: Eddy Current Losses in Single-Conductor Paper-Insulated Lead-Covered Unarmoured Cables of a Single-Phase System, 88

Arts, Royal Society of: Atkinson Memorial Lecture on Industrial Research in Great Britain, a Policy for the Future (Dr. P. Dunsheath), 259
  Albert Gold Medal for 1943 awarded to Sir John Russell, 611
  Peter Le Neve Foster Lecture on Magnesium (Dr. C. H. Desch), 692
Aschaffenburg, Dr. R.: Determination of the Osmotic Pressure of Biological Fluids, 169
Ashbridge, Sir Noel: Short-Wave Broadcasting, Ten Years Technical Progress, 17
Asmous, Vladimir C.: Willibald von Besser (1784–1842), 731
Assheton, R.: Appointed chairman of a committee to consider the Training of Civil Servants, 361
Astbury, Dr. W. T. (Bailey, Dr. K.), and Rudall, Dr. K. M.: Fibrinogen and Fibrin as Members of the Keratin-Myosin Group, 716
Astronomical Society (Royal): Dr. H. Spencer Jones awarded the Gold Medal of the, 331, 361
  Election of officers for the ensuing year, 446
Athenæum: Elections under Rule II, 106; 221
Atkins, Dr. W. R. G.: Vitamin C Saturation Test of Harris and Abbasy, 2
  Obituary of Dr. E. J. Allen, 48
  Determination of the Water Content of Wood and other Substances by means of Ternary Azeotropic Mixtures, 449
Atreya, Dr. B. L.: Supernormal Factors in Human Personality, 556
Aurin, F. L.: Memorandum to Members of the National Service Committee of the American Association of Petroleum Geologists, 119
Aykroyd, Dr. W. R.: Stability of Ascorbic Acid in Dehydrated Vegetables, 22

BABCOCK, E. G., Stebbins, G. L., and Jenkins, J. H.: Evolutionary Processes in Crepis, 701
Bach, Dr. S. J., and Williamson, S.: Urea Synthesis in Mammalian Liver, 23
Bacharach, A. L.: Workers in the Medical Sciences, 145
Backs to the Land Club: Discussion on Livestock Management and Public Health, 417
Bacteriologists (Agricultural), Society of: Annual Conference, 172
Baden-Powell, D. F. W., and Moir, J. Reid: New Palæolithic Industry from the Norfolk Coast, 26
Bahl, K. N.: Nephridia of Earthworms, 112
Baikov, Alexander: Programme for 1943 of the Academy of Sciences of the U.S.S.R., 129
Bailey, Dr. K., Astbury, Dr. W. T., and Rudall, Dr. K. M.: Fibrinogen and Fibrin as Members of the Keratin-Myosin Group, 716
Baillieu, Sir Clive (Batt, W. L., and): Report on the work of the Combined Raw Materials Board to January 26, 1943, 452
Baker, Rev. Canon A. E.: Science, Christianity and Truth, *review* by the Rev. J. C. Hardwick, 710
Baker, Frank, and Enticknap, John: Phagocytosis in the Appendix of the Rabbit, 532
Baker, Dr. H. F.: Non-Singular Cubic Surfaces, *review*, 39
Baker, Squadron-Leader J. N. L.: The 'Friendly' Arctic, *review*, 264
Baker, W. (Abraham, E. P., Chain, E.), and Robinson, Sir Robert: Penicillamine, a Characteristic Degradation Product of Penicillin, 107
Bakst, Aaron: Mathematics, its Magic and Mastery, *review*, 265
Bald, J. G., and Pugsley, A. T.: Potato Virus Diseases in Victoria, 501
Baldwin, Henry Ives: Forest Tree Seed of the North Temperate Regions, with Special Reference to North America, *review* by T. Thomson, 93
Balfour, Lady: Food and Pregnancy, 321
Bamber, T. F.: Appointed research assistant in mining in the University of Sheffield, 584
Bamford, Dr. C. H.: Quantum Statistics, Chemical Equilibria and Reaction Kinetics, *review*, 320
Banks, Sir Joseph (1743–1820): (John D. Griffith Davies), 181
Bannister, F. A.: Awarded a moiety of the Lyell Fund of the Geological Society, 164
Bannister, F. A., and Lonsdale, Dr. K.: Laboratory Synthesis of Diamond, 334
Barber, Dr. H. J., Slack, R., and Wien, R.: Increase in Toxicity of Stilbamidine Solution on Exposure to Light, 107
Barclay, Miss M. G., Burawoy, Dr. A., and Thomson, G. H.: A New Method of Nuclear Methylation of Aromatic Amines and Phenolic Substances, 615
Barcroft, Sir Joseph: Food and Pregnancy, 321
  Chemical Background of Growth, *review*, 402
  Minimum Human Requirements and the Beveridge Report, 422
  Appointed chairman of a Committee on Nutrition Surveys, 444
Barcroft, Sir Joseph, McAnally, Rachel, and Philippson, Andrew: Physiological Action of Acetic Acid in Living Tissues, 304
Barkas, W. W., Hearmon, R. F. S., and Pratt, G. H.: Electrical Resistance of Wood, 83
Barker, A. N.: Studies of Wild Populations, 71
Barker, G. H., and Hancock, A. L.: Boiler-House Measurements and Control, 220
Barker, G. R. (Gulland, Prof. J. M.), and Jordan, D. O.: Configuration of Purine Nucleosides, 109
Barnard, E.: Appointed principal assistant secretary in the Department of Scientific and Industrial Research, 446
Barnes, Dr. H. F.: Studies in Wild Populations, 71
Barou, Dr.: Co-operative Systems in European Agriculture, 523
Barron, Dr. Harry: Synthetic Rubber, 170
Bartell, Prof. Floyd E., and Kistler, Dr. S. S. (edited by Dr. Elmer O. Kraemer, in collaboration with): Advances in Colloid Science, Vol. I, *review* by Prof. H. W. Melville, 5

Bartlett, Prof. F. C.: Some Current Problems in Visual Functions and Visual Perception (thirteenth Thomas Young Oration), 613
Bartlett, Dr. R.: Classification of Rheological Properties, 198
Bartlett, Dr. S., and Edwards, Dr. J.: Artificial Insemination Centres for Dairy Cows, 114
Bateman, A. J.: Science, Common Sense and Decency, 450
Batt, W. L., and Baillieu, Sir Clive: Report on the work of the Combined Raw Materials Board to January 26, 1943, 452
Baweja, K. D.: Studies of Wild Populations, 71
Bayley, Dr. W. S.: *Death* of, 636
Baynes, Dr. H. G.: Authoritarianism versus Individuality, *review*, 597
  Psychology of a Primitive People, *review*, 711
Beams, J. W., and others: The Ultracentrifuge, *review* by J. St. L. Philpot, 485
Beaver, C. J., and Davey, E. L.: The High-pressure Gas-filled Cable, 669
Bedson, Prof. P. P.: *Death* of, 415; *obituary* by Prof. G. R. Clemo, 496
Beevers, Dr. C. A. (Fürth, Dr. R., and): The Encephalophone, a New Method for Investigating Electro-Encephalographic Potentials, 110
Begg, James L.: Clough Memorial Medal of the Edinburgh Geological Society for 1941–1942 presented to, 79
Beirne, B. P.: Distribution and Origin of British Lepidoptera, 701
Bell, Dr. A. E.: The Concept of Energy, 519
Bell Telephone Laboratories: Murray Hill Laboratory of (Franklin L. Hunt), 674
Benedicts, C. (Löfquist, H., and): Great Iron Boulder from Ovifak, 26
Benford, James R.: Bausch and Lomb Artificial Star Projector, 192
Bernal, Prof. J. D.: Future Developments in X-Ray Crystallography, 248
Berridge, Dr. N. J.: Pure Crystalline Rennin, 473
Bertram, C. K. Ricardo, Borley, H. J. H., and Trewavas, Ethelwynn: Report on the Fish and Fisheries of Lake Nyasa, *review* by Michael Graham, 655
von Besser, Willibald (1784–1842): (Vladimir C. Asmous), 731
Bhaduri, P. N.: Cytology of *Rhoeo discolor* and Tradescantia, 56
Bhatnagar, Sir Shanti Swarupa: Elected a fellow of the Royal Society, 358
  Work of, 358
Bibby, Cyril: *Obituary* of Dr. H. G. Stead, 273
  The Methods of Health Education, 498
Bicanic, Dr. R.: Co-operative Systems in European Agriculture, 523
Bickley, Dr. W. G.: Applications of Elementary Mathematics, *review*, 626
Bigwood, Prof. E. J.: Function and Future of Universities, 466
Bining, Arthur C., and others: Education for Citizen Responsibilities, 483
Binnie, A. M., and Green, J. R.: Electrical Detector of Condensation in High-Velocity Steam, 283
Biondi, F. J.: Recording Plastometer for Organic Plastics, 142
Biringuccio, Vannoccio: The Pirotechnia of (translated from the Italian by Cyril Stanley Smith and Martha Teach Gnudi), *review* by Prof. John Read, 569
Bisby, G. R.: Mycological Nomenclature, 303
Biswas, Dr. Kalipada: Systematic and Taxonomic Studies on the Flora of India and Burma, 580
Blackett, Prof. P. M. S.: The Rehabilitation of Fundamental Research, 157
Blacklock, Prof. D. B.: *Obituary* of Prof. Warrington Yorke, 581
Blakemore, F.: Industrial Fluorosis of Animals in England, 30
Blakeslee, Albert F., and others: Cytology, Genetics and Evolution, *review* by Dr. C. D. Darlington, 180
Blandford, A. R.: Air-Blast Circuit-Breakers, 453
Blewett, M. (Fraenkel, Dr. G., and): Vitamins of the B-Group required by Insects, 703
Boas, Prof. Franz: *Death* of, 49; *obituary* by Prof. H. J. Fleure, 75
Boddy, Dr. R. G. H. B.: Microscope Observations of the Crushing of Coal, 54
Bogen, Dr. Emil: Alcohol and Tuberculosis, 477
Bogue, Prof. J. Yule: Applied Photography, 718
Boon, Prof. A. A.: *Death* of, 471; *obituary* by Prof. F. J. Wilson, 609
Booth, H. S., and Martin, D. R.: Systems with Boron Trifluoride, 113
Borley, H. J. H. (Bertram, C. K. Ricardo), and Trewavas, Ethelwynn: Report on the Fish and Fisheries of Lake Nyasa, *review* by Michael Graham, 655
Born, Prof. Max: Density of Frequencies in Lattice Dynamics, 197
Borremans, M.: Co-operative Systems in European Agriculture, 523
Boswell, Prof. P. G. H.: Resignation as general treasurer of the British Association, 418
  Geology in Post-War Planning, 493
Botanic Gardens (Royal), Kew: Prof. E. J. Salisbury appointed director of, 639, 666
Bourne, Aleck: Food and Pregnancy, 321
Bowen, Dr. Ira Sprague: Awarded the Henry Draper Medal for 1942 of the U.S. National Academy of Sciences, 721
Bowhill, Air Chief Marshal Sir F. W.: To be in charge of an Air Transport Command within the R.A.F., 360
Bowie, Dr. J. A.: Training for Industrial Management, 340
Bowman, Dr. Isaiah: Elected president of the American Association for the Advancement of Science, 639
Boyes-Watson, Joy, and Perutz, M. F.: X-Ray Analysis of Hæmoglobin, 714
Boyland, Dr. E.: Nineteenth Annual Report of the British Empire Cancer Campaign, 451
Boys, Sir Charles: Mechanical Lighters, 336
Bradford, Enid A. M. (Crowe, Dr. H. Warren, and): Winter Sources of Vitamin C, 505
Bradley, Dr. A. J.: X-Ray Analysis in Industry, 506
Bragg, Sir Lawrence: The Position of Scientists after the War, 157
  Science and the Citizen, 382
  X-Ray Analysis in Industry, 506
  Seeing Ever-Smaller Worlds, 545
  Joins the Council of the Gas Research Board, 695
Braithwaite, R. B.: The New Physics and Physical Materialism, 686
Brammall, Prof. A.: Awarded the Murchison Medal of the Geological Society, 164
Breuil, Abbé Henri: Elected an honorary Fellow of the Royal Society of South Africa, 639
Brewer, H.: Public Appreciation of Science, 534
Bridgman, W. B., and others: The Ultracentrifuge, *review* by J. St. L. Philpot, 485
Brightman, R.: Atlantis Revisited, *review*, 121
  The British Tradition, *review*, 543
Brind, T. H.: Scientists of the United Nations and the War Effort, 58
Brindley, Dr. G. W.: X-Ray Analysis in Industry, 506
Brinkmann, jun., August: A New Land Nemertean, 253
Briscoe, H. V. A. (Winter, E. R. S., and): Heavy Oxygen, 142
British Association for the Advancement of Science: Sir Harold Hartley appointed general treasurer, 418
  Resignation of Prof. P. G. H. Boswell as general treasurer, 418
  Seismological Tables (Dr. H. Jeffreys and Dr. K. E. Bullen), 472
British Association for the Advancement of Science (Division for the Social and International Relations of Science): Conference on Science and the Citizen, 191, 382, 595, 607
  Conference on Science and the Citizen:—
    News and Views from the Scientific Front (Sir Richard Gregory), 517
    Presentation of Science to a General Public (Dr. Arnold Raestad), 547
  Conference on Co-operative Systems in European Agriculture, 418, 523
British Association for Commercial and Industrial Education: Report of a Conference on Part-time Day Education for the Adolescent, 567
British Chemical Manufacturers (Medical Research Council and the Association of): Conference on the Sterilization of Sulphanilamide Powder, 389
British Coal Utilization Research Association: Conference on the Ultra-fine Structure of Coals and Cokes, with special reference to the Application of Modern Physical Methods, 613
British Council: Appeal for books, 275
  To establish Institutes in the four West African Colonies, 329
    Prof. W. M. Macmillan selected to act as representative in West Africa, 329
British Empire Naturalists' Association (East Staffordshire Branch of the): Report for 1942, 302
British Laboratory Ware Association, Ltd.: Formation of a Technical Committee, 249
British Psychological Society: Symposium on Mental Attitudes in Time of War, 684
British Rheologists' Club and the Manchester Section of the Institution of the Rubber Industry: Conference on the Rheology of Rubber, 563
British School at Athens: The Annual of the, No. 38: Session 1937–38; No. 39: Session 1938–39, *review* by Prof. John L. Myres, 69
British Social Hygiene Council: Vacation School on Social Biology, 389
Broadbent, H. W.: Training for Industrial Management, 340
Broda, Dr. E.: Mode of Chemical Action of X-Rays on a Non-Aqueous Solution, 448; *erratum*, 530
Brody, H. W. (Marshall, G. E., Childers, N. F., and): Effects of Leafhopper Feeding Injury on Apparent Photosynthesis and Transpiration of Apple Leaves, 477
Brooks, Prof. J. L.: A Myrmecophilous Woodlouse, 675
Broughton, Dr. Geoffrey (Lewis, Prof. Warren K., Squires, Lombard, and): Industrial Chemistry of Colloidal and Amorphous Materials, *review* by Prof. F. G. Donnan, 289
Brown, Dr. G. Burniston: Absolute Time and Space, 85
Brown, H. C., and Groot, C.: Preparation of Deuterium Chloride, 57
Browne, Sir Buckston: Darwin's Health, 14
Browning, Prof. Andrew: British Political Institutions, *review* by R. Brightman, 543
Brownlee, G. (Walton, E., and): Isomers of Stilboestrol and its Esters, 305
Buckley, Dr. H.: Elected president of the Illuminating Engineering Society, 639
Buer, Dr. Mabel C.: *Death* of, 49
Buist, J. M. (Seymour, R. C., and): The Position of the Rubber-like State on the Plastic-elastic Scale, 563
Bullen, Dr. K. E. (Jeffreys, Dr. H., and): Seismological Tables, 472
Bullough, Dr. W. S.: Autumn Sexual Behaviour and the Resident Habit of many British Birds, 531
Bunn, C. W.: Towards Atomic Photography, 506
Bunny, Joseph: *Death* of, 357
Burawoy, Dr. A. (Barclay, Miss M. G.), and Thomson, G. H.: A New Method of Nuclear Methylation of Aromatic Amines and Phenolic Substances, 615
Burch, Dr. C. R.: Awarded the Duddell Medal for 1942 of the Physical Society, 218
Burdette, Franklin L. (edited by): Education for Citizen Responsibilities, 483
de Burgh, Prof. W. G.: Science as a Humanity, 607
  International Law and Morals, 648
Burke, A.: Some Problems in Transmission-Line Design, 106
Burke, Frederick, and Carter, John R.: A Diatom New to Britain, 672
Burkitt, M. C.: North-West African Prehistory, *review*, 36
  Archæology and Modern Man, *review*, 515
Burnet, F. M., and Clark, Ellen: Influenza, a Survey of the last 50 Years in the Light of Modern Work on the Virus of Epidemic Influenza, *review* by Dr. C. H. Andrewes, 263
Burns, Prof. D.: Physical Fitness of School Children in South Africa, 704
Burns, P. F.: First Steps in Astronomy without a Telescope, *review*, 151
Burrard, Sir Sidney: *Death* of, 328; *obituary* by Sir Gerald Lenox-Conyngham, 414; note by Prof. J. L. Simonsen, 501
Burt, Sir Bryce Chudleigh: *Death* of, 49;
Burt, Prof. Cyril: Juvenile Crime, *review*, 291
Busvine, Dr. J. R.: The Search for New Insecticides, 690
Butler, Sir Edwin: *Death* of, 415; *obituary* by E. W. Mason, 552
Buxton, Prof. P. A.: Studies of Wild Populations, 71
  Elected a Fellow of the Royal Society, 358

CADBURY, Councillor Paul: Reconstruction in Birmingham and the West Midlands, 667
Cadman, C. H.: Genetics of the Potato, 26
Cadzow, C. J. M.: Co-operative Systems in European Agriculture, 523
Cajander, Prof. A. K.: *Death* of, 133
Calder, Ritchie: Science and the Citizen, 382
Caldwell, Prof. W.: *Death* of, 49
Calkins, Prof. Gary N.: *Death* of, 471
Callow, H. J. (Thompson, J. H., Holt, Dr. P. F., and): Inhibition of Tumour Growth, 364
Calman, Dr. W. T.: John Ray, Naturalist (Rev. Dr. Charles E. Raven), *review*, 457
Cammaerts, Prof. Emile: Elected a member of the Athenæum, 106
Campbell, Ian D.: Nature of Entropy, 138
Campbell, Dr. Neil: *Obituary* of Dr. H. Gordon Rule, 665
Campbell, Dr. Norman R.: Discoveries by Accident, 25

Campos, Dr. Moura: Vitamin Content of Brazilian Foods, 584
Canada, National Research Council of: Work of the, 255
Cannon, C. G., and George, Dr. W. H.: Refractive Index of Coals, 53
  Optical Dispersion for Coals, 225
Cannon, Dr. W. B.: The Body as a Guide to Politics, 77
Carnegie Corporation of New York: Report for the year ending September 30, 1942, 536
Carnegie Trust for the Universities of Scotland: Forty-first annual report for the year 1941–42, 694
Carpenter, Prof. G. D. H.: Observations and Experiments in Africa by the late C. F. M. Swynnerton on Wild Birds eating Butterflies and the Preferences Shown, 173
  The Relative Frequency of Beak Marks on Butterflies of Different Edibility to Birds, 173
Carr, Dr. Francis H.: *Obituary* of Dr. Henry Forster Morley, 608
Carr-Saunders, Prof. A. M.: Appointed to the Colonial Research Committee, 276
Carr-Saunders, Prof. A. M., Mannheim, Hermann, and Rhodes, E. C.: Young Offenders, an Enquiry into Juvenile Delinquency, *review* by Prof. Cyril Burt, 291
Carter, Dr. G. S., Mann, Dr. F. G., Harley-Mason, J., and Jenkins, G. N.: Paraxanthine as a Natural Antithyroid Substance, 728
Carter, John R. (Burke, Frederick, and): A Diatom New to Britain, 672
Cartwright, Rev. Dr. Edmund: Bicentenary of the birth of, 472
Carver, Dr. George Washington: *Death* of, 76
Casey, R. G.: Colonial Policy, 219
Cassin, Prof. R.: Scientists of the United Nations and the War Effort, 58
Casson, Lieut.-Col. Stanley: Greece, 77
Catcheside, D. G. (Lea, D. E., and): Effect of Irradiation on Tradescantia, 338
Catlin, Prof. George: Anglo-American Union as a Nucleus of World Federation, 77
Caton-Thompson, Miss G.: Arabia Felix, *review*, 375
Caulcutt, Sir John: Appointed to the Colonial Research Committee, 276
Cave-Browne-Cave, Wing Commander T. R.: *Obituary* of Prof. J. Eustice, 357
Central Advisory Council for Adult Education in H.M. Forces: Report for April–September 1942, 648
Chadwick Trustees: Offer of prizes for three essays, 530
Chain, E. (Abraham, E. P.), Baker, W., and Robinson, Sir Robert: Penicillamine, a Characteristic Degradation Product of Penicillin, 107
Chandrasekhar, S.: Principles of Stellar Dynamics, *review* by Sir Arthur Eddington, 91
Chao-Lun, Prof. Tseng: Open letter to British scientific men, 612
Chapman, Prof. S.: Scientists of the United Nations and the War Effort, 58

Oropeza, Dr. Pastor : Maternal and Child Welfare in Venezuela, 221
Orowan, Dr. E. : X-Ray Analysis in Industry, 506
Owen, P. C. : Appointed assistant conservator of forests, Sierra Leone, 557
Oxley, T. A., and Henderson, Dr. F. Y. : Automatic Separation of Wet from Dry Grain for Storage, 223

PACKAGING Research Committee : Formed by the Printing and Allied Trades Research Association, 220
Page, Sir Archibald : Awarded the Faraday Medal of the Institution of Electrical Engineers, 191
Page, Dr. James E. (Lauchlan, A. D. Elmsly, and) : A Modified Calomel Cell for *p*H Measurements, 84
Paget, Sir Richard : A World Language, 80
Palæontographical Society : Tributes paid to Sir Arthur Smith Woodward on his retirement from the presidential chair, 501
  Prof. H. L. Hawkins elected president, 501
Pallot, A. C. : Thermal Insulation at Medium Temperature, 593
Palmer, R. A. : Co-operative Systems in European Agriculture, 523
Paltridge, T. N. (McTaggart, A., and) : New Farm Crops for Australia, 445
Pares, Sir Bernard : Elected a member of the Athenæum, 221
Park, H. E. : A Variant of Maxwell's Experiment on the Movement of Magnets about a Straight Conductor, 697

Parker, Dr. A. : Appointed director of fuel research in the Department of Scientific and Industrial Research, 446
Parliamentary and Scientific Committee : 156
  Annual Report for 1942, 219 ; *erratum*, 249
  Lord Samuel appointed president for 1943, 219
  Report on Coal Utilization Research and the National Economy, 709
Parnas, Prof. J. K. : Co-Enzymatic Reactions, 577
Parr, G., and Walter, W. Grey : Amplifying and Recording Technique in Electro-Biology, 330
Parsons, Dr. F. G. : *Death* of, 328 ; *obituary* by Prof. F. Wood Jones, 415
Parsons, Sir John : Light and Vision, 638
Pascoe, K. J. (Stokes, A. R.), and Lipson, Dr. H. : X-Ray Evidence of the Nature of Cold Work in Metals, 137
Paterson, Dr. C. C. : *Obituary* of Lord Hirst, 218
Patino-Camargo, Dr. Luis : Murine Typhus in Bogotá, 445
Paton, Lieut. W. Neil : *Obituary* by Prof. A. C. Hardy, 48
Pattee, Alida Frances : Vitamins and Minerals for Everyone, *review*, 572
Patterson, Ernest Minor, and others : Education for Citizen Responsibilities, 483
Pattison, I. H. : Appointed veterinary officer, Palestine, 20
Pattle, R. E. (Weddell, Dr. G., Feinstein, Dr. B., and) : Onset of Fibrillation in Denervated Muscle, 449
Paul, R. W. : *Death* of, 387 ; *obituary* by R. S. Whipple, 470 ; bequests of, 695
Pear, Prof. T. H. : Are there Human Instincts ?, *review* by Dr. R. H. Thouless, 489
  Place of Psychology in the Sciences, 638
  Re-educating the Germans, 684
Pearse, Prof. A. S. : Introduction to Parasitology, *review*, 264
Pease, Robert N. : Equilibrium and Kinetics of Gas Reactions, *review* by Dr. C. H. Bamford, 320
Peek, B. M. : Formation of Planetary Systems, 200
  Activity on Jupiter's South Equatorial Belt, 331
Penfield, Prof. Wilder : Elected a fellow of the Royal Society, 358
Penionzhkevich, E. : Death-rate Variation in Fowls and Geographical Latitude, 644
Penrose, Miss F. E. : Coloured Arc in the Sky, 300
Perutz, M. F. (Boyes-Watson, Joy, and) : X-Ray Analysis of Hæmoglobin, 714
Petrie, G. F., and Steabben, D. : Identification of Clostridia of Gas Gangrene, 644
Pevtich, —. : Scientists of the United Nations and the War Effort, 58
Philip, Dr. U. : Studies of Wild Populations, 71
Phillipson, Andrew (Barcroft, Sir Joseph, McAnally, Rachel, and) : Physiological Action of Acetic Acid in Living Tissues, 304
Philpot, J. St. L. : American Work on the Ultra-centrifuge, *review*, 485
Photographic Society (Royal) : Hurter and Driffield Memorial Lecture (Dr. S. O. Rawling), 210
  (Scientific and Technical Group), Symposium on Aspects of Photomicrography, 367
Photography (Scientific), Association for : Formation of, 443
  First meeting, 718
Physical Society : Charles Chree Medal and Prize for 1943 awarded to Prof. B. F. J. Schonland, 218
  Duddell Medal for 1942 awarded to Dr. C. R. Burch, 218
  Election of officers for 1943–44, 584
  Twenty-seventh Guthrie Lecture by Prof. E. T. Whittaker on Chance, Freewill, and Necessity in the Scientific Conception of the Universe, 612
  Thirteenth Thomas Young Oration to be delivered by Prof. F. C. Bartlett, 613
  (Colour Group) : Discussion on Luminescence and Colour, 73
Physics, Institute of : Conference on X-Ray Analysis in Industry, 248, 506
  (Electronics Group) : Opening paper by Dr. H. Frohlich of a discussion on Dielectric Breakdown and other Electronic Processes in Solids, 339
  (London and Home Counties Branch), the Aristotelian Society and the Mind Association : Symposium on The New Physics and Physical Materialism, 686
Piaggio, Prof. H. T. H. : Non-Euclidean Geometry, *review*, 94
Pickering, Dr. W. H. (Millikan, Dr. R. A., Neher, Dr. H. V., and) : Origin of Cosmic Rays, 663
Pilgrim, Dr. G. E. : Elected a fellow of the Royal Society, 358
Pilgrim Trust : Purchase of the residue of Newton's Library, 446
Pittock, F. J. : Aspects of Photomicrography, 367
Planning (Political and Economic) : Summary of activities during the last twelve years, 372
Planning and Regional Reconstruction, Association for : Regional Boundaries in Great Britain, 584
Plimmer, Prof. R. H. A., and Plimmer, Violet G. : Food, Health, Vitamins, ninth edition, *review*, 572
Polanyi, Prof. M. : Resonance and Chemical Reactivity, 96
Polish Institute of Arts and Sciences in America : *Bulletin* No. 1, 499
Polish Technicians in Great Britain, Association of : Special tercentenary celebration of Isaac Newton, 133
Political and Economic Planning : Summary of activities during the last twelve years, 372
Polunin, Dr. Nicholas : Potatoes and War Economy, 587
  Early Collections of Arctic Plants, 645
Polychroniades, —. : Co-operative Systems in European Agriculture, 523
Potter, J. M. S. : Fruit from the Garden, 20
Powell, Sir Allan : Science and the Citizen, 382
Powell, H. M. (Clark, D., and) : X-Ray Spectrum of Phosphorus Pentachloride, 27
Poxon, D. W. (Whitworth, Dr. C., and) : Detection of Acid of Basic Substances in Damaged Fabrics, 198
Pratt, G. H. (Barkas, W. W., Hearmon, R. F. S., and) : Electrical Resistance of Wood, 83
Pratt, Sir John : Great Britain and China, 77
Predtechensky, S. A. : *Death* of, 554
Preston, G. D. : Appointed to the Harris chair of physics at University College of Dundee, 610 ; Work of, 610
Preston, G. D., and Trotter, J. : A Change of Symmetry with Temperature, 166
Pringle, W. J. S. (Greer, E. N., Mounfield, J. D., and) : Estimation of Added Calcium Carbonate (Creta Præparata) in National Flour, 27
Printing and Allied Trades Research Association : Formation of a Packaging Research Committee, 220
Professors and Lecturers (University) of Allied Countries, Association of : Third General Meeting, 229
  Conference on the Function and Future of Universities, 389, 466
Pruden, H. M. : Coastal Radio Telephone, 732
Pruett, J. Hugh : The Portland Meteor and Resulting Meteorite, 192
Public Analysts and other Analytical Chemists, Society of : Election of officers and council for 1943, 303
Public Health and Hygiene, Royal Institute of : The Harben Gold Medal awarded to Sir Henry Dale, 446
Public Library of South Australia : First Report of the, 248
Pugsley, A. T. (Bald, J. G., and) : Potato Virus Diseases in Victoria, 501
Pushkarnath, —. : Incompatibility in Solanum, 338
Pyke, Dr. Magnus : Co-operative Systems in European Agriculture, 523
  Four Years of Planned Feeding in Great Britain, 658

QUEEN, Stuart A., and others : Education for Citizen Responsibilities, 483
Quiggin, A. Hingston : Haddon, the Head Hunter, *review* by Dr. C. S. Myers, 4

RAESTAD, Dr. Arnold : Science and the Citizen, 382
  Presentation of Science to a General Public, 547
R.A.F. : Creation of an Air Transport Command within the, 360
  Air Chief Marshal Sir F. W. Bowhill to be in charge of, 360
Raman, Sir C. V. : Nature of the Liquid State, 478
Ramchandra Rao, Rao Bahadur Y. : Locusts and other Migratory Insects in India, 509
Ramsbottom, J. : Mycological Nomenclature, 303
Ranke, Hermann, and others : Studies in the History of Science, *review* by Dr. W. H. S. Jones, 404
Raphael, F. Charles : Electrical Installations in Hospitals, 557
Rastall, Dr. R. H. : Terminology in the Geological Sciences, 294, 447
Raven, Rev. Dr. Charles E. : John Ray, Naturalist, *review* by Dr. W. T. Calman, 457
Rawling, Dr. S. O. : Sensitometry since Hurter and Driffield, 210
Rawlins, F. Ian G. : The National Gallery in War-time, 123
  Work of (Sir Kenneth Clark), 133
  Artists' Materials and Methods, *review*, 262
Ray (John), Naturalist : (Rev. Dr. Charles E. Raven), *review* by Dr. W. T. Calman, 457
Rây, Prof. R. : A New Type of Complex Silver Compounds with Tervalent Silver, 643
Ray Society : Re-election of the officers and council for the current year, 389
Rayleigh, Lord : The Life of Sir J. J. Thomson, *review* by Sir William Dampier, 120
  Shape of Pebbles, 338
  Laboratory Synthesis of Diamond, 394
Raymont, T. : Education as a Scientific Study, *review*, 460
  Problems of American Unity, 677
Rea, E. : Agricultural Education in Great Britain, 143
Read, Prof. H. H. : Geology and Geologists in the War and the Peace, 119
Read, Prof. John : Czechoslovak Medical Students at Oxford, 366
  Molecular Tinkering and Tailoring, *review*, 488
  Biringuccio in English, *review*, 569
Redikorzev, V. E. : *Death* of, 554
Regan, Dr. C. Tate : *Death* of, 76 ; *obituary* by Dr. E. Trewavas, 188
Reichardt, A. N. : *Death* of, 554
Reid, D. M. : Occurrence of Crystals in the Skin of Amphipoda, 504
Reyersbach, C. D. : Sub-standard Kine-photomicrography, 720
Reynolds, J. M. : Effect of Parental Feeding on the Rate of Development and Mortality of *Tribolium destructor* Uyttenboorgaart (Coleoptera, Tenebrionidæ), 55
Reyrolle and Co., Ltd., A. : The Making of an Engineer, *review* by Prof. Willis Jackson, 570
Rhodes, E. C. (Carr-Saunders, A. M., Mannheim, Hermann, and) : Young Offenders, an Enquiry into Juvenile Delinquency, *review* by Prof. Cyril Burt, 291
Richmond, Admiral Sir Herbert : War at Sea To-day, 77
Riley, Dr. D. P. : X-Ray Analysis in Industry, 506
Riley, Dr. D. P. (Lipson, Dr. H., and) : Absolute X-Ray Wave-lengths, 250, 502
Rimington, Dr. C. : Formation of Porphyrin by Autolysing Yeast and by Yeast Press Juice, 393
Ripper, Dr. W. : Studies of Wild Populations, 71
Rishbeth, Mrs. K. : The Polynesians, *review*, 599
Ritchie, Prof. A. D. : The Logic of Question and Answer, 498
Rios, Dr. Juan Antonio : Public Health in Chile, 668
Roaf, Prof. H. E. : Marvels of the Vertebrate Eye, *review*, 236
Roberts, J. A. Fraser (Prof. R. A. Fisher and) : A Sex Difference in Blood-Group Frequencies, 640
Roberts, R. A. : *Death* of, 415
Roberts, Col. W. R. : Flora of the Egyptian Wadis near Cairo, 20
Roberts-Austen, Sir William Chandler : The life and work of (Dr. S. W. Smith), 136, 350
Robertson, Dr. J. D. : Calcium Metabolism and Nutrition Problems, 379
Robertson, Prof. J. K. : Science and Reconstruction in Canada, 444
Robertson, Prof. J. M. : X-Ray Analysis in Industry, 506
Robertson, Dr. Madge E. : Apparent Stimulative Effect on Mould Growth of a Mercurial Preparation, 365
Robertson, Robert H. S., and Hathaway, H. W. J. : Rheological Series, 728
Robinson, Lady (Medawar, P. B.), and Robinson, Sir R. : A Synthetic Differential Growth Inhibitor, 195
Robinson, Principal : Agricultural Education in Great Britain, 143
Robinson, Sir Robert : Control of Chemical and Mineral Products, 562
Robinson, Sir Robert (Abraham, E. P., Chain, E., Baker, W., and) : Penicillamine, a Characteristic Degradation Product of Penicillin, 107
Robinson, Sir Robert (Dodds, Prof. E. C., and) : Isomers of Stilboestrol and its Esters, 305
Robinson, Sir Robert (Medawar, P. B., Robinson, Lady, and) : A Synthetic Differential Growth Inhibitor, 195

Rockefeller Foundation : Grant to the Royal Society for the publication of scientific journals, 303
Rockefeller Institute for Medical Research and the American Association of Scientific Workers : Greetings exchanged with the Association of Scientific Workers at the Conference on Planning in War and in Peace, 154
Rodwell, F. (Hickling, A., and) : Electrolytic Oxidation of Formaldehyde, 702
Rogers, Dr. M. A. T. : Tetra-Arylazadipyrromethines, a New Class of Synthetic Colouring Matter, 504
Rolfe, R. T. : Steels for the User, second edition, *review*, 600
Rolleston, Dr. J. D. : Folk-Lore of Children's Diseases, 193
  British and Viennese Medical Schools, *review*, 461
  Folk-Lore of Epilepsy, 556
Rooksby, H. P. : X-Ray Analysis in Industry, 506
Rose, C. T. (Miller, R., and) : Joints in Submarine Cables, 248
Rosebury, Dr. T. : The Fuller Utilization of Scientific Resources for Total War, 389
Roskill, O. W. (Hutton, Prof. R. S., and) : Hydro-Electric Development in Great Britain, 335
Roskin, G., and Nastiukova, O. : Vitamin C in the Protozoa, 337
Ross, Alan S. C. : Studia Moritura, 699
Ross, H. McGregor : The Photography of Photo-elastic Stress Patterns, 720
Rotha, Paul : Science and the Citizen, 382
Rothamsted Experimental Station : Dr. W. G. Ogg appointed director, 695
  Work of the new director, 722
Rothen, Alexandre, and others : The Ultracentrifuge, *review* by J. St. L. Philpot, 485
Rotter, Dr. Godfrey : Retirement from the post of director of explosives research, Woolwich, 191
Rounce, N. V. : Appointed senior agricultural officer, Tanganyika Territory, 557
Rowntree, B. S. : Minimum Human Requirements and the Beveridge Report, 422
Royal Arsenal, Woolwich : Retirement of Dr. Godfrey Rotter from the post of director of explosives research, 191
  Appointment of Prof. S. Sugden as superintendent of explosives research, 191
Royal College of Science : *Scientific Journal* of the, 136
Royal Engineers (tunnellers of the) : Discovery of an unknown cavern at Gibraltar, 362
Royal Institution : Actonian Prize for 1942 awarded to Dr. Alexander W. G. Ewing and Mrs. Ewing, 221
Royal Society : Grant from the Rockefeller Foundation for the publication of scientific journals, 303
  New Fellows of the, 358
  Pilgrim Trust Lecture by Dr. Karl T. Compton, 362, 601
  Election of foreign members, 610
Royal Society of Edinburgh : Election of new Fellows, 276
  Makdougall-Brisbane Prize for 1938–1942 awarded to Sir William Wright Smith, 276
  James Scott Prize address for 1943 delivered by Prof. E. A. Milne on The Fundamental Concepts of Natural Philosophy, 530
Rubber Industry, Institution of the (Manchester section) and the British Rheologists' Club : Conference on the Rheology of Rubber, 563
Rudall, Dr. K. M. (Bailey, Dr. K., Astbury, Dr. W. T., and) : Fibrinogen and Fibrin as Members of the Keratin-Myosin Group, 716
Rudra, M. N. : Hexose Dehydrogenase, 641
Rule, Dr. H. Gordon : *Death* of, 497 ; *obituary* by Dr. Neil Campbell, 665
Russell, Dr. Alexander : *Death* of, 133 ; *obituary* by Dr. W. R. C. Coode-Adams, 163
Russell, Dr. E. S. : Trawling and the Stocks of Fish, 323
  The Stereotypy of Instinctive Behaviour, 612
Russell, Dr. E. W. : The Countryside As It Was, *review*, 37, 254
Russell, Sir John : Restarting Agriculture in Devastated Europe, 433
  Co-operative Systems in European Agriculture, 523
  Awarded the Albert Gold Medal for 1943 of the Royal Society of Arts, 611
Rydbeck, Dr. O. E. H. : Radio Fade-Out in Sweden, 700
Ryle, Prof. John Alfred : Elected professor of social medicine in the University of Oxford, 106

SAFETY in Mines Research Board : Twentieth Annual Report (H. Hartley), 284
Sahni, B. : Indian Silicified Plants, I, *Azolla intertrappea* Sahni and H. S. Rao, 338
Salisbury, Prof. E. J. : The Reproductive Capacity of Plants, *review*, 319
  The Flora of Bombed Areas, 462
  Appointed director of the Royal Botanic Gardens, Kew, 639 ; Work of, 66
Salt, George : Studies of Wild Populations, 71
Samuel, Viscount : An Unknown Land, *review* by R. Brightman, 121
  Appointed president for 1943 of the Parliamentary and Scientific Committee, 219
Sanders, A. : Training for Industrial Management, 340
Sandford, M. (Chattaway, F. W., Happold, Dr. F. C., and) : Nutritional Requirements of *C. diphtheriae* and *L. casei*, 559
Saunders, B. C., and Clark, R. E. D. : Order and Chaos in the World of Atoms, *review* by Prof. John Read, 488
Saunders, Dr. O. A. : Theory and Practice of Heat Engines, *review*, 571
Sayles, R. W. : *Death* of, 357
Scheele, Dr. A. : Cancer Control in the United States, 668
Schieber, Dr. —. : Synthetic Textile Research in Germany, 115
Schiebold, Dr. E. S. : Synthetic Textile Research in Germany, 115
Schiller, P. : Towards the 'Correct' Domestic Multi-Part Tariff, 220
Schmidt, Waldo L. : The Genus Aegla, 141
Schnurmann, Dr. Robert : Frictional Properties of Metallic Films, 420
Schonland, Prof. B F. J. : Awarded the Charles Chree Medal and Prize for 1943 of the Physical Society, 218
Schrader, Franz, and others : Cytology, Genetics and Evolution, *review* by Dr. C. D. Darlington, 180
Schukina, L. A. (Shemiakin, Prof. M. M.), and Shvezov, J. B. : Mechanism of Biological Action of Vitamin K and its Synthetic Analogues, 585
Schuman's : Medical Miscellany, List G, 249
Science Library, South Kensington : Services during the War, 611
Scientific Committee, Parliamentary and : 156
  Annual Report for 1942, 219 ; *erratum*, 249
  Lord Samuel appointed president for 1943, 219
  Report on Coal Utilization Research and the National Economy, 709
Scientific Workers, Association of : Conference on Workers in the Medical Sciences, 145
  Conference on Scientists of the United Nations and the War Effort, 58
  Conference on Planning of Science in War and in Peace, 20, 203
    Government and Science in Great Britain (Sir Stafford Cripps), 152, 154
    Message of greeting from the Academy of Sciences of the U.S.S.R., and the Soviet Scientists' Anti-Fascist Committee, 153
  Study course on British Trade Unionism (Dr. J. Kuczynski), 446
  Twenty-sixth Council meeting, 666
    Presidential Address by Sir Robert Watson-Watt, 667
  Aims of the, 667
Scientific and Industrial Research, Department of : Dr. A. Parker appointed director of fuel research, 446
  Mr. E. Barnard appointed principal assistant secretary, 446
  Mr. R. O'F. Oakley and Mr. G. R. D. Hogg appointed assistant secretaries, 446
  Dr. Charles S. Hanes appointed director of food investigation, 530
  Dr. B. A. Southgate promoted to be acting director of water pollution research, 724
Scott, Dr. Hugh : In the High Yemen, *review* by Miss G. Caton-Thompson, 375
Scott, John : Behind the Urals, an American Worker in Russia's City of Steel, *review* by Dr. David Williams, 516
Scott, Dr. J. R. : Rheological Problems in the Rubber Industry, 563
Scott, William B. : Mammalian Fauna of the Duchesne River, 337
Scottish Education Department : Youth Registration in 1942, 652
Segre, B. : The Non-Singular Cubic Surfaces, *review* by Dr. H. F. Baker, 39
Selye, Prof. Hans : An Attempt at a Natural Classification of the Steroids, 662
Semenov, Nikolai : Advances of Chemical Kinetics in the Soviet Union, 185
Seymour, R. C., and Buist, J. M. : The Position of the Rubber-like State on the Plastic-elastic Scale, 563
Shand, W., and Spurr, R. A. : Molecular Structure of Ozone, 645
Shannon, H. A., and Grebenik, E. : The Population of Bristol, *review* by D. Caradog Jones, 514
Shapley, Dr. Harlow : Diameters of Extragalactic Nebulæ, 57
  Science and the Citizen, 382
Sharman. Dr. B. C. : Nucleoli in *Agropyron repens*, Beauv., 170
Sharp, J. H. : Presented with a William Macnab Medal for 1942 of the Institution of Chemical Engineers, 418
Shattock, P. M. F. (Mattick, Dr. A. T. R., and) : Group *N* Streptococci, 278
Shaw, Dr. H. (Montgomery, H. B. S., and) : Behaviour of Thiuram Sulphides, etc., in Spore Germination Tests, 333
Sheffield, F. M. L. (Kassanis, B., and) : Cytoplasmic Inclusions in Virus-infected Plants, 337
Sheffield City Libraries : Bibliography on Management and Labour (Research Bulletin No. 7), 557
Shemiakin, Prof. M. M., Schukina, L. A., and Shvezov, J. B. : Mechanism of Biological Action of Vitamin K and its Synthetic Analogues, 585
Sherrard, G. C. (Olesen, Dr. Robert, and) : Rat Infestation on Vessels, 499
Shipley, J. F. : Protection of Structures against Lightning, 638
Shmuck, A., Smirnov, A., and Ilyin, G. : Formation of Nicotine in Plants Grafted on Tobacco, 338
Shoenberg, Dr. David : Wartime Science in the U.S.S.R., 154
Shryock, Richard H., and others : Studies in the History of Science, *review* by Dr. W. H. S. Jones, 404
Shull, A. F. : Wing Development in Aphids, 477
Shvezov, J. B. (Shemiakin, Prof. M. M., Schukina, L. A., and) : Mechanism of Biological Action of Vitamin K and its Synthetic Analogues, 585
Siegbahn, Prof. Manne : Absolute X-ray Wave-lengths, 502
  X-Ray Analysis in Industry, 506
Sieveking, H. A. : Electrical Aspects of Ferro-Alloy Manufacture, 301
Sigerist, Dr. Henry E. : War and Medicine, 668
Sigerist, Dr. Henry E., and others : Studies in the History of Science, *review* by Dr. W. H. S. Jones, 404
Sil, J. M. : Earthquakes reported to, 136
Silver, Dr. R. S. : H. L. Callendar and the Theory of the Liquid State, 588
Skottsberg, C. : Communities of Marine Algæ in Subantarctic and Antarctic Waters, 26

Travers, S. J. : Agricultural Education in Great Britain, 143
Treloar, Dr. L. R. G. : The Behaviour of Rubber in Elongation, Compression and Shear, 563
    Theory of Large Elastic Deformations, 616
Trenchard, Lord : Colonial Policy, 219
Trewavas, Dr. Ethelwynn : *Obituary* of Dr. C. Tate Regan, 188
Trewavas, Dr. Ethelwynn (Bertram, C. K. Ricardo, Borley, H. J. H., and) : Report on the Fish and Fisheries of Lake Nyasa, *review* by Michael Graham, 655
Trifunovitch, M. : Function and Future of Universities, 466
Tripp, Miss B. M. H. : Science and the Citizen, 382
Trotter, J. (Preston, G. D., and) : A Change of Symmetry with Temperature, 166
Trowell, Dr. O. A. : Liver Vacuoles and Anoxæmia, 730
Trueman, Prof. A. E. : Terminology in the Geological Sciences, 447
    Problems of Geomorphology, *review*, 598
Tucker, B. W. : The Behaviour of Birds, *review*, 542
Tupholme, C. H. S. : Modern Engineering, *review* by Dr. L. E. C. Hughes, 208
Turner, Prof. E. E. (Jamison, Dr. M. M., and) : Asymmetric Transformations, 391
Turner, Lt.-Col. Joseph C. : Development of Cold Agglutinins in Atypical Pneumonia, 419
Turner, Prof. W. E. S. : New Uses for Glass, 173 ; *errata*, 194
Tweedie, M. C. K. (Dale, Dr. W. M., Meredith, W. J., and) : Mode of Action of Ionizing Radiations on Aqueous Solutions, 280
Twyman, F. : The Interferometer in Lens and Prism Manufacture, 43
    Prism and Lens Making, *review* by H. W. Lee, 458

UNILEVER Ltd., and Lever Brothers : The Problem of Unemployment, 344
U.S. National Academy of Sciences : Creation of the Charles L. Mayer Awards for Animal Cell Growth Research, 19
  First Charles L. Mayer prize awarded to Prof. Charles B. Huggins, 637
  Annual Meeting, 721 ; Election of officers and new members, 721 ; Presentation of Medals, 721
Universities Federation for Animal Welfare : Welfare of Laboratory Animals, 723
University of Birmingham : Dr. Alastair Frazer appointed to the chair of pharmacology, 276
  Report of the Vice-Chancellor, 299
University of Cambridge : Prof. A. C. Chibnall appointed Sir William Dunn professor of biochemistry, 557, 610
  Botanic Garden, 328
University of Edinburgh : Retirement of Prof. T. J. Jehu from the chair of geology, 637
  Appointment of Prof. Arthur Holmes to the chair of geology, 637
University of Glasgow: Prof. E. Taylor Jones to retire from the chair of natural philosophy, 446
  Mr. P. I. Dee appointed to the chair of natural philosophy, 446
University of Leeds : Gift of £50,000 from Mr. Henry Ellison for research in pure and applied chemistry and in physics, 303
University of London : Conferment of degrees, 275
  William Julius Mickle fellowship awarded to Prof. E. C. Dodds, 275
  Title of reader in medicine conferred on Dr. Clifford Wilson, 530
University of Oxford : Prof. John Alfred Ryle elected professor of social medicine, 106
University of Santiago : Installation of a new seismograph at the Seismological Institute, 331
University of Sheffield : Gift to provide equipment for the Department of Geology, 331
  Gift of £25,000 from Mr. Henry Ellison for a scientific research fellowship, 418
  Appointments, 584
University of the Witwatersrand : Dr. Bernard H. Knight appointed to the chair of highway engineering, 164
University College of North Wales, Bangor : Dr. E. D. Hughes appointed professor of chemistry, 557, 610
University College, Dundee : Mr. G. D. Preston appointed to the Harris chair of physics, 610
University Professors and Lecturers of Allied Countries, Association of : Third General Meeting, 229
  Conference on the Function and Future of Universities, 389, 466
Unna, P. J. H. : Theory of Sea Waves, 479
Uvarov, Dr. B. P. : An International Anti-Locust Campaign, 41

VALENTINE, J. Manson : Preparation and Preservation of Insects for Collections, 362
Van Name, William G.: American Land and Freshwater Isopod Crustacea, 282
Vand, Dr. V. : Temperature of the Solar Corona, 728
Vaucher, Prof. Paul : Function and Future of Universities, 466
Vaughan, Miss Janet : Appointed a trustee of the Nuffield Trust, 218
Vaughan, N. B. (edited by) : Metallurgical Abstracts (General and Non-Ferrous), Vol. 8, 1941, *review*, 265
  The Journal of the Institute of Metals, Vol. 67, 1941, *review*, 265
Veraart, Prof. J. A. : Function and Future of Universities, 466
Vernon, Dr. H. M. : Hours of Work and their Influence on Health and Efficiency, 651
Vinogradov, A. P. : Biogeochemical Research in the U.S.S.R., 659
Vollmer, Dr. Erwin P. : Relation of Hypopituitarism and Starvation, 698

WADDINGTON, Dr. C. H. : Science and the Citizen, 382
  Polygenes and Oligogenes, 394
  Science and Ethics, *review*, 657
Wade, Dr. S. H. : Presented with the Junior Moulton Medal and Award for 1942 of the Institution of Chemical Engineers, 418
Wadia, D. N. : Awarded the Lyell Medal of the Geological Society, 164
  Science in India, 548
Wakefield, Miss E. M. : Mycological Nomenclature, 303
Walker, A. C. : Abrasion Tests for Textile Threads, 113
Walker, Alan G. : Colonization of Buried Wheat Straw by the Fungus *Fusarium culmorum*, 283
Wallace, William (1768–1843) : 472
Wallersteiner, Dr. W. K. S. : Counteracting Sulphonamide Inhibitors, 586
Wallis, Wilson D., and others : Education for Citizen Responsibilities, 483
Wallner, Dr. L. : Synthetic Textile Research in Germany, 115
Walls, Gordon Lynn : The Vertebrate Eye and its Adaptive Radiation, *review* by Prof. H. E. Roaf, 236
Walter, W. Grey (Parr, G., and) : Amplifying and Recording Technique in Electro-Biology, 330
Walton, E., and Brownlee, G. : Isomers of Stilboestrol and its Esters, 395
Ward, A. G. : Determination of Half-Value Periods, 338
Warren, Jr., S. Reid (Weyl, Charles), and O'Neill, Dallett B. : Radiologic Physics, *review* by Prof. F. L. Hopwood, 348
Waterfield, Reginald L. : The Revolving Heavens, *review*, 265
Watson, H. E. (compiled by) : The Tropical Sky, *review*, 378
Watson, R. W. : Factors in the Production of Leaf Palisade Tissue, 113
Watson, W. Trevor : *Death* of, 387 ; *obituary* by G. S. W. Marlow, 582
Watson-Watt, Sir Robert : Planning of Science in War and in Peace, 153
  Greetings exchanged with the Rockefeller Institute of Medical Research and the American Association of Scientific Workers at the Conference on Planning in War and in Peace held by the Association of Scientific Workers, 154
  Science and the Citizen, 382
  Presidential Address to the Association of Scientific Workers, 667
Watts and Son, Ltd., E. R. : New Universal Bevel Protractor, 78
Wayland, E. J. : A Middle Pleistocene Discovery in the Anglo-Egyptian Sudan, 334
Webb, J. S. : Appointed mineralogist, Nigeria, 557
Weber, V. J. : New Reference Frequency Equipment, 301
Weckler, Jr., J. E. : Polynesians—Explorers of the Pacific, *review* by Mrs. K. Rishbeth, 599
Weddell, Dr. G., Feinstein, Dr. B., and Pattle, R. E. : Onset of Fibrillation in Denervated Muscle, 449
Weems, Lieut.-Comdr. P. V. H. : Air Navigation, British Empire edition, revised and edited by Arthur J. Hughes and P. F. Everitt, second edition, *review*, 572
Wehmeyer, Lewis E. : A Revision of Melanconis, Pseudovalsa, Prosthecium and Titania, *review* by E. W. Mason, 208
Weil-Malherbe, Dr. H., and Weiss, Dr. Joseph : Quenching of Fluorescence by Nitric Oxide, 449
Weintraub, R. L., and McAlister, E. D. : Physiology of the Grass Seedling, 477
Weiss, Dr. Joseph (Weil-Malherbe, Dr. H., and) : Quenching of Fluorescence by Nitric Oxide, 449
Wells, A. F. : X-Ray Spectrum of Phosphorus Pentachloride, 27
Wells, H. G. : Phoenix, a Summary of the Inescapable Conditions of World Reorganization, *review* by Lord Horder, 374

Zlotnik, I. : A Nuclear Ring in the Developing Male Germ Cells of Dog and Cat, 670
Zuckerman, Prof. Solly : Elected a fellow of the Royal Society, 358
Zwicky, Prof. Heinrich : *Death* of, 471

SUBJECT INDEX

ABBASY (Harris and) : Vitamin C Saturation Test of (Dr. W. R. G. Atkins), 21
Abrasion Tests for Textile Threads (A. C. Walker), 113
Absolute Time and Space (Dr. G. Burniston Brown), 85
Absolute X-Ray Wave-lengths (Dr. H. Lipson and Dr. D. P. Riley), 250, 502 ; (Prof. Manne Siegbahn), 502
Absorption and Excretion of Trace Elements (Miss E. M. Widdowson and Dr. R. A. McCance), 30
A.C. Circuits : Automatic Protection of (G. W. Stubbings), third edition, revised, *review* by Dr. L. E. C. Hughes, 683
Accident : Discoveries by (Dr. Norman R. Campbell), 25 ; (Dr. J. C. Chaston), 55
  Scientific Discoveries by (T. Ll. Humberstone), 215
Acetic Acid in Living Tissues : Physiological Action of (Sir Joseph Barcroft, Rachel McAnally and Andrew Phillipson), 304
Acid Strength : The Hydrogen Bond and its Influence on (Rev. Dr. H. O. Jenkins), 561
Acid or Basic Substances in Damaged Fabrics : Detection of (Dr. C. Whitworth and D. W. Poxon), 198
Activities (Human) and Soil Characteristics (Dr. F. E. Kenchington), 83
Actonian Prize of the Royal Institution for 1942 awarded to Dr. Alexander W. G. Ewing and Mrs. Ewing, 221
Adolescent : Part-time Day Education for the (British Association for Commercial and Industrial Education), 567
Advisory Committees : Joint Production and, 156
Aegla : The Genus (Waldo L. Schmidt), 141
Aerial Photographs (A. J. Eardley), *review* by Dr. G. D. Hobson, 459
Aerial Photographs : Map Construction from (Dr. G. D. Hobson), 588
Aeroplane : The First Man-Carrying, 192
Aeroplanes Fly : How (W. O. Manning), *review*, 600
Afghanistan : Investigations in (K. de B. Codrington), 105
Africa (North-West) : The Prehistoric Archæology of (Frederick R. Wulsin), *review* by M. C. Burkitt, 36
Africa (South) : Bored Stones of (A. J. H. Goodwin), 26
  A National Manpower Survey of (E. H. Cluver, E. Jokl and T. W. de Jongh), 704
  Physical Fitness of School Children in (Prof. D. Burns), 704
Africa (West) : Birds of the British List wintering in (A. C. Allnutt), 20,
African History : Events in (Rev. Dr. E. W. Smith), 418
African (North) Natural History, 20
African (North-West) Prehistory, *review* by M. C. Burkitt, 36
Agar from South African Seaweeds (Wm. Edwyn Isaac, M. H. Finlayson and M. Gavine Simon), 532
Agassiz Medal for 1942 of the U.S. National Academy of Sciences awarded to Columbus O'Donnel Iselin, II, 721
'Age' of Terrestrial Matter and the Geochemical Uranium/Lead Ratio (F. F. Koczy), 24
Age Determinations of Intrusive Rocks, Ontario (H. C. Horwood and N. B. Keevil), 701
Agglutinins (Cold) in Atypical Pneumonia : Development of (Lt.-Col. Joseph C. Turner), 419
Agricultural Education in Great Britain, 143
Agricultural Education : Post-War (Ronald Ede), 673
Agricultural Education (Post-War) : Report of the Committee on, 539
Agricultural Land : Drainage of (H. H. Nicholson), 144
Agricultural Research in Great Britain (Agricultural Research Council report on), 396
Agriculture in Devastated Europe : Restarting (Sir John Russell), 433
Agriculture and World Nutritional Needs (F. le Gros Clark), 274 ; (Prof. J. R. Marrack), 509
Agriculture (European) : Co-operative Systems in (British Association, Division for the Social and International Relations of Science, conference on), 418, 523
Agropyron repens, Beauv. : Nucleoli in (Dr. B. C. Sharman), 170
Aids (Visual) to Education, 637
Air we Breathe in Town and Country (Dr. G. M. B. Dobson), 165 ; (Dr. G. M. B. Dobson and Dr. A. R. Meetham), 324
Air Currents, Light, Humidity and Temperature on Slugs : Effect of (Mrs. Barbara H. Dainton), 25
Air Estimates in the House of Commons (Sir Archibald Sinclair), 360
Air Navigation (Lieut.-Comdr. P. V. H. Weems), British Empire edition, revised and edited by Arthur J. Hughes and P. F. Everitt, second edition, *review*, 572
Air Pollution of Leicester (Dr. A. R. Meetham), 165
Air Transport : Post-War (Viscount Cranborne), 360
  Post-War Commercial (F. C. R. Jaques), 247
Air Transport Command within the R.A.F. : Creation of an, 360
  Air Chief Marshal Sir F. W. Bowhill to be in charge of, 360
Air-Blast Circuit-Breakers (A. R. Blandford), 453
Aircraft (Wooden) for War Purposes, 17
Aircraft Establishment (Royal), Farnborough (E. Mardles), 562
Airman's Laboratory, The, *review*, 292
Airmen : Anoxæmic Changes in the Liver, with regard to the 'High-Altitude Death' of (Dr. Peter Ladewig), 558
Albert Gold Medal for 1943 of the Royal Society of Arts awarded to Sir John Russell, 611
Alchemy : Newton and, 417
Alcohol and Tuberculosis (Dr. Emil Bogen), 477
Aleutian Islands Archipelago : Earthquake on January 27, 530
Algæ : Comparative Morphology of the (F. E. Fritsch), 112
Algæ (Blue-Green) in Nitre Formation in Deserts : Role of (S. V. Odintzova), 701
Algæ (Marine) in Subantarctic and Antarctic Waters : Communities of (C. Skottsberg), 26
Alighting-Boards and Colour-Sense in Bees (Dr. Ruth Lotmar), 644
Allometry to the Study of English Senonian Echinocorys : An Application of the Principles of (Dr. John F. Hayward), 617
Alloys : Bibliography of the Literature relating to Constitutional Diagrams of (Compiled by Dr. J. L. Haughton), *review*, 600
Alloys (Silver) : Hardness of (J. H. Frye, jun., and W. Hume-Rothery), 57
Altitude : Effects of, 193
Altitude (Effects of) on the Chemical Composition of Cultivated Plants (S. O. Grebinsky), 338
America Faces the War (Archibald MacLeish), 147
America (North) : Atlas of the Scale Insects of (G. F. Ferris), Fourth Series, *review*, 657
  Prehistory of, 282
American Land and Freshwater Isopod Crustacea (William G. Van Name), 282
American Library in Great Britain, 612
American Scientists for the War : The Organization of (Pilgrim Trust Lecture of the Royal Society by Dr. Karl T. Compton), 362, 601
American Steam-Boat Pioneer, 76
American Troops Abroad : Health of, 529
American Unity : Problems of (T. Raymont), 677
American Work on the Ultracentrifuge, *review* by J. St. L. Philpot, 485
American (Anglo-) Union as a Nucleus of World Federation (Prof. George Catlin), 77
American (Latin) Culture : Great Britain and, 274
Amines (Aromatic) and Phenolic Substances : A New Method of Nuclear Methylation of (Miss M. G. Barclay, Dr. A. Burawoy and G. H. Thomson), 615
Amoeba lescherae (Dr. Monica Taylor and Catherine Hayes), 587
Amorphous (Colloidal and) Materials : Industrial Chemistry of (Prof. Warren K. Lewis, Lombard Squires and Dr. Geoffrey Broughton), *review* by Prof. F. G. Donnan, 289
Amphipoda : Occurrence of Crystals in the Skin of (D. M. Reid), 504
Amplifying and Recording Technique in Electro-Biology (G. Parr and W. Grey Walter), 330
Anæsthesia : Veterinary (Prof. J. G. Wright), 723
Analogy : Illustration by (W. R. Dunlop), 700
Analysis (X-Ray) : of Hæmoglobin (Joy Boyes-Watson and M. F. Perutz), 714
  in Industry (Institute of Physics conference on), 248, 506
Anatomy of Leguminous Root Nodules (Miss Helen L. Frazer), 141
Ancient Monuments of Cyrenaica and Tripoli (Prof. J. L. Myres), 381
Ancient World : North Syria as a Cultural Link in the (Sir Leonard Woolley), 144
Anglia (East) : New Palæolithic Industry from, 26
Anglo-American Union as a Nucleus of World Federation (Prof. George Catlin), 77
Anglo-Czechoslovak Chemical Collaboration, 667
Anglo-Egyptian Sudan : A Middle Pleistocene Discovery in the (G. Andrew and A. J. Arkell), 226
Animal Cell Growth Research : Charles L. Mayer Awards for, 19
Animal Disease in India : Climate and (Dr. F. C Minett), 733
Animal Life : The Changing Realms of (Charles Elton), 529
Animals in England : Industrial Fluorosis of (F. Blakemore), 30
Animals (Farm) : 'Teart' of Somerset, a Molybdenosis of (W. S. Ferguson), 30
Animals (Laboratory) : Welfare of (Universities Federation for Animal Welfare), 723
Animals (Plants and : Significance of Trace Elements in relation to Diseases of (Dr. H. H. Green), 28
Anoxæmia : Liver Vacuoles and (Dr. O. A. Trowell), 730
Anoxæmic Changes in the Liver, with regard to the 'High-Altitude Death' of Airmen (Dr. Peter Ladewig), 558
Answer (Question and) : The Logic of (Prof. A. D. Ritchie), 498
Antarctic Research, 647
Antarctic Surface Waters : Phytoplankton Periodicity in (T. John Hart), 647
Antarctic (Subantarctic and) Waters : Communities of Marine Algæ in (C. Skottsberg), 26
Anthracene in Presence of Naphthacene : Fluorescence of (S. C. Ganguly), 673
Anthropological Studies : Portuguese, 300
Anthropologist Looks at the United States : An, *review* by Prof. H. F. Fleure, 405
Anti-Locust Campaign : An International (Dr. B. P. Uvarov), 41
Antimony Content and Toxicity of Urea Stibamine (R. C. Guha, N. K. Dutta and Dr. B. Mukerji), 108
Anti-Social Behaviour Disorders : The Differentiation, Prevention and Treatment of (Dr. Norwood East), 9
Antithyroid Substance (Natural) : Paraxanthine as a (Dr. G. S. Carter, Dr. F. G. Mann, J. Harley-Mason and G. N. Jenkins), 728
Aphids : Wing Development in (A. F. Shull), 477
Apologetic, Old and New, *review* by the Rev. J. C. Hardwick, 710
Appendix of the Rabbit : Phagocytosis in the (Frank Baker and John Enticknap), 532
Apple : Newton and the (Prof. E. N. da C. Andrade), 84
Apple Leaves : Effects of Leafhopper Feeding Injury on Apparent Photosynthesis and Transpiration of (G. E. Marshall, N. F. Childers and H. W. Brody), 477
Applications of Elementary Mathematics, *review* by Dr. W. G. Bickley, 626
Applied Electricity (A. W. Hirst), *review* by Dr. L. E. C. Hughes, 713
Applied Photography (Prof. J. Yule Bogue), 718
Appreciation (Public) of Science (H. Brewer), 534
Aqueous Solutions : Mode of Action of Ionizing Radiations on (Dr. W. M. Dale, W. J. Meredith and M. C. K. Tweedie), 280
Aqueous Urea Solution : Long-Chain Molecules in (Dr. R. E. D. Clark), 642
Arabia Felix, *review* by Miss G. Caton-Thompson, 375
Arc (Coloured) in the Sky (Miss F. E. Penrose), 300
Archæological Finds in the Scottish South West Isles (J. Harrison Maxwell), 282

Archæological and Geological Investigations in the San Jon District, Eastern New Mexico (F. H. Roberts), 282
Archæologists (British) in Greece, *review* by Prof. John L. Myres, 65
Archæology and Modern Man, *review* by M. C. Burkitt, 515
Archæology (Prehistoric) of North-West Africa (Frederick R. Wulsin), *review* by M. C. Burkitt, 36
Architecture (Naval) : Scholarships in (Institution of Naval Architects), 20
Arctic : The 'Friendly', *review* by Squadron-Leader J. N. L. Baker, 264
Arctic Plants : Early Collections of (Dr. N. Polunin), 645
Argentina : Committee on the Effects of Altitude, 193
  Medical Services in (Dr. Hugo J. D'Amato), 135
Aristotle, Newton, Einstein (Prof. E. T. Whittaker), 59
Army (British) : Education in the (Lieut. T. H. Hawkins), 438
Army Medicine : Progress of, *review* by Major J. Marshall, 627
Army Nature Observation Scheme, 668
Aromatic Amines and Phenolic Substances : A New Method of Nuclear Methylation of (Miss M. G. Barclay, Dr. A. Burawoy and G. H. Thomson), 615
Arsonium Salt : An Optically Active (Dr. F. G. Mann and F. G. Holliman), 474
Art : Science in the Service of, 133
Artificial Insemination Centres for Dairy Cows (Dr. S. Bartlett and Dr. J. Edwards), 114
Artificially Dried Grass : Production of (J. McNair and A. B. Fowler), 529
Artists' Materials and Methods, *review* by F. Ian G. Rawlins, 262
Ascorbic Acid in Dehydrated Vegetables : Stability of (Dr. W. R. Aykroyd), 22
Ascorbic Acid in Mashed Potatoes (G. N. Jenkins), 473
Ascorbic Acid in Metaphosphoric Acid Extracts : Stability of (L. W. Mapson and C. A. Mawson), 222
Ascorbic Acid in Tea : Oxidation of (G. A. Snow and S. S. Zilva), 112
Aspects of International Collaboration, 679
Astasia Harrisii : Golgi Apparatus in (J. D. Smyth), 110
Astrographic Zone (Greenwich) : Obscured Regions in the (E. G. Martin), 27
Astronomical Data : Spanish, *review*, 405
Astronomical Thought : Copernicus and his Influence on, 583
Astronomy : Evolution in (Sir James Jeans), 7
  Foundations of (Prof. W. M. Smart), *review* by Dr. J. C. P. Miller, 38
Astronomy without a Telescope : First Steps in (P. F. Burns), *review*, 151
Asymmetric Transformations (Dr. M. M. Jamison and Prof. E. E. Turner), 391
Ataxia (Enzootic) or 'Swayback' of Lambs in England in relation to Copper Feeding of Ewes during Pregnancy (Prof. T. Dalling), 29
Athens : The Annual of the British School at, No. 38 : Session 1937–38 ; No. 39 : Session 1938–39, *review* by Prof. John L. Myres, 65
Atkinson Memorial Lecture on Industrial Research in Great Britain, a Policy for the Future (Dr. P. Dunsheath), 259
Atlantic (mid-north-) : Earthquake on December 31, 362
Atlantic Charter : World Waste and the (Sir James Marchant), 554
Atlantis Revisited, *review* by R. Brightman, 121
Atlas of the Scale Insects of North America (G. F. Ferris), Fourth Series, *review*, 657
Atmospheric Pollen : A Census of (H. A. Hyde and Dr. D. A. Williams), 82
Atmospheric Pollution (Dr. G. M. B. Dobson and Dr. A. R. Meetham), 324
Atomic Photography : Towards (C. W. Bunn), 506
Atoms : Order and Chaos in the World of (B. C. Saunders and R. E. D. Clark), *review* by Prof. John Read, 488
Attitudes (Mental) in Time of War (British Psychological Society symposium on), 684
Australasia : Cobalt and other Trace Elements in relation to Disease in (Sir Charles Martin), 29
Australasian Antarctic Expedition of 1911–14, Scientific Reports, Series A, Vol. 1, 500
Australia : New Farm Crops for (A. McTaggart and T. B. Paltridge), 445
Authoritarianism versus Individuality, *review* by Dr. H. G. Baynes, 597
Automatic Protection of A.C. Circuits (G. W. Stubbings), third edition, revised, *review* by Dr. L. E. C. Hughes, 683
Autonomic Leaf Movements and Water-Balance in the Plant (C. V. Krishna Iyengar), 645
Auxin Production during Development of the Grain in Cereals (Dr. E. S. J. Hatcher), 278
Avalanche Research in Switzerland, 528
Avebury : Acquisition by the National Trust, 387
Avian Phylogeny (Percy R. Lowe), 112
Aviation (Post-War Civil) in Great Britain, 175
Azeotropic Mixtures (Ternary) : Determination of the Water Content of Wood and other Substances by means of (Dr. W. R. G. Atkins), 449
Axis Oppression of Education (Inter-Allied Information Committee report on), 148
Azolla intertrappea Sahni and H. S. Rao (Indian Silicified Plants, I), (B. Sahni), 338

BACTERIA (Flocculation of) by Protozoa (Garrett Hardin), 642
Badger in Britain, 499
Bakerian Lecture of the Royal Society (Prof. R. V. Southwell), 723
Balance (Polygenic) in the Canalization of Development (Dr. K. Mather), 68
Banana Leaf Spot Disease : Soil Conditions affecting Production of Perithecia in (R. Leach), 199
Barley : A Grain-Borne Disease of, 369
Barley and *Helminthosporium sativum* P., K. and B. : Host-Parasite Relationships of (H. W. Mead), 369
Barley (Wheat and) : Eye-Spot of (Miss Mary D. Glynne), 142
Barometer : Tercentenary of the invention of the, 695
Base Exchange : Demonstrations of (S. Mattson), 702
Basic Substances (Acid or) in Damaged Fabrics : Detection of (Dr. C. Whitworth and D. W. Poxon), 198
Basis (The Individualist) of International Law and Morals (Prof. Morris Ginsberg), 648
Basis of Scientific Planning (Prof. H. Levy), 157
Bausch and Lomb Artificial Star Projector (James R. Benford), 192
Beads (Middle-Piece) in the Cavia Spermatozoon (Prof. J. Brontë Gatenby and L. Collery), 253
Beak Marks on Butterflies of Different Edibility to Birds : The Relative Frequency of (Prof. G. D. H. Carpenter), 173
Bed-Bug, its Habits and Life-History (A. W. McKenny Hughes and C. G. Johnson), fifth edition, 106
Bees : Alighting-Boards and Colour-Sense in (Dr. Ruth Lotmar), 644
Behaviour of Birds, *review* by B. W. Tucker, 542
Behaviour of Rubber in Elongation, Compression and Shear (Dr. L. R. G. Treloar), 563
Behaviour of Thiuram Sulphides, etc., in Spore Germination Tests (H. B. S. Montgomery and Dr. H. Shaw), 333
Behaviour (Instinctive) : The Stereotypy of (Dr. E. S. Russell), 612
Behaviour Disorders (Anti-Social) : The Differentiation, Prevention and Treatment of (Dr. Norwood East), 9
Behind the Urals, an American Worker in Russia's City of Steel (John Scott), *review* by Dr. David Williams, 516
Bengal : Sylvicultural Research in (D. A. G. Davidson), 135
Bevel Protractor : A New Universal (E. R. Watts and Son, Ltd.), 78
Beveridge Report : Minimum Human Requirements and the (Sir Joseph Barcroft, Prof. Stanley Davidson, Sir F. Gowland Hopkins, Lord Horder, Prof. Julian Huxley, Prof. J. M. Mackintosh, Sir Charles Martin, Sir Robert McCarrison, Lord Moran of Manton, B. S. Rowntree, Prof. J. C. Spence and Prof. W. H. Wynn), 422
Bhuj : Earthquake on October 31, 136
Bibliography of the Literature relating to Constitutional Diagrams of Alloys (Compiled by Dr. J. L. Haughton), *review*, 600
Bibliography on Management and Labour (Sheffield City Libraries Research Bulletin No. 7), 557
Bigsby Medal of the Geological Society awarded to Dr. G. M. Lees, 164
Biochemistry and Chemotherapy (Henry McIlwain), 270
Biochemistry and Morphogenesis (Dr. Joseph Needham), *review* by Sir Joseph Barcroft, 402
Biogeochemical Research in the U.S.S.R. (A. P. Vinogradov), 659
Biological Action of Vitamin K and its Synthetic Analogues : Mechanism of (Prof. M. M. Shemiakin, L. A. Schukina and J. B. Shvezov), 585
Biological Fluids : Determination of the Osmotic Pressure of (Dr. R. Aschaffenburg), 169
Biological Science in Russia : Development of (Ch. S. Koshtoyants), 408
Biological Statistics, *review*, 319
Biological Systems : Linkage of Physico-Chemical Processes in (Prof. E. J. Conway and E. O'Malley), 252
Biology : Statistical Analysis in (Dr. K. Mather), *review* by Prof. J. B. S. Haldane, 654
Biology of the Brown Trout, 26
Biology (The New) : Molecular Films, the Cyclotron and (Hugh Stott Taylor, Ernest O. Lawrence and Irving Langmuir), *review* by Prof. J. A. Crowther, 67
Biology (Social) in relation to Human Life and Culture: Vacation School on (British Social Hygiene Council), 389
Biology Staining Schedules for First Year Students (R. R. Fowell), *review* by Prof. R. C. McLean, 572
Biology and Health : Summer School in (Central Council for Health Education), 388, 499
Biology and Health Education (Central Council for Health Education conference on), 498
Biometry : Modern, *review* by Prof. J. B. S. Haldane, 654
Bird Display (Edward A. Armstrong), *review* by B. W. Tucker, 542
Birds : The Behaviour of, *review* by B. W. Tucker, 542
  The Relative Frequency of Beak Marks on Butterflies of Different Edibility to (Prof. G. D. H. Carpenter), 173
Birds of Britain (James Fisher), *review*, 122
Birds of the British List wintering in West Africa (A. C. Allnutt), 20
Birds of Lakeland (Carlisle Natural History Society), 51
Birds of the Sevenoaks or Western District of Kent : A Handlist of the (James M. Harrison), *review*, 151
Birds, British: *review*, 122
  Autumn Sexual Behaviour and the Resident Habit of many (Dr. W. S. Bullough), 531
Birds (Wild) and Home-Grown Food in Britain (Dr. Walter E. Collinge), 128
Birds (Wild) eating Butterflies and the Preferences Shown : Observations and Experiments in Africa by the late C. F. M. Swynnerton on (Prof. G. D. H. Carpenter), 173
Birds and Butterflies (Dr. C. B. Williams), 173
Biringuccio in English, *review* by Prof. John Read, 569
Birmingham Medal of the Institution of Gas Engineers awarded to Dr. E. W. Smith, 695
Birmingham and the West Midlands : Reconstruction in (Councillor Paul Cadbury), 667
Blood Cells (Red) : Mechanism of Lysis of (Lt.-Col. Brian Maegraith, Brig. G. M. Findlay and Major N. H. Martin), 252
Blood Group Determination : Medico-Legal (Dr. David Harley), *review* by Dr. H. S. Holden, 487
Blood-Group Frequencies : A Sex Difference in (Prof. R. A. Fisher and J. A. Fraser Roberts), 640
Blood Grouping and its Medico-Legal Significance, *review* by Dr. H. S. Holden, 487
Blue-Green Algæ in Nitre Formation in Deserts : Role of (S. V. Odintzova), 701
Body as a Guide to Politics (Dr. W. B. Cannon), 77
Bogotá : Murine Typhus in (Dr. Luis Patino-Camargo), 445
Boiler-House Measurements and Control (G. H. Barker and A. L. Hancock), 220
Bolgary (Velikie) : Excavations at (Prof. Alexey Smirnov), 300
Bolivia and Western Matto Grosso : Natives of (Alfred Métraux), 701
Bombed Areas : The Flora of (Prof. E. J. Salisbury), 462
Bones and Muscles : Influence of a Prolonged Partial Deficiency of Vitamin C on the Recovery of Guinea Pigs from Injury to (Dr. E. Kodicek and Dr. P. D. F. Murray), 395
Books : Recent Scientific and Technical, Supp. iii, January 30 ; Supp. ii, February 27 ; Supp. ii, March 27 ; Supp. ii, April 24 ; Supp. ii, May 29 ; Supp. ii, June 26
Books (Foreign) and Translations, 275
Bored Stones of South Africa (A. J. H. Goodwin), 26
Boron Trifluoride : Systems with (H. S. Booth and D. R. Martin), 113
Botanic Garden, Oxford : History of the, 367
Botany : Some Early Czech Contributions to (Dr. Gerald Druce), 98
Botany in India (Sir Geoffrey Evans), 580
Bothriolepis : Fishes of the Genus (Walter Gross), 56
Bottle Feeding : Breast and, 687
Boulder (Great Iron) from Ovifak (H. Löfquist and C. Benedicks), 26

Boundaries (Regional) in Great Britain (Association for Planning and Regional Reconstruction), 584
Boyle's Original Observations on the Pressure and Volume of a Gas : Accuracy of (Dr. R. C. Geary), 476
Bracken-land : Reclamation of (Dr. Maurice Copisarow), 139
Brackish Water : Newt Larvæ in (Helen Spurway), 109 ; (Eric Hardy), 226
Brazilian Foods : Vitamin Content of (Dr. Moura Campos), 584
Bread : 'White' (Dr. A. M. Maiden), 336
Bread (Flour and) : National, Third Report, 629
Breast and Bottle Feeding, 687
Bristol : The Population of (H. A. Shannon and E. Grebenik), *review* by D. Caradog Jones, 514
Britain : The Badger in, 499
  The Birds of (James Fisher), *review*, 122
  Chinese Students for, 639
  A Diatom New to (Frederick Burke and John R. Carter), 672
  Nature Conservation in (Memorandum No. 3 of the Conference on Nature Preservation in Post-War Reconstruction), 707
  Planning Post-War, 311
  Sheep 'Pining' in (W. Lyle Stewart), 29
  A Swedish View of, *review* by J. G. Crowther, 656
  Venereal Disease in (Sydney M. Laird), *review*, 683
  Wild Birds and Home-Grown Food in (Dr. Walter E. Collinge), 128
  see also under Great Britain
Britain and her Dependencies (Lord Hailey), 399
British Archæologists in Greece, *review* by Prof. John L. Myres, 65
British Army : Education in the (Lieut. T. H. Hawkins), 438
British Birds, *review*, 122
British Birds : Autumn Sexual Behaviour and the Resident Habit of many (Dr. W. S. Bullough), 531
British Colonial Empire : Freshwater Fisheries in the (Dr. E. B. Worthington), 353
British Commonwealth Affairs : Survey of (Prof. W. K. Hancock), 399
British Democracy : A Comment on (Sir Hector Hetherington), *review* by R. Brightman, 543
British Empire : Colonial Development in the, 315
  Colonial Research in the (Dr. Lucy Mair), 87
British Empire Cancer Campaign : Nineteenth Annual Report of the (Dr. E. Boyland), 451
British Empire Timbers : Some, 732
British Ideals : The Temper of (Prof. John Laird), *review* by R. Brightman, 543
British Isles : Exotic Woodlice in the (Dr. Walter E. Collinge), 394
British Lepidoptera : Distribution and Origin of (B. P. Beirne), 701
British Mammals in War-time, 247
British Medicine and the Vienna School (Dr. Max Neuburger), *review* by Dr. J. D. Rolleston, 461
British Method of Government (A. K. White), *review* by R. Brightman, 543
British Political Institutions (Prof. Andrew Browning), *review* by R. Brightman, 543
British Sources of Specialized Information : War-time Guides to, No. 4, 77
British Species of Ephemeroptera or Mayflies : Keys to the (D. E. Kimmins), 112
British Trade Unionism (Dr. J. Kuczynski), 446
British Tradition, The, *review* by R. Brightman, 543
British Way, The, Nos. 1–5, *review* by R. Brightman, 543
British Way in World Trade (Dr. Alec L. Macfie), *review* by R. Brightman, 543
British and Viennese Medical Schools, *review* by Dr. J. D. Rolleston, 461
Broadcasting (Shore-Wave) : Ten Years Technical Progress (Sir Noel Ashbridge), 17
Browne (Buckston) Prize Essay for 1943–44 (Harveian Society of London), 221
Buenos Aires, Academia Nacional de Medicina : Establishment of the Hirsch Medical Scholarship Fund, 557
Bug, The Bed- : its Habits and Life-History (A. W. McKenny Hughes and C. G. Johnson), fifth edition, 106
Building Industry : Relation of Technical Education to the, 427
  White Paper on Training for the, 427
Burma (India and) : Systematic and Taxonomic Studies on the Flora of (Dr. Kalipada Biswas), 580
Burton (Montague) Lecture on International Relations (J. G. Winant), 554
Butterflies of Different Edibility to Birds : The Relative Frequency of Beak Marks on (Prof. G. D. H. Carpenter), 173
Butterflies and the Preferences Shown : Observations and Experiments in Africa by the late C. F. M. Swynnerton on Wild Birds eating (Prof. G. D. H. Carpenter), 173
Butterflies : Birds and (Dr. C. B. Williams), 173

C. *diphtheriae* and *L. casei* : Nutritional Requirements of (F. W. Chattaway, Dr. F. C. Happold and M. Sandford), 559 ; (Dr. B. Lythgoe and Prof. A. R. Todd), 559
Cable : The High-pressure Gas-filled (C. J. Beaver and E. L. Davey), 669
Cables of a Single-Phase System : Eddy Current Losses in Single-Conductor Paper-Insulated Lead-Covered Unarmoured (Dr. A. H. M. Arnold), 88
Cables (Submarine) : Joints in (R. Miller and C. T. Rose), 248
Cables (Telephone) : Measurement of Lightning in relation to (J. J. Mahoney, jun.), 537
Caddo Indians : History and Ethnology of the (John R. Swanton), 644
Calcium Carbonate (Creta Præparata) in National Flour : Estimation of Added (E. N. Greer, J. D. Mounfield and W. J. S. Pringle), 27
Calcium Metabolism and Nutrition Problems (Dr. J. D. Robertson), 379
Californian Sequoias (Looby and Doyle), 142
Callendar (H. L.) and the Theory of the Liquid State (Dr. R. S. Silver), 583
Calomel Cell for *p*H Measurements : A Modified (A. D. Elmsly Lauchlan and Dr. James E. Page), 84
Canada : Science and Reconstruction in (Prof. J. K. Robertson), 444
Canadian Services : King's Birthday Honours for, 666
Canalization of Development : Polygenic Balance in the (Dr. K. Mather), 68
Cancer : Research on, 445
Cancer Campaign (British Empire) : Nineteenth Annual Report of the (Dr. E. Boyland), 451
Cancer Control in the United States (Dr. A. Scheele), 668
Cancer Research : Mythology of (Prof. E. L. Kennaway), 302
Cape of Good Hope : Report of the Royal Observatory for 1941, 78
Carty Medal for 1943 of the U.S. National Academy of Sciences awarded to Prof. Edwin Grant Conklin, 722
Cat (Dog and) : A Nuclear Ring in the Developing Male Germ Cells of (I. Zlotnik), 670
Cattle : Sex Ratio in (J. W. Gowen), 56
Cauliflory : A Modern Study of, 481
Cavia Spermatozoon : Middle-Piece Beads in the (Prof. J. Brontë Gatenby and L. Collery), 253
Cell for *p*H Measurements : A Modified Calomel (A. D. Elmsly Lauchlan and Dr. James E. Page), 84
Cell Growth (Animal) Research : Charles L. Mayer Awards for, 19
Cells (Injured) : Proliferation-promoting Substances from (J. R. Loofbourow), 141
Cells (Malignant Tumour) : Origin of (Dr. P. C. Koller), 244
Census of Atmospheric Pollen (H. A. Hyde and Dr. D. A. Williams), 82
Centenaries (Scientific) in 1943 (Eng.-Capt. Edgar C. Smith), 15
Centenary : of the House of Macmillan, 231
  of the Royal Dockyard Schools, 388
Centrifuge : American Work on the, *review* by J. St. L. Philpot, 495
Century of Progress—Men, Manners, Inventions (Dr. E. F. Armstrong), 257
Cereal Seed : Disinfection of, 194
Cereals : Auxin Production during Development of the Grain in (Dr. E. S. J. Hatcher), 278
Chadwick Lecture on the Differentiation, Prevention and Treatment of Anti-Social Behaviour Disorders (Dr. Norwood East), 9
Chance, Freewill, and Necessity in the Scientific Conception of the Universe (Prof. E. T. Whittaker), 612
Chaos (Order and) in the World of Atoms (B. C. Saunders and R. E. D. Clark), *review* by Prof. John Read, 433
Characteristics (Soil) : Human Activities and (Dr. F. E. Kenchington), 83
Chemical Action of X-Rays on a Non-Aqueous Solution : Mode of (Dr. E. Broda), 448 ; *erratum*, 530
Chemical Analysis (Qualitative) of Inorganic Substances : A Course of Instruction in the (Prof. Arthur A. Noyes), tenth edition, revised and rewritten by Prof. Ernest H. Swift, *review*, 657
Chemical Attack upon Pests (Dr. R. E. Slade), 649
Chemical Background of Growth, *review* by Sir Joseph Barcroft, 402
Chemical Collaboration : Anglo-Czechoslovak, 667
Chemical Composition of Cultivated Plants : Effects of Altitude on the (S. O. Grebinsky), 338
Chemical Equilibria (Quantum Statistics,) and Reaction Kinetics, *review* by Dr. C. H. Bamford, 320
Chemical Industry in Europe, 50
Chemical Kinetics of Organic Reactions in Liquid Systems : Mechanism and (General Discussion held by the Faraday Society), *review*, 516
Chemical Kinetics in the Soviet Union : Advances of (Nikolai Semenov), 185
Chemical (Organic) Methods : Recent Advances in (Dr. E. R. H. Jones), 564
Chemical Reactivity : Resonance and (Prof. M. Polanyi), 96
Chemical Warfare : Precautions against, *review*, 404
Chemical and Mineral Products : Control of, 455 ; (Sir Robert Robinson), 562
Chemical and Physical Properties of Luminescent Materials (Dr. J. W. Strange), 73
Chemistry for 1941 : Annual Reports on the Progress of, Vol 38, *review*, 95
Chemistry (Applied) : Reports of the Progress of, Vol. 26, 1941, *review*, 95
Chemistry (Industrial) of Colloidal and Amorphous Materials (Prof. Warren K. Lewis, Lombard Squires and Dr. Geoffrey Broughton), *review* by Prof. F. G. Donnan, 289
Chemists in Great Britain, 191
Chemotherapy : Biochemistry and (Henry McIlwain), 270
Child Welfare (Maternal and) in Venezuela (Dr. Pastor Oropeza), 221
Children (School) in South Africa : Physical Fitness of (Prof. D. Burns), 704
Children's Diseases : Folk-Lore of (Dr. J. D. Rolleston), 193
Chile : Earthquake on April 6, 669
  Public Health in, 135 ; (Dr. Juan Antonio Rios), 668
China : Great Britain and (Sir John Pratt), 77
Chinese Men of Science : Message from, 612
Chinese Plants to Great Britain : Introduction of, 136
Chinese Students for Britain, 639
Chlorine (A Light Effect in) under Electric Discharge : Influence of the Intensity and Frequency (Prof. S. S. Joshi and P. G. Deo), 561
Chlorine Hydrate : Composition of (Dr. Ivan Harris), 309
Chree (Charles) Medal and Prize for 1943 awarded by the Physical Society to Prof. B. F. J. Schonland, 218
Christianity and Truth : Science (Rev. Canon A. E. Baker), *review* by the Rev. J. C. Hardwick, 710
Cicer arietinum : Mutations in (R. B. Ekbote), 233
Circuit-Breakers : Air-Blast (A. R. Blandford), 453
Citizen : Science and the (British Association, Division for the Social and International Relations of Science, conference on), 191, 382, 595, 607
Citizen Responsibilities : Education for (John M. Clark, Lloyd Allen Cook and Stuart A. Queen, Frank D. Graham, Richard Hartshorne, William Ernest Hocking, Roy F. Nichols and Arthur C. Bining, Frederic A. Ogg, Ernest Minor Patterson, Calvin P. Stone, Griffith Taylor, Wilson D. Wallis), 483
Citizenship : Education for, 433
Civil Servants : Training of, 361, 511
  R. Assheton appointed chairman of a committee to consider the, 361
Civilian Contribution to Education in H.M. Forces, 648
Classification of Rheological Properties (Dr. R. Bartlett), 198
Classification (Natural) of the Steroids : An Attempt at a (Prof. Hans Selye), 662
Clearing Derelict Land : Methods of, 78
Climate and Animal Disease in India (Dr. F. C. Minett), 733
Climate and the Energy of Nations (S. F. Markham), *review* by Prof. H. J. Fleure, 431
Clostridia of Gas Gangrene : Identification of (Dr. G. F. Petrie and D. Steabben), 644
Clough Memorial Fund of the Edinburgh Geological Society : Grants for 1943–1944, 79
Clough Memorial Medal of the Edinburgh Geological Society for 1941–1942 presented to Mr. James L. Begg, 79
Cloves : Medico-Dental History of (Dr. Eugene J. Molnar), 194
Club-Root Fungus : Control of the (D. E. Green), 701
Co-Enzymatic Reactions (Prof. J. K. Parnas), 577

Coal : Microscope Observations of the Crushing of (Dr. R. G. H. B. Boddy), 54
Coal as the Basis of the War Effort, 723
Coal Conservation in Great Britain, 61
Coal Science and Technology, *review* by Dr. J. G. King, 432
Coal Utilization Research and the National Economy, 709
Coals : Coke Formation Process and Physico-Chemical Properties of (Prof. W. Swietoslawski), *review* by Dr. J. G. King, 432
  Optical Dispersion for (C. G. Cannon and Dr. W. H. George), 225
  Refractive Index of (C. G. Cannon and Dr. W. H. George), 53
Coals and Cokes : The Ultra-fine Structure of (British Coal Utilization Research Association conference on), 613
Coastal Radio Telephone (H. M. Pruden), 732
Cobalt and other Trace Elements in relation to Disease in Australasia (Sir Charles Martin), 29
Coke Formation Process and Physico-Chemical Properties of Coals (Prof. W. Swietoslawski), *review* by Dr. J. G. King, 432
Cokes (Coals and) : The Ultra-fine Structure of (British Coal Utilization Research Association conference on), 613
Cold : Deaths from Exposure to, 695
Cold Work in Metals : X-Ray Evidence of the Nature of (A. R. Stokes, K. J. Pascoe and Dr. H. Lipson), 137
Coleoptera (Adult and Immature) : the Musculature of the Labrum Labium and Pharyngeal Region of (C. K. Dorsey), 644
Collaboration (International) : Aspects of, 679
Colloid Science : Advances in (edited by Dr. Elmer O. Kraemer, in collaboration with Prof. Floyd E. Bartell and Dr. S. S. Kistler), Vol. 1, *review* by Prof. H. W. Melville, 5
Colloidal Electrolytes : Freezing-Points of Solutions of Typical (S. A. Johnston and Prof. J. W. McBain), 478
Colloidal and Amorphous Materials : Industrial Chemistry of (Prof. Warren K. Lewis, Lombard Squires and Dr. Geoffrey Broughton), *review* by Prof. F. G. Donnan, 289
Colombia : Earthquake on December 26, 669
Colonial Administration : Farm and Forest in, 652
Colonial Dependencies : Development of, 399
Colonial Development in the British Empire, 315
Colonial Development and Welfare Act of 1940 : Statement of Policy on, 315
  Report on the operation of the, 399
Colonial Empire (British) : Freshwater Fisheries in the (Dr. E. B. Worthington), 353
Colonial Policy, 219
Colonial Research in the British Empire (Dr. Lucy Mair), 87
Colonial Service : Appointments and promotions, 20, 165, 362, 557, 584
Colonial Territories : Evolution of, 360
Colonies : Education and the (Prof. A. V. Hill), 360
  Social Welfare in the, 275
Colour : Luminescence and, 73
Colour Perception : A Physiological Theory of (Prof. Ragnar Granit), 11
Colour Printing : The Use of Fluorescent Pigments in (F. W. Coppin), 73
Colour-Sense in Bees : Alighting-Boards and (Dr. Ruth Lotmar), 644
Colour Temperature of Convective Stars (W. S. Tai and A. D. Thackeray), 478
Colour Vision : Physiology of (E. N. Willmer), 213, 632 ; (Dr. F. W. Edridge-Green), 422 ; (Prof. H. Hartridge), 422 ; (K. J. W. Craik), 727
Colouring Matter (Synthetic) : Tetra-Arylazadipyrromethines, a New Class of (Dr. M. A. T. Rogers), 504
Combustion of Hydrocarbon Mixtures : Influence of Water Vapour upon the (Prof. W. T. David and J. Mann), 392
Comet Oterma (1942*f*) : Orbit computed by Dr. F. L. Whipple, 362
Comet Whipple (1942*g*), 51, 362
  A New Orbit computed by Dr. M. Davidson, 106
Comet Whipple-Fedtke : Ephemeris for June, 613
Commercially Useful Fluorescent Substances (H. G. Jenkins), 73
Common Sense and Decency : Science (Dr. Irving Langmuir), 266 ; (Adam Gowans Whyte), 450 ; (A. J. Bateman), 450 ; (William P. D. Wightman), 589 ; (E. Denne), 589
Commonwealth Affairs (British) : Survey of (Prof. W. K. Hancock), 399
Communal Feeding : Problems of, 134
  Soviet Forms in (F. le Gros Clark), 134
Compression-Ignition Engines : High-Speed, *review* by Prof. S. J. Davies, 40
Concept of Energy (Dr. A. E. Bell), 519
Concept of Polygenes (A. C. Fabergé), 643
'Condensation' in Fermi-Dirac Statistics (Prof. D. S. Kothari and Brij Nath), 420
Condensation in High-Velocity Steam : Electrical Detector of (A. M. Binnie and J. R. Green), 283
Configuration of Purine Nucleosides (Prof. J. M. Gulland, G. R. Barker and D. O. Jordan), 109
Conical Refraction (Sidney Melmore), 620
Conservation of Scientific and Technical Periodicals, 512
Conservation (Coal) in Great Britain, 61
Constitutional Diagrams of Alloys : Bibliography of the Literature relating to (Compiled by Dr. J. L. Haughton), *review*, 600
Consumption and Rationing : War-time (League of Nations Publication 1942, II, A.2), 371
Containers : Plywood, 731
  Rectangular Plywood, 732
Continuation School : Future of the, 567
Control : Electric Power System (H. P. Young), *review*, 349
Control of Chemical and Mineral Products, 455 ; (Sir Robert Robinson), 562
Control of the Club-Root Fungus (D. E. Green), 701
Control of Injurious Insects : Place of Research in the (Prof. J. W. Munro), 157
Control of Raw Materials, 452
Cooper Committee : Report on Hydro-electric Development in Scotland, 177, 187
Co-operation in Research, 300
Co-operation : International, 157
Co-operative Systems in European Agriculture (British Association, Division for the Social and International Relations of Science, conference on), 418, 523
Coopers Hill War Memorial Prize and Medal : Triennial award for 1943, 276
Copernicus and the Heliocentric Theory (Dr. H. Spencer Jones), 573
Copernicus and his Influence on Astronomical Thought, 583
Copernicus Commemoration, 611
Copper (Metallic) : Control of Potato Blight (*Phytophthora infestans*) by Spraying with Suspensions of (E. C. Large), 80
Copper, Zinc and other Trace Elements in relation to Physiological Function and Enzyme Systems (Dr. H. Mann and Prof. D. Keilin), 28
Copper Feeding of Ewes during Pregnancy : Enzootic Ataxia or 'Swayback' of Lambs in England in relation to (Prof. T. Dalling), 29
Cords, Surface Condition and Quality of Glassware, 106
Cosmic Rays : An Exceptional Increase of (Prof. A. Duperier), 308
  Origin of (Dr. R. A. Millikan, Dr. H. V. Neher and Dr. W. H. Pickering), 663
Cotton Immune from Natural Crossing : Breeding of a (Dr. S. C. Harland), 307
Council of Europe : Reconstruction and a (Winston Churchill), 359
Counteracting Sulphonamide Inhibitors (Dr. W. K. S. Wallersteiner), 586
Counting (Electrical) : with Special Reference to Counting Alpha and Beta Particles (Dr. W. B. Lewis), *review* by Dr. L. Jánossy, 377
Country (Town and) : The Air we Breathe in (Dr. G. M. B. Dobson), 165 ; (Dr. G. M. B. Dobson and Dr. A. R. Meetham), 324
Country Ways (Esther Meynell), *review* by Dr. E. W. Russell, 37
Countryside As It Was, *review* by Dr. E. W. Russell, 37 ; (H. J. Massingham), 254 ; (Dr. E. W. Russell), 254
Cows (Dairy) : Artificial Insemination Centres for (Dr. S. Bartlett and Dr. J. Edwards), 114
Crabs and Lobsters : Density of (A. G. Lowndes), 336
Crack Detection in Non-Ferrous Metals, 555
Crack-Detection : Magnetic (G. B. Young), *review*, 378
Crania (Human) in the United States National Museum Collections, Eskimo in General : Catalog of (Dr. Aleš Hrdlička), 59
Craniology : Eskimo (Dr. G. M. Morant), 59
Crayfishes of Florida (Horton H. Hobbs, jun.), 337
Crepis : Evolutionary Processes in (E. G. Babcock, G. L. Stebbins and J. H. Jenkins), 701
Crime : Juvenile, *review* by Prof. Cyril Burt, 291
Crop Failures (W. Morley Davies), 114
Crossing (Natural) : Breeding of a Cotton Immune from (Dr. S. C. Harland), 307
Crushing of Coal : Microscope Observations of the (Dr. R. G. H. B. Boddy), 54
Crustacea : Giant Fibres in, 282
  Unique Freshwater, 141
Crustacea (Isopod) : American Land and Freshwater (William G. Van Name), 282
Crustacean Muscles : Innervation of (William Holmes), 531
Crystal Photography with Divergent X-Rays (Dr. K. Lonsdale), 52
Crystal Structure of Graphite (Dr. H. Lipson and A. R. Stokes), 27
Crystal Structure of Phosphorus Pentachloride, 27
Crystallography (X-Ray) : Future Developments in (Prof. J. D. Bernal), 248
Crystals : Dynamics of Real (Dr. N. S. Nagendra Nath), 196
Crystals in the Skin of Amphipoda : Occurrence of (D. M. Reid), 504
Cubic Surfaces : The Non-Singular (B. Segre), *review* by Dr. H. F. Baker, 39
Cultivation of the Douglas Fir in Great Britain (Alexander L. Howard), 492 ; *erratum*, 557
Cultural Link in the Ancient World : North Syria as a (Sir Leonard Woolley), 144
Current Losses (Eddy) in Single-Conductor Paper-Insulated Lead-Covered Unarmoured Cables of a Single-Phase System (Dr. A. H. M. Arnold), 88
Currents (Lightning) : Magnitudes of (R. H. Golde), 421
Curtis C.76 Aircraft, 17
Cyclotron and the New Biology : Molecular Films, the (Hugh Stott Taylor, Ernest O. Lawrence and Irving Langmuir), *review* by Prof. J. A. Crowther, 67
Cygni (Visual Double Star 61) : The Orbital Motion in the (K. Aa. Strand), 283
Cyrenaica and Tripoli : Ancient Monuments of (Prof. J. L. Myres), 381
Cytology of *Rhoeo discolor* and Tradescantia (P. N. Bhaduri), 56
Cytology, Genetics and Evolution (M. Demerec and others), *review* by Dr. C. D. Darlington, 180
Cytoplasmic Inclusion in Virus-infected Plants (B. Kassanis and Dr. F. M. L. Sheffield), 337
Czech Contributions to Botany : Some Early (Dr. Gerald Druce), 98
Czechoslovak Contributions to Genetics (1866–1938) (Dr. Gerald Druce), 495
Czechoslovak Degrees at Oxford, 274
Czechoslovak Medical Students at Oxford (Prof. John Read), 366 ; (Dr. R. Fitzgibbon Young), 450

DADAR, Bombay : The Operation of a Sewage Purification Plant at (N. V. Modak), 646
Darkness : Expediting Visual Adaptation to (Prof. Krikor Kekcheyev), 617
Darwin's Health (Sir Buckston Browne), 14
Data : Engineering, *review*, 349
Deaf Persons (Partially) : A New Telephone Set for (A. Herckmans), 79
Death' ('High-Altitude) of Airmen : Anoxæmic Changes in the Liver, with regard to the (Dr. Peter Ladewig), 558
Death-rate Variation in Fowls and Geographical Latitude (E. Penionzhkevich), 644
Deaths from Exposure to Cold, 695
Decency : Science, Common Sense and (Dr. Irving Langmuir), 266 ; (Adam Gowans Whyte), 450 ; (A. J. Bateman), 450 ; (William P. D. Wightman), 589 ; (E. Denne), 589
Defects of Speech, *review* by Dr. L. E. C. Hughes, 292
Deformations (Large Elastic) : Theory of (Dr. L. R. G. Treloar), 616
Dehydrated Vegetables : Stability of Ascorbic Acid in (Dr. W. R. Aykroyd), 22
Democracy (British) : A Comment on (Sir Hector Hetherington), *review* by R. Brightman, 543
Demonstrations of Base Exchange (S. Mattson), 702
Denervated Muscle : Onset of Fibrillation in (Dr. G. Weddell, Dr. B. Feinstein and R. E. Pattle), 449
Density of Crabs and Lobsters (A. G. Lowndes), 336
Density of Frequencies in Lattice Dynamics (Prof. Max Born), 197 ; (Dr. Walter Ledermann), 197

Dental (Medico-) History of Cloves (Dr. Eugene L. Molnar), 194
Deserts : Role of Blue-Green Algæ in Nitre Formation in (S. V. Odintzova), 701
Design (Transmission-Line) : Some Problems in (A. Burke), 106
Detection of Acid or Basic Substances in Damaged Fabrics (Dr. C. Whitworth and D. W. Poxon), 198
Detector (Electrical) of Condensation in High-Velocity Steam (A. M. Binnie and J. R. Green), 283
Determining the Future, 157
Deuterium Chloride : Preparation of (H. C. Brown and C. Groot), 57
Development : Polygenic Balance in the Canalization of (Dr. K. Mather), 68
  Scientific Research and, 203
Development (Hydro-Electric) : in Great Britain (Prof. R. S. Hutton and O. W. Roskill), 335
  In Scotland, 528 ; (Report of the Cooper Committee), 177, 187
Development and Mortality of *Tribolium destructor* Uyttenboorgaart (*Coleoptera, Tenebrionidae*) : Effect of Parental Feeding on the Rate of (J. M. Reynolds), 55
Development (Colonial) and Welfare : Statement of Policy on, 315
Developments and Reconstruction ; Hydro-Electric, 177
Diameters of Extragalactic Nebulæ (Dr. H. Shapley), 57
Diamond : Laboratory Synthesis of (F. A. Bannister and Dr. K. Lonsdale), 334 ; (Lord Rayleigh), 394
Diatom New to Britain (Frederick Burke and John R. Carter), 672
Dielectric Breakdown : Theory of (Dr. H. Fröhlich), 339
Diesel Engines : High-Speed (Arthur W. Judge), fourth edition, revised and enlarged, *review* by Prof. S. J. Davies, 40
Diphenylethylamine and related Compounds : Morphine-like Properties of (Prof. E. C. Dodds, W. Lawson and P. C. Williams), 614
Discoveries by Accident: (Dr. Norman R. Campbell), 25 ; (Dr. J. C. Chaston), 55
  Scientific (T. Ll. Humberstone), 215
Discovery Reports, Vol. 21 (1942), 647
Disease : Social and Industrial Environment and (Prof. M. Greenwood), 275
  Venereal (Major J. Marshall), 46 ; in Britain (Sydney M. Laird), *review*, 683
  War and (Dr. Ralph H. Major), *review* by Major J. Marshall, 627
Disease in Australasia : Cobalt and other Trace Elements in relation to (Sir Charles Martin), 29
Disease and the Social System : Personality, (P. J. Kloppers), 705
Disease (Animal) in India : Climate and (Dr. F. C. Minett), 733
Disease (A Grain-Borne) of Barley, 369
Disease ('Pasmo') of Flax (John Colhoun and Arthur E. Muskett), 223
Diseases (Children's) : Folk-Lore of (Dr. J. D. Rolleston), 193
Diseases (Infectious) : Control of (Dr. Robert Cruickshank), 330
Diseases of Plants and Animals : Significance of Trace Elements in relation to (Dr. H. H. Green), 28
Disinfection of Cereal Seed, 194
Disorders (Anti-Social Behaviour) : The Differentiation, Prevention and Treatment of (Dr. Norwood East), 9
Dispersal (Seed) by Human Activity (A. J. Healy), 140
Dispersion (Optical) for Coals (C. G. Cannon and Dr. W. H. George), 225
Distribution and Origin of British Lepidoptera (B. P. Bierne), 701
Dockyard Schools (Royal) : Centenary of the, 388
Dog and Cat : A Nuclear Ring in the Developing Male Germ Cells of (I. Zlotnik), 670
Domestic Economy of the United States (Committee of the Editors of *Time, Life* and *Fortune* report on the), 343
Dominions (Great Britain and the) : Physical Education in (Miss P. Spafford), 193
Douglas Fir in Great Britain : Cultivation of the (Alexander L. Howard), 492 ; *erratum*, 557
Downing Street and the Colonies (Fabian Colonial Bureau report), 401
Drainage : of Agricultural Land (H. H. Nicholson), 114
  Oil Well (Dr. Stanley C. Herold), *review* by H. B. Milner, 38
Draper Medal for 1942 of the U.S. National Academy of Sciences awarded to Dr. Ira Sprague Bowen, 721
Driffield (Hurter and) : Sensitometry since (Dr. S. O. Rawling), 210
Drosophila pseudo-obscura : Effect of X-Rays on (P. C. Koller and I. A. R. S. Ahmed), 56 ; (R. G. Helfer), 56
Duchesne River : Mammalian Fauna of the (William B. Scott), 337
Duddell Medal for 1942 awarded by the Physical Society to Dr. C. R. Burch, 218
Dynamics of Real Crystals (Dr. N. S. Nagendra Nath), 196
Dynamics of the Stellar System, *review* by Sir Arthur Eddington, 91
Dynamics (Lattice) : Density of Frequencies in (Prof. Max Born), 197 ; (Dr. Walter Ledermann), 197
Dynamics (Stellar) ; Principles of (S. Chandrasekhar), *review* by Sir Arthur Eddington, 91
Dynamist : "Vis et Præterea Nihil"—The Psychology of a, *review* by Dr. J. Leycester King, 150

EARTHQUAKE : in the Aleutian Islands Archipelago on January 27, 530
  in the mid-north Atlantic on December 31, 362
  at Bhuj on October 31, 136
  in Chile on April 6, 669
  to the east of Chimalapa in the Isthmus of Tehuantepec in Central America on November 12, 106
  in Colombia on December 26, 669
  near Guayaquil in Ecuador on January 30, 530
  in Guatemala (south-east of Sta. Cruz Quiche) on January 24, 530
  at Gulmarg on August 3, on August 8, and on September 21, 136
  at Novelda-Monforte on January 21, 584
  to the west of Prince Edward Island on November 10, 106
  in the Sierra Tejada on January 9, 584
  at Srinagar on September 21, and on December 25, 136
  at Wairarapa on June 24, 1942, 229
Earthquakes : registered in India during 1940, 136
  registered at Kew during April, 669
  registered in New Zealand during November, 1942, 331 ; during January, 694
  registered in Spain during September, 51 ; during October, 194 ; during January, 584 ; during March, 695
  Recent, 106, 530
  reported to J. M. Sil, 136
  Turkish, 19
Earthworms : Nephridia of (K. N. Bahl), 112
Echinocorys (English Senonian) : An Application of the Principles of Allometry to the Study of (Dr. John F. Hayward), 617
Eclipse of the Sun in A.D. 45 (C. J. Westland), 111
Ecology : Staffordshire, 302
Economic Reconstruction, 343
Economic (Political and) Planning, 372
Economics : Engineering (Sir Frank Gill), 387 ; (Prof. R. O. Kapp), 387
Economics and Politics in the South Seas, *review* by Dr. Lucy Mair, 625
Economy (Domestic) of the United States (Committee of the Editors of *Time, Life* and *Fortune* report on the), 343
Economy (National) : Coal Utilization Research and the, 709
Economy (War) : Potatoes and (Dr. Maurice Copisarow), 421 ; (Dr. Nicholas Polunin), 587
Ecuador (near to Guayaquil): Earthquake on January 30, 530
Eddy Current Losses in Single-Conductor Paper-Insulated Lead-Covered Unarmoured Cables of a Single-Phase System (Dr. A. H. M. Arnold), 88
Educating (Re-) the Germans (Prof. T. H. Pear), 684
Education : a Plan for the Future (Association of Directors and Secretaries for Education), 149
  Axis Oppression of (Inter-Allied Information Committee report on), 148
  in the British Army (Lieut. T. H. Hawkins), 438
  for Citizen Responsibilities (John M. Clark, Lloyd Allen Cook and Stuart A. Queen, Frank D. Graham, Richard Hartshorne, William Ernest Hocking, Roy F. Nichols and Arthur C. Bining, Frederic A. Ogg, Ernest Minor Patterson, Calvin P. Stone, Griffith Taylor, Wilson D. Wallis), 483
  for Citizenship, 483
  and the Colonies (Prof. A. V. Hill), 360
  Industry and, 287
  Museums and (G. F. Westcott), 160
  Post-War Agricultural (Ronald Ede), 673 ; Report of the Committee on, 539
  as a Scientific Study, *review* by T. Raymont, 460
  Visual Aids to, 637
  for a World Adrift (Sir Richard Livingstone), *review* by Lieut. T. H. Hawkins, 513
Education in England: The Study of (Prof. F. Clarke), *review* by T. Raymont, 460
Education in H.M. Forces: Civilian Contribution to, 648
Education Interrupted by War Service: Continuation of, 388
Education in the U.S.S.R., People's Commissar for : Institution of Newton scholarships for Soviet university students, 106
Education (Adult) in H.M. Forces : Report of the Central Advisory Council for, April–September, 1942, 648
Education (Agricultural) in Great Britain, 143
Education (Part-time Day) ; for the Adolescent (British Association for Commercial and Industrial Education), 567
Education (Health) : Preparation of Teachers in, 593
Education (Physical) in Great Britain and the Dominions (Miss P. Spafford), 193
Education (Religious) and a New Solution : The Riddle of (Adam Gowans Whyte), *review*, 95
Education (Sex) and Guidance (Dr. R. Sutherland), 356
Education (Technical) to the Building Industry: Relation of, 427
Education (University) : Future of (Prof. J. A. Crowther), 171
Education (World) : The Place of the Universities in (Miss H. Wodehouse), 148
Educational Principles, *review* by Lieut. T. H. Hawkins, 513
Educational System : Science and the, 156
Efficiency : Human Vitality and (A. F. Dufton), 476
Efficiency (Health and) : Hours of Work and their Influence on (Dr. H. M. Vernon), 651
Efficiency (Industrial) : Research and, 259
Egyptian Wadis near Cairo : Flora of the (Col. W. R. Roberts), 20
Einstein (Aristotle, Newton,) (Prof. E. T. Whittaker), 59
Elastic Deformations (Large) : Theory of (Dr. L. R. G. Treloar), 616
Elasticity Measurements (X-Ray) for Mild Steel in Compression (S. L. Smith and W. A. Wood), 113
Electric Discharge : A Light Effect in Chlorine under ; Influence of the Intensity and Frequency (Prof. S. S. Joshi and P. G. Deo), 561
Electric Power System Control (H. P. Young), *review*, 349
Electric Power Systems : Protection of, *review* by Dr. L. E. C. Hughes, 683
Electric Spark : Mechanism of the (Prof. Leonard B. Loeb and John M. Meek), *review* by Dr. T. E. Allibone, 178
Electrical Aspects of Ferro-Alloy Manufacture (H. A. Sieveking), 301
Electrical Counting, with Special Reference to Counting Alpha and Beta Particles (Dr. W. B. Lewis), *review* by Dr. L. Janossy, 377
Electrical Detector of Condensation in High-Velocity Steam (A. M. Binnie and J. R. Green), 283
Electrical Engineering Practice (J. W. Meares and R. E. Neale), fifth edition, Vol. 2, *review*, 378
Electrical Frequency Divider : A New (F. R. Stansel), 621
Electrical Installations in Hospitals (F. Charles Raphael), 557
Electrical Instrument (Moving-Iron : Law of the (Dr. G. F. Tagg), 423
Electrical Instruments (Soft-Iron) : Torque of (Dr. C. V. Drysdale), 423
Electrical Measurement : Standards of (Dr. L. Hartshorn), 221
Electrical Resistance of Wood (W. W. Barkas, R. F. S. Hearmon and G. H. Pratt), 83
Electrical Substations : Ventilation of (F. Favell and E. W. Connon), 500
Electrical Tariffs : Multi-Part Domestic, 220
Electrical Technology, *review* by Dr. L. E. C. Hughes, 713
Electrical Technology for Telecommunications (W. H. Date), *review* by Dr. L. E. C. Hughes, 378
Electricity : Applied (A. W. Hirst), *review* by Dr. L. E. C. Hughes, 713
Electricity : Franklin's Experiments and Observations on (edited by I. Bernard Cohen), *review* by Prof. C. T. R. Wilson, 430
Electricity in Mine Pumping : Application of (G. B. Alvey and N. Tetlow), 79
Electricity Supply Tariffs : General Factors Affecting the Unification of (C. T. Melling), 301
Electro-Biology : Amplifying and Recording Technique in (G. Parr and W. Grey Walter), 330
Electro-Encephalographic Potentials : The Encephalophone, a New Method for Investigating (Dr. R. Fürth and Dr. C. A. Beevers), 110

Electrolytes (Typical Colloidal) : Freezing-Points of Solutions of (S. A. Johnston and J. W. McBain), 478
Electrolytic Oxidation of Formaldehyde (A. Hickling and F. Rodwell), 702
Electrometallurgical Industry : Recent Advances in (Dr. J. W. Cuthbertson), 676
Electron Diffraction (Prof. G. P. Thomson), 530
Electron-Microscopic Examination of Tissues (Fritiof Sjöstrand), 725
Element 85 : Name for (C. W. Martin), 309
Elliot Medal of the U.S. National Academy of Sciences: for 1935 awarded to Dr. Edwin H. Colbert, 722; for 1936 awarded to Dr. Robert Cushman Murphy, 722
Empire Timbers : Handbook of, War Emergency Supplement (edited by H. A. Cox), 732
Emulsions and their Technical Treatment : The Theory of (Dr. William Clayton), fourth edition, *review* by Dr. A. E. Alexander, 542
Encephalographic (Electro-) Potentials : The Encephalophone, a New Method for Investigating (Dr. R. Fürth and Dr. C. A. Beevers), 110
Encephalophone (The), a New Method for Investigating Electro-Encephalographic Potentials (Dr. R. Fürth and Dr. C. A. Beevers), 110
Endocrinology : Appointment of a new editorial board, 303
Endocrinology : Third Pan-American Congress of, to be held at Buenos Aires during July, 249
Enemy : Hatred of the (Dr. R. H. Thouless), 684
Energy : The Concept of (Dr. A. E. Bell), 519
Energy of Nations : Climate and the (S. F. Markham), *review* by Prof. H. J. Fleure, 431
Engineer : The Making of an (A. Reyrolle and Co., Ltd.), *review* by Prof. Willis Jackson, 570
Engineer or Physicist ? (Dr. Percy Dunsheath), 134
Engineer's Year-Book of Formulæ, Rules, Tables, Data and Memoranda for 1943 (H. R. Kempe and W. Hanneford-Smith), 49th annual issue, *review*, 349
Engineering (Highway) at the University of the Witwatersrand : Dr. Bernard H. Knight appointed to the chair of, 164
Engineering (Marine) : Scholarships in (Institution of Naval Architects), 20
Engineering: Modern (C. H. S. Tupholme), *review* by Dr. L. E. C. Hughes, 208
Engineering Data, *review*, 349
Engineering Economics (Sir Frank Gill), 387 ; (Prof. R. O. Kapp), 387
Engineering Mathematics : Relaxation Methods in, 723
Engineering (Electrical) Practice (J. W. Meares and R. E. Neale), fifth edition, Vol. 2, *review*, 378
Engines : High-Speed Diesel (Arthur W. Judge), fourth edition, revised and enlarged, *review* by Prof. S. J. Davies, 40
Engines (Heat) : Theory and Practice of (D. A. Wrangham), *review* by Dr. O. A. Saunders, 571
England : Industrial Fluorosis of Animals in (F. Blakemore), 30
  The Study of Education in (Prof. F. Clarke), *review* by T. Raymont, 460
English Lakeland Fauna, 51
English Senonian Echinocorys : An Application of the Principles of Allometry to the Study of (Dr. John F. Hayward), 617
Entropy : Nature of (Ian D. Campbell), 138 ; (Prof. H. S. Allen), 225 ; (Sir James Swinburne), 335 ; (M. W. Thring), 672
Environment (Social and Industrial) and Disease (Prof. M. Greenwood), 275
Enzootic Ataxia or 'Swayback' of Lambs in England in relation to Copper Feeding of Ewes during Pregnancy (Prof. T. Dalling), 29
Enzymatic (Co-) Reactions (Prof. J. K. Parnas), 577
Enzyme Systems : Copper, Zinc and other Trace Elements in relation to Physiological Function and (Dr. H. Mann and Prof. D. Keilin), 28
Ephemeroptera or Mayflies : Keys to the British Species of (D. E. Kimmins), 112
Epidemiology of Leprosy (Dr. G. W. McCoy), 695
Epilepsy : Folk-Lore of (Dr. J. D. Rolleston), 556
Equilibrium and Kinetics of Gas Reactions (Robert N. Pease), *review* by Dr. C. H. Bamford, 320
Eradication of Wild Onion (J. R. Tinney), 300
Erne (River) : Salmon of the, 282
Eskimo Craniology (Dr. G. M. Morant), 59
Esperito, Da Raça el do (Prof. A. A. Mendes Corrêa), 300
Estimation of Vitamin A (Miss E. M. Hume), 535
Estimation (Spectrophotometric) of Vitamin A in Fish Liver Oils (J. I. M. Jones and R. T. M. Haines), 57
Etching on Metals : A New Method of (Griffin and Tatlock, Ltd.), 361
Ethanol-Methanol at 40° : The System (A. C. Morris, L. T. Munn and G. Anderson), 142
Ethics : Science and (Dr. C. H. Waddington), *review*, 657
Ethnologist : A Great, *review* by Dr. C. S. Myers, 4
Ethnology (History and) of the Caddo Indians (John R. Swanton), 644
Europe : Chemical Industry in, 50
  Reconstruction and a Council of (Winston Churchill), 359
  The State of Health in, 117
Europe (Devastated), Restarting Agriculture in (Sir John Russell), 433
European Agriculture : Co-operative Systems in (British Association, Division for the Social and International Relations of Science, conference on), 418, 523
Evolution : in Action, *review* by Dr. Julian Huxley, 347
  in Astronomy (Sir James Jeans), 7
  of Colonial Territories, 360
  Cytology, Genetics and (M. Demerec and others), *review* Dr. C. D, Darlington, 180
  of International Trade (Prof. A. G. B. Fisher), 500
  in Plants by Kaleidoscopic Mutation (Dr. J. C. Willis), 283
  of the Cultivated Tomato (Dr. L. C. Luckwill), 300
  of Wire Telephony (George H. Gray), 227
Evolutionary Processes in Crepis (E. G. Babcock, G. L. Stebbins and J. H. Jenkins), 701
Ewes during Pregnancy : Enzootic Ataxia or 'Swayback' of Lambs in England in relation to Copper Feeding of (Prof. T. Dalling), 29
Ewing (James Alfred) Medal for 1942 awarded to Dr. R. E. Stradling, 136
Excretion (Absorption and) of Trace Elements (Miss E. M. Widdowson and Dr. R. A. McCance), 30
Exotic Woodlice in the British Isles (Dr. Walter E. Collinge), 394
Expediting Visual Adaptation to Darkness (Prof. Krikor Kekcheyev), 617
Exposure to Cold : Deaths from, 695
Extragalactic Nebulæ : Diameters of (Dr. H. Shapley), 57
Eye (The Vertebrate) and its Adaptive Radiation (Gordon Lynn Walls), *review* by Prof. H. E. Roaf, 236
Eye-Spot of Wheat and Barley (Miss Mary D. Glynne), 142

FABRICS (Damaged) : Detection of Acid or Basic Substances in (Dr. C. Whitworth and D. W. Poxon), 198
Factors in the Production of Leaf Palisade Tissue (R. W. Watson), 113
Factors (Supernormal) in Human Personality (Dr. B. L. Atreya), 556
Factory (Welfare Outside the) and Seamen's Welfare in Port (Report issued by the Ministry of Labour and National Service), 116
Factory Medical Services and Industrial Diseases : Week-end course on (London School of Hygiene and Tropical Diseases), 106
Faraday Medal of the Institution of Electrical Engineers awarded to Sir Archibald Page, 191
Farm Animals : 'Teart' of Somerset, a Molybdenosis of (W. S. Ferguson), 30
Farm Crops (New) for Australia (A. McTaggart and T. B. Paltridge), 445
Farm and Forest in Colonial Administration, 652
Fauna : English Lakeland, 51
Fauna (Insect) of Norfolk Island (C. N. Hawkins), 141
Fauna (Mammalian) of the Duchesne River (William B. Scott), 337
Fear of Freedom (Dr. Erich Fromm), *review* by Dr. H. G. Baynes, 597
Federation (World) : Anglo-American Union as a Nucleus of (Prof. George Catlin), 77
Feeding : Breast and Bottle, 687
Feeding (Communal) : Problems of, 134
  Soviet Forms in (F. le Gros Clark), 134
Feeding (Planned) in Great Britain : Four years of (Dr. Magnus Pyke), 658
Fenugreek Seeds : The Saponin of (Dr. Gabra Soliman and Miss Zahira Mustafa), 195
Fermi-Dirac Statistics : 'Condensation' in (Prof. D. S. Kothari and Brij Nath), 420
Ferro-Alloy Manufacture : Electrical Aspects of (H. A. Sieveking), 301
Fertility (Soil) : Leaf Analysis as a Guide to (Prof. H. Lundegårdh), 310
Fevers (Common) : Control of the (Twenty-one Contributors, arranged with the help of Dr. Robert Cruickshank by the Editor of the *Lancet*), *review*, 151
Fibres (Keratin) : Structure of (Dr. J. L. Stoves), 304
Fibres (Giant Myelinated) in the Prawn, *Leander serratus* (William Holmes), 282
Fibrillation in Denervated Muscle : Onset of (Dr. G. Weddell, Dr. B. Feinstein and R. E. Pattle), 449
Fibrinogen and Fibrin as Members of the Keratin-Myosin Group (Dr. K. Bailey, Dr. W. T. Astbury and Dr. K. M. Rudall), 716
Field Fellowship (H. J. Massingham), *review* by Dr. E. W. Russell, 37
Fish : Trawling and the Stocks of (Dr. E. S. Russell), 323
Fish Liver Oils : The Spectrophotometric Estimation of Vitamin A in (J. I. M. Jones and R. T. M. Haines), 57
Fish and Fisheries of Lake Nyasa : Report on the (C. K. Ricardo Bertram, H. J. H. Borley and Ethelwynn Trewavas), *review* by Michael Graham, 655
Fisheries (Freshwater) in the British Colonial Empire (Dr. E. B. Worthington), 353
Fisheries (Prawn) of India (Dr. B. Chopra), 556
Fishes of the Genus Bothriolepis (Walter Gross), 56
Flame Spectra in the Photographic Infra-Red (A. G. Gaydon), 645
Flax : 'Pasmo' Disease of (John Colhoun and Arthur E. Muskett), 223
Floatless Liquid Level Control (Londex, Ltd.), 135
Floatless Pump Control System, 135
Flocculation of Bacteria by Protozoa (Garrett Hardin), 642
Flora : of Bombed Areas (Prof. E. J. Salisbury), 462
  of the Egyptian Wadis near Cairo (Col. W. R. Roberts), 20
  of India and Burma : Systematic and Taxonomic Studies on the (Dr. Kalipada Biswas), 580
Florida : Crayfishes of (Horton H. Hobbs, jun.), 337
Flour (National) : Estimation of Added Calcium Carbonate (Creta Præparata) in (E. N. Greer, J. D. Mounfield and W. J. S. Pringle), 27
Flour and Bread (National) : Third Report, 629
Fluids (Biological) : Determination of the Osmotic Pressure of (Dr. R. Aschaffenburg), 169
Fluorescence of Anthracene in Presence of Naphthacene (S. C. Ganguly), 673
Fluorescence by Nitric Oxide : Quenching of (Dr. H. Weil-Malherbe and Dr. Joseph Weiss), 449
Fluorescent Lamps, their Photometric and Colour Rendering Properties and Measurement (G. T. Winch), 73
Fluorescent Pigments in Colour Printing : The Use of (F. W. Coppin), 73
Fluorescent Substances : Commercially Useful (H. G. Jenkins), 73
Fluorine in Human Nutrition (Dr. M. M. Murray, Dr. D. C. Wilson and F. H. Kemp), 30
Fluorine on the Teeth of Rachitic Rats : Action of (Prof. J. T. Irving), 363
Fluorosis (Industrial) of Animals in England (F. Blakemore), 30
Folk-Lore : of Children's Diseases (Dr. J. D. Rolleston), 193
  of Epilepsy (Dr. J. D. Rolleston), 556
Food (Home-Grown) in Britain : Wild Birds and (Dr. Walter E. Collinge), 128
Food Yeast, 274
  Value of Micro-Organisms in Nutrition (Dr. A. C. Thaysen), 406
Food and Pregnancy, 321
Food, Health, Vitamins : (Prof. R. H. A. Plimmer and Violet G. Plimmer), ninth edition, *review*, 572
Foods (Brazilian) : Vitamin Content of (Dr. Moura Campos), 584
Forces (H.M.) : Civilian Contribution to Education in, 648
  Report of the Central Advisory Council for Adult Education in, April–September 1942, 648
Forest Products : Swedish, 165
Forest Tree Seed of the North Temperate Regions, with Special Reference to North America (Henry Ives Baldwin), *review* by T. Thomson, 93
Forest (Farm and) in Colonial Administration, 652
Forestry in Trinidad and Tobago, 284
Formaldehyde : Electrolytic Oxidation of (A. Hickling and F. Rodwell), 702
Formation of Planetary Systems (B. M. Peek), 200

Forrest (James) Lecture of the Institution of Civil Engineers on the Extreme Properties of Matter (Sir Charles Darwin), 237
Forum : Nottingham Open, 18
Foster (Peter Le Neve) Lecture to the Royal Society of Arts (Dr. C. H. Desch), 692
Foundations of Astronomy (Prof. W. M. Smart), *review* by Dr. J. C. P. Miller, 38
Fowls and Geographical Latitude : Death-rate Variation in (E. Penionzhkevich), 644
Franklin's Experiments and Observations on Electricity (edited by I. Bernard Cohen), *review* by Prof. C. T. R. Wilson, 430
Free Will (Physics, Materialism, and) (Prof. L. Susan Stebbing), 686
Freedom : The Fear of (Dr. Erich Fromm), *review* by Dr. H. G. Baynes, 597
Freedom in Science (Dr. H. Lowery), 295
Freewill, (Chance,) and Necessity in the Scientific Conception of the Universe (Prof. E. T. Whittaker), 612
Freezing-Points of Solutions of Typical Colloidal Electrolytes (S. A. Johnston and J. W. McBain), 478
Frequencies in Lattice Dynamics : Density of (Prof. Max Born), 197 ; (Dr. Walter Ledermann), 197
Frequency Divider : A New Electrical (F. R. Stansel), 621
Frequency Equipment : New Reference (V. J. Weber), 301
Freshwater Fisheries in the British Colonial Empire (Dr. E. B. Worthington), 353
Frictional Properties of Metallic Films (Dr. Robert Schnurmann), 420 ; (Dr. T. P. Hughes), 533
Fruit from the Garden (J. M. S. Potter), 20
Fruit Culture, *review* by Dr. R. G. Hatton, 92
Fruit Growing, 20
Fruit Production : Modern (Prof. Joseph Harvey Gourley and Prof. Freeman Smith Howlett), *review* by Dr. R. G. Hatton, 92
Fuel Testing (Dr. Godfrey W. Himus), second edition, *review*, 600
Function (Growth,) and Inheritance : Seasonal Influence on (A. B. Fitt), *review* by Prof. W. E. Le Gros Clark, 66
Fungi : Researches on, *review* by E. W. Mason, 208
Fungus : Luminosity a Mendelian Character in a (Ruth Macrae), 113
Fungus *Fusarium culmorum* : Colonization of Buried Wheat Straw by the (Alan G. Walker), 283
Fungus *Ophiobolus graminis* (S. D. Garrett), 283
Future : of the Continuation School, 567
    Determining the, 157
    of University Education (Prof. J. A. Crowther), 171

GARDEN : Fruit from the (J. M. S. Potter), 20
Gas : Accuracy of Boyle's Original Observations on the Pressure and Volume of a (Dr. R. C. Geary), 476
Gas Gangrene: Identification of Clostridia of (Dr. G. F. Petrie and D. Steabben), 644
Gas Reactions : Equilibrium and Kinetics of (Robert N. Pease), *review* by Dr. C. H. Bamford, 320
Gas Warfare (Compiled by W. K. Fitch), *review*, 404
Gases (War): their Identification and Decontamination (Dr. Morris B. Jacobs), *review*, 404
Gas-filled Cable : High-pressure (C. J. Beaver and E. L. Davey), 669
General Public : Presentation of Science to a (Dr. Arnold Raestad), 547
Genetics : Some Czechoslovak Contributions to (1866–1938) (Dr. Gerald Druce), 495
    of the Potato (C. H. Cadman), 26
Genetics (Production) in Sweden (Dr. C. D. Darlington), 183
Genetics (Cytology,) and Evolution (M. Demerec and others), *review* by Dr. C. D. Darlington, 180
Geochemical Uranium/Lead Ratio : The 'Age' of Terrestrial Matter and the (F. F. Koczy), 24
Geographical Names, 77
Geography (Physical) at Cambridge : Laboratory for (Prof. F. Debenham), 248
Geological Investigations (Archæological and) in the San Jon District, Eastern New Mexico (F. H. Roberts), 282
Geological Sciences: Terminology in the (Dr. R. H. Rastall), 294, 447; (Prof. A. E. Trueman), 447; (Dr. Alan Wood), 447; (F. Wolverson Cope), 503
Geologists (Geology,) and the War Effort, 118
Geologists (Geology and) in the War and the Peace (Prof. H. H. Read), 119
Geology : Aerial Photography and, *review* by Dr. G. D. Hobson, 459
    in the Museum (Dr. F. J. North, C. F. Davidson and Lieut. W. E. Swinton), *review*, 6
    in Post-War Planning (Prof. P. G. H. Boswell), 493
Geology and Geologists in the War and the Peace (Prof. H. H. Read), 119
Geology, Geologists and the War Effort, 118
Geometry: Non-Euclidean (Prof. H. S. M. Coxeter), *review* by Prof. H. T. H. Piaggio, 94
Geomorphology—Systematic and Regional (Prof. O. D. von Engeln), *review* by Prof. A. E. Trueman, 598
Germ Cells of Dog and Cat (Developing Male) : A Nuclear Ring in the (I. Zlotnik), 670
Germans : Re-educating the (Prof. T. H. Pear), 684
Germany : Synthetic Textile Research in, 115
Germination Tests (Spore) : Behaviour of Thiuram Sulphides, etc., in (H. B. S. Montgomery and Dr. H. Shaw), 333
Gibbs (Willard) Medal awarded to Prof. C. A. Elvehjem, 471
Gibraltar : Discovery of an unknown cavern by tunnellers of the Royal Engineers, 362
Glass : New Uses for (Prof. W. E. S. Turner), 173 ; *errata*, 194
    Utilization of, 173 ; *errata*, 194
Glass Polishing: The Art of, *review* by H. W. Lee, 458
Glass Technology, Journal of the Society of, Vol. 26, No. 116, 106
Glassware : Cords, Surface Condition and Quality of, 106
Glycolesters : New Synthesis of (M. S. Kulpinski and Prof. F. F. Nord), 363
Golden Gate Bridge : Instruments installed for recording movements under wind loads, 331
Golgi Apparatus in *Astasia Harrisii* (J. D. Smyth), 110
Government : The British Method of (A. K. White), *review* by R. Brightman, 543
    Machinery of : Methods and Men, 1
    Science and (Sir John Anderson), 219 ; *erratum*, 249
Government and Science in Great Britain (Sir Stafford Cripps), 152, 154, 203
Government Grant to Universities, 165
Grain in Cereals : Auxin Production during Development of the (Dr. E. S. J. Hatcher), 278
Grain for Storage : Automatic Separation of Wet from Dry (T. A. Oxley and Dr. F. Y. Henderson), 223
Grain-Borne Disease of Barley, 369
Gram : Mutations in, 283
Gram-staining Reaction for Micro-organisms : Histochemistry of the (Dr. H. Henry and Dr. M. Stacey), 671
Graphite: Crystal Structure of (Dr. H. Lipson and A. R. Stokes), 27
Grass (Artificially Dried) : Production of (J. McNair and A. B. Fowler), 529
Grass Seedling : Physiology of the (R. L. Weintraub and E. D. McAlister), 477
Grasses (Soils and) : Distribution of Trace Elements in (Dr. R. L. Mitchell), 28
Great Britain : Agricultural Education in, 143
    Agricultural Research in (Agricultural Research Council report on), 396
    American Library in, 612
    Post-War Civil Aviation in, 175
    Chemists in, 191
    Introduction of Chinese Plants to, 136
    Coal Conservation in, 61
    Cultivation of the Douglas Fir in (A. L. Howard), 492; *erratum*, 557
    Four Years of Planned Feeding in (Dr. Magnus Pyke), 658
    Government and Science in (Sir Stafford Cripps), 152, 154, 203
    The Grid and Secondary Power Stations in, 565
    Health Services in, 312, 498
    Hydro-Electric Development in (Prof. R. S. Hutton and O. W. Roskill), 335
    Industrial Research in, a Policy for the Future (Dr. P. Dunsheath), 259
    Location of Industry in, 565
    Planning the Land of, 623
    Indigenous Malaria in (Sir Arthur MacNalty), 440
    Regional Boundaries in (Association for Planning and Regional Reconstruction), 584
    Organization of Science in, 206
    (Standardization in) of Single-Circuit Overhead Lines up to 33kV. (H. Willott Taylor and K. L. May), 445
    The Public Library System of (L. R. McColvin), 317
    Russian Scientific and Technical Periodicals in, 77
    Venereal Disease in, *review*, 683
Great Britain and Latin American Culture, 274
Great Britain and China (Sir John Pratt), 77
Great Britain and the Dominions : Physical Education in (Miss P. Spafford), 193
    See also under Britain
Greece (Lieut.-Col. Stanley Casson), 77
Greece : British Archæologists in, *review* by Prof. John L. Myres, 65
'Greensalt' Preservative for Telephone Poles (C. M. Hill), 302
Greenwich Astrographic Zone : Obscured Regions in the (E. G. Martin), 27
Grid (The Effect of the National) on the Operation and Maintenance of Secondary Power Stations (R. A. W. Connor), 565
Growth : Chemical Background of, *review* by Sir Joseph Barcroft, 402
Growth of Brown Trout (*Salmo trutta* L.) in Alkaline and Acid Waters (A. E. J. Went and Winifred E. Frost), 26
Growth Stimulators in Urinary Extracts (J. H. Thompson, Dr. P. F. Holt and Dr. R. Forbes Jones), 23
Growth (Tissue) : Pantothenic Acid in (H. McIlwain), 56
Growth, Function and Inheritance : Seasonal Influence on (A. B. Fitt), *review* by Prof. W. E. Le Gros Clark, 66
Growth Inhibitor : A Synthetic Differential (P. B. Medawar, Lady Robinson and Sir R. Robinson), 195
Guatemala (south-east of Sta. Cruz Quiche) : Earthquake on January 24, 530
Guayaquil (near to) : Earthquake on January 30, 530
Guides (War-time) to British Sources of Specialized Information, No. 4, 77
Gulmarg : Earthquakes on August 3, August 8, and September 21, 136
Guthrie Lecture of the Physical Society (Prof. E. T. Whittaker), 612

HADDON, the Head Hunter (A. Hingston Quiggin), *review* by Dr. C. S. Myers, 4
Hæmoglobin : (Reactions of) and its Derivatives with Phenyl Hydroxylamine and Nitrosobenzene (Prof. D. Keilin and Dr. E. F. Hartree), 390
    X-Ray Analysis of (Joy Boyes-Watson and M. F. Perutz), 714
Half-Value Periods : Determination of (A. G. Ward), 338
Harben Gold Medal awarded to Sir Henry Dale by the Royal Institute of Public Health and Hygiene, 446
Hardness of Silver Alloys (J. H. Frye, jun., and W. Hume-Rothery), 57
Harris and Abbasy : Vitamin C Saturation Test of (Dr. W. R. G. Atkins), 21
Hatred of the Enemy (Dr. R. H. Thouless), 684
Head Musculature of Coleoptera, 644
Health : of American Troops Abroad, 529
    in Industry, 200
    in Paris, 530
    Trace Elements in relation to (Nutrition Society conference on), 28
Health in Europe : The State of, 117
Health (Public) in Chile, 135 ; (Dr. Juan Antonio Rios), 668
Health, (Food,) Vitamins (Prof. R. H. A. Plimmer and Violet G. Plimmer), ninth edition, *review*, 572
Health Education : Biology and (Council for Health Education conference on), 498
    The Methods of (Cyril Bibby), 498
    The Possibilities of (Dr. Robert Sutherland), 498
    Preparation of Teachers in, 593
Health and Efficiency : Hours of Work and their Influence on (Dr. H. M. Vernon), 651
Health Habits and Hazards (Dr. J. F. Galloway), 498
Health Service : A Comprehensive (Prof. Henry Cohen), 498
Health Services in Great Britain, 312, 498
Health (Biology and): Summer School in (Central Council for Health Education), 388, 499

Heat Engines : Theory and Practice of (D. A. Wrangham), *review* by Dr. O. A. Saunders, 571
Heating Systems : Insulation of, 593
Heavens : The Revolving (Reginald L. Waterfield), *review*, 265
Heavy Oxygen (E. R. S. Winter and H. V. A. Briscoe), 142
Hedge and Tree-Stump Clearing (T. Swarbrick), 78
Heliocentric Theory : Copernicus and the (Dr. H. Spencer Jones), 573
Helminthosporium sativum P., K. and B. : Host-Parasite Relationships of Barley and (H. W. Mead), 369
Heredity : Discussing, *review* by Dr. C. D. Darlington, 180
Hexoestrol and of α-Methyl Stilbene on the Insulin Content of the Pancreas of the Rabbit : Effect of (Dr. Mervyn Griffiths), 82
Hexose Dehydrogenase (M. N. Rudra), 641
'High-Altitude Death' of Airmen : Anoxæmic Changes in the Liver, with regard to the (Dr. Peter Ladewig), 558
High Frequency Thermionic Tubes (Dr. A. F. Harvey), *review*, 655
High Polymers : Natural and Synthetic (Prof. Kurt H. Meyer, translated by Dr. L. E. R. Picken), *review* by Prof. H. W. Melville, 682
High-pressure Gas-filled Cable (C. J. Beaver and E. L. Davey), 669
High-Speed Diesel Engines (Arthur W. Judge), fourth edition, revised and enlarged, *review* by Prof. S. J. Davies, 40
Hirsch Medical Scholarship Fund, 557
Histochemistry of the Gram-staining Reaction for Micro-organisms (Dr. H. Henry and Dr. M. Stacey), 671
Historical Method in Teaching Science (Manchester Literary and Philosophical Society discussion on), 417
History : Scientific Approach to, *review* by F. S. Marvin, 486
  What Happened in (Prof. V. Gordon Childe), *review* by M. C. Burkitt, 515
History and its Neighbors (Prof. Edward Maslin Hulme), *review* by F. S. Marvin, 486
History of Science : Studies in the (E. A. Speiser, Otto E. Neugebauer. Hermann Ranke, Henry E. Sigerist, Richard H. Shryock, Evarts A, Graham, Edgar A. Singer, Hermann Weyl), *review* by Dr. W. H. S. Jones, 404
History and Ethnology of the Caddo Indians (John R. Swanton), 644
Holiday Centres : A National Scheme for, 86
Holidays : Planning for (P E P Broadsheet No. 194), 86
Home (School and) : Reconstruction Problems in (Report by the Electrical Association for Women), 417
Home-Grown Food in Britain : Wild Birds and (Dr. Walter E. Collinge), 128
Honours : New Year, 49
  King's Birthday, 636 ; for Canadian Services, 666
Horticultural Expeditions of Ernest Henry Wilson to China (E. H. M. Cox), 136
Hospital Admissions in U.S. Rural and Urban Areas (Selwyn D. Collins), 303
Hospitals : Electrical Installations in (F. Charles Raphael), 557
Host-Parasite Relationships of Barley and *Helminthosporium sativum* P., K. and B. (H. W. Mead), 369
Hours of Work and their Influence on Health and Efficiency (Dr. H. M. Vernon), 651
Human Activities and Soil Characteristics (Dr. F. E. Kenchington), 83
Human Activity : Seed Dispersal by (A. J. Healy), 140
Human Instincts : Are there (Prof. T. H. Pear), *review* by Dr. R. H. Thouless, 489
Human Nutrition : Fluorine in (Dr. M. M. Murray, Dr. D. C. Wilson and F. H. Kemp), 30
Human Personality : Supernormal Factors in (Dr. B. L. Atreya), 556
Human Requirements (Minimum) and the Beveridge Report (Sir Joseph Barcroft, Prof. Stanley Davidson, Sir F. Gowland Hopkins, Lord Horder, Prof. Julian Huxley, Prof. J. M. Mackintosh, Sir Charles Martin, Sir Robert McCarrison, Lord Moran of Manton, B. S. Rowntree, Prof. J. C. Spence and Prof. W. H. Wynn), 422
Human Vitality and Efficiency (A. F. Dufton), 476
Humanity : Science as a (Prof. W. G. de Burgh), 607
Humidity (Effect of Air Currents, Light,) and Temperature on Slugs (Mrs. Barbara H. Dainton), 25
Hurter and Driffield : Sensitometry since (Dr. S. O. Rawling), 210
Huxley Memorial Lecture on North Syria as a Cultural Link in the Ancient World (Sir Leonard Woolley), 144
Hydrocarbon Mixtures : Influence of Water Vapour upon the Combustion of (Prof. W. T. David and J. Mann), 392
Hydrocarbons : Specific Heats of (B. P. Dailey and W. A. Felsing), 702 ; (J. F. Lemons and W. A. Felsing), 702
Hydro-Electric Development in Great Britain (Prof. R. S. Hutton and O. W. Roskill), 335
Hydro-Electric Development in Scotland (Report of the Cooper Committee), 177, 187, 528
Hydro-Electric Developments and Reconstruction, 177
Hydrogen (Ionization in) by Fast Hydrogen Neutrals (Dr. J. D. Craggs), 137
Hydrogen Bond and its Influence on Acid Strength (Rev. Dr. H. O. Jenkins), 561
Hydrogen Neutrals (Fast) : Ionization in Hydrogen by (Dr. J. D. Craggs), 137
'Hyglo' System of Crack Detection in Non-ferrous Metals, 555
Hypopituitarism and Starvation : Relation of (Dr. Erwin P. Vollmer), 698

IDEALS (British) : The Temper of (Prof. John Laird), *review* by R. Brightman, 543
Ideas : War of (Muriel Jaeger), 77
Identification of Clostridia of Gas Gangrene (Dr. G. F. Petrie and D. Steabben), 644
Identification of Indian Timbers, 669
Illustration by Analogy (W. R. Dunlop), 700
Image Diameters in Photographic Photometry : Star Magnitudes and (D. L. Edwards), 31
Immunity to Viruses (Royal Society of Medicine discussion on), 551
Implantation (Delayed) in the Stoat (*Mustela mustela*), (Dr. Ruth Deanesly), 365
Implements (Manufacturing Wooden) by Simple Stone Tools: An Unrecorded Method of (C. B. Mountford), 56
Implements (Wooden) of a Primitive Tribe, 56
Inagua (Gilbert C. Klingel), *review* by Sir D'Arcy W. Thompson, 488
Inclusions (Cytoplasmic) in Virus-infected Plants (B. Kassanis and F. M. L. Sheffield), 337
Incompatibility in Solanum (—. Pushkarnath), 338
India : Botany in (Sir Geoffrey Evans), 580
  Climate and Animal Disease in (Dr. F. C. Minett), 733
  Earthquakes registered during 1940, 136
  Locusts and other Migratory Insects in (Dr. A. D. Imms), 509 ; (Rao Bahadur Y. Ramchandra Rao), 509
  Prawn Fisheries of (Dr. B. Chopra), 556
  Science in (D. N. Wadia), 548
  Scientific and Industrial Research in, 329
India's Mineral Resources (Sir Lewis Fermor), 689
  Suggestions for the Future Development of (Dr. J. A. Dunn), 689
India and Burma : Systematic and Taxonomic Studies on the Flora of (Dr. Kalipada Biswas), 580
Indian Industrial Development : Aspects of, 411
Indian Science Congress :
  Science in India (General presidential address by D. N. Wadia), 548
  Supernormal Factors in Human Personality (Presidential address before the Section of Psychology and Educational Science by Dr. B. L. Atreya), 556
  Prawn Fisheries of India (Presidential Address by Dr. B. Chopra), 556
  Systematic and Taxonomic Studies on the Flora of India and Burma (Presidential Address to the Section of Botany by Dr. Kalipada Biswas), 580
  Fundamental Particles of Physics (Presidential Address to the section of Physics by Dr. H. J. Bhabha), 628
  The Operation of a Sewage Purification Plant at Dadar, Bombay (Presidential Address to the Section of Engineering and Metallurgy by N. V. Modak), 646
  Suggestions for the Future Development of India's Mineral Resources (Presidential Address to the Section of Geology and Geography by Dr. J. A. Dunn), 689
  Climate and Animal Disease in India (Presidential Address to the Section of Medical and Veterinary Sciences by Dr. F. C. Minett), 733
Indian Silicified Plants, I, *Azolla intertrappea* Sahni and H. S. Rao (B. Sahni), 338
Indian Timbers : Identification of, 669
Indians (Caddo) : History and Ethnology of the (John R. Swanton), 644
Indies (British West) : Development and Welfare in the, 1940–1942 (Sir Frank Stockdale's report on), 399
Indigenous Malaria in Great Britain (Sir Arthur MacNalty), 440
Individualist Basis of International Law and Morals (Prof. Morris Ginsberg), 648
Individuality : Authoritarianism versus, *review* by Dr. H. G. Baynes, 597
Industrial Development (Indian) : Aspects of, 411
Industrial Diseases : Factory Medical Services and, Week-end course on (London School of Hygiene and Tropical Diseases), 106
Industrial Efficiency : Research and, 259
Industrial Environment and Disease : Social and (Prof. M. Greenwood), 275
Industrial Experience : Science Students and, 164
Industrial Fluorosis of Animals in England (F. Blakemore), 30
Industrial Management : Science and, 156
  Training for (Institute of Industrial Administration conference on), 221, 340
Industrial Photographers : Scientific and, 501
Industrial Radiography : Some Miscellaneous Applications of (Dr. L. Mullins), 719
Industrial Research in Great Britain, a Policy for the Future (Dr. P. Dunsheath), 259
Industrial Research (Scientific and) in India, 329
Industrial Technology (Science, Inventions and): Stalin Prizes for, 425
Industry : Health in, 200
  Location of (R. G. Glenday), 565
  X-Ray Analysis in (Institute of Physics conference on), 506
Industry (Chemical) in Europe, 50
Industry (Electrometallurgical) : Recent Advances in (Dr. J. W. Cuthbertson), 676
Industry (Modern) in the Netherlands East Indies (Dr. P. H. W. Sitsen), 468
Industry (A New Palæolithic) from the Norfolk Coast (D. F. W. Baden-Powell and J. Reid Moir), 26
Industry (Science and) : Photography in (Herbert E. Zerkowsky), 501
Industry and Education, 287
Infancy : Nutrition in (Nutrition Society conference on), 530, 687
Infant Mortality in the United States (Herbert J. Sommers), 193
Infantile Paralysis : Inheritance of (J. Addair and L. H. Snyder), 477
Infections : Wound, *review* by Prof. A. A. Miles, 209
Infectious Diseases : Control of (Dr. Robert Cruickshank), 330
Influenza, a Survey of the last 50 Years in the Light of Modern Work on the Virus of Epidemic Influenza (F. M. Burnet and Ellen Clark), *review* by Dr. C. H. Andrewes, 263
Influenza Pandemics, Looking Back and Forward, *review* by Dr. C. H. Andrewes, 263
Information (Specialized) : War-time Guides to British Sources of, No. 4, 77
Infra-Red (Photographic): Flame Spectra in the (Dr. A. G. Gaydon), 645
Inheritance of Infantile Paralysis (J. Addair and L. H. Snyder), 477
Inheritance (Growth, Function and) : Seasonal Influence on (A. B. Fitt), *review* by Prof. W. E. Le Gros Clark, 66
Inhibition of Tumour Growth (J. H. Thompson, P. F. Holt and H. J. Callow), 364
Inhibitors (Sulphonamide) : Counteracting (Dr. W. K. S. Wallersteiner), 586
Injury to Bones and Muscles : Influence of a Prolonged Partial Deficiency of Vitamin C on the Recovery of Guinea Pigs from (Dr. E. Kodicek and Dr. P. D. F. Murray), 395
Innervation of Crustacean Muscles (William Holmes), 531
Inorganic Substances : A Course of Instruction in the Qualitative Chemical Analysis of (Prof. Arthur A. Noyes), tenth edition, revised and rewritten by Prof. Ernest H. Smith, *review*, 657
Insect Fauna of Norfolk Island (C. H. Hawkins), 141
Insecticides : The Search for New (Dr. J. R. Busvine), 690
Insects : Vitamins of the B-Group required by (Dr. G. Fraenkel and M. Blewett), 703
Insects, for Collections : Preparation and Preservation of (J. Manson Valentine), 362
Insects in India : Locusts and other Migratory (Dr. A. D. Imms), 509 ; (Rao Bahadur Y. Ramchandra Rao), 509

Insects (Injurious): Place of Research in the Control of (Prof. J. W. Munro), 157
Insects (Scale) of North America: Atlas of the (G. F. Ferris), Fourth Series, *review*, 657
Insemination (Artificial) Centres for Dairy Cows (Dr. S. Bartlett and Dr. J. Edwards), 114
Instinctive Behaviour: The Stereotypy of (Dr. E. S. Russell), 612
Instincts?: Are there Human (Prof. T. H. Pear), *review* by Dr. R. H. Thouless, 489
Instrument (Moving-Iron Electrical): Law of the (Dr. G. F. Tagg), 423
Instrument (Scientific): Photography as a, 718
Instruments (Soft-Iron Electrical): Torque of (Dr. C. V. Drysdale), 423
Insulation of Heating Systems, 593
Insulation (Thermal) at Medium Temperature (A. C. Pallot), 593
Insulin Content of the Pancreas of the Rabbit: Effect of Hexoestrol and of α-Methyl Stilbene on the (Dr. Mervyn Griffiths), 82
Interferometer in Lens and Prism Manufacture (F. Twyman), 43
International Anti-Locust Campaign (Dr. B. P. Uvarov), 41
International Collaboration: Aspects of, 679
International Co-operation, 157
International Law and Morals (Prof. W. G. de Burgh), 648
    The Individualist Basis of (Prof. Morris Ginsberg), 648
International Relations (J. G. Winant), 554
International Trade: Evolution of (Prof. A. G. B. Fisher), 500
Intrusive Rocks, Ontario: Age Determinations of (H. C. Horwood and N. B. Keevil), 701
Inventions (Science,) and Industrial Technology: Stalin Prizes for, 425
Investigations in Afghanistan (K. de B. Codrington), 105
Ion Clusters by X-Rays: Production of (U. Fano), 698
Ionization in Hydrogen by Fast Hydrogen Neutrals (Dr. J. D. Craggs), 137
Ionizing Radiations on Aqueous Solutions: Mode of Action of (Dr. W. M. Dale, W. J. Meredith and M. C. K. Tweedie), 280
Ionosphere: Radio Exploration of the (Sir Edward Appleton), 497
Ionospheric Variations during the Sunspot Cycle, 497
Ireland: Nature and Early Man in, *review* by C. F. C. Hawkes, 376
Irish Stone Age (Dr. Hallam L. Movius, Jr.), *review* by C. F. C. Hawkes, 376
Iron Boulder (Great) from Ovifak (H. Löfquist and C. Benedicks), 26
Irradiation on Tradescantia: Effect of (D. E. Lea and D. G. Catcheside), 338
Island: An Unknown, *review* by Sir D'Arcy W. Thompson, 488
Isomers of Stilboestrol and its Esters (E. Walton and G. Brownlee), 305; (Prof. E. C. Dodds and Sir Robert Robinson), 305
Isopod Crustacea: American Land and Freshwater (William G. Van Name), 282

JACKSON (Herbert) Prize for 1942 of the London Midland and Scottish Railway awarded to J. Dearden, 249
Joints in Submarine Cables (R. Miller and C. T. Rose), 248
Journal of Scientific and Industrial Research (Board and Council of Scientific and Industrial Research in India), 329
Jupiter's South Equatorial Belt: Activity on (B. M. Peek), 331
Juvenile Crime, *review* by Prof. Cyril Burt, 291

KENT: A Handlist of the Birds of the Sevenoaks or Western District of (James M. Harrison), *review*, 151
Keratin Fibres: Structure of (Dr. J. L. Stoves), 304
Keratin-Myosin Group: Fibrinogen and Fibrin as Members of the (Dr. K. Bailey, Dr. W. T. Astbury and Dr. K. M. Rudall), 716
Kew: Earthquakes registered during April, 669
Kine-photo-micrography: Sub-standard (C. D. Reyersbach), 720
Kinetics of Gas Reactions: Equilibrium and (Robert N. Pease), *review* by Dr. C. H. Bamford, 320
Kinetics (Chemical) in the Soviet Union: Advances of (Nikolai Semenov), 185

L. *CASEI* (*C. diphtheriae* and): Nutritional Requirements of (F. W. Chattaway, Dr. F. C. Happold and M. Sandford), 559; (Dr. B. Lythgoe and Prof. A. R. Todd), 559
Laboratory: The Airman's, *review*, 292
Laboratory for Physical Geography at Cambridge (Prof. F. Debenham), 248
Laboratory Animals: Welfare of (Universities Federation for Animal Welfare), 723
Labour (Management and): Bibliography on (Sheffield City Libraries Research Bulletin No. 7), 557
Lakeland: The Birds of (Carlisle Natural History Society), 51
Lakeland Fauna: English, 51
Lambs in England in relation to Copper Feeding of Ewes during Pregnancy: Enzootic Ataxia or 'Swayback' of (Prof. T. Dalling), 29
Lamps (Fluorescent), their Photometric and Colour Rendering Properties and Measurement (G. T. Winch), 73
Land: An Unknown (Viscount Samuel), *review* by R. Brightman, 121
Land of Great Britain: Planning the, 623
Land (Derelict): Methods of Clearing, 78
Land Nemertean: A New (August Brinkmann, jun.), 253
Language: A World (Sir Richard Paget), 80
    A World Auxiliary, 89
Lankester (Ray) Fund: Dr. Shu-Ping Chu appointed by the trustees as investigator for 1943–44 on the Development of Marine Algæ, 362
Laplace Transform, The (David Vernon Widder), *review* by Prof. E. C. Titchmarsh, 66
Larch and Scots Pine Poles suitable for Transmission Lines, 194
Larvæ (Newt) in Brackish Water (Helen Spurway), 109; (Eric Hardy), 226
Latin American Culture: Great Britain and, 274
Lattice Dynamics: Density of Frequencies in (Prof. Max Born), 197; (Dr. Walter Ledermann), 197
Law of the Moving-Iron Electrical Instrument (Dr. G. F. Tagg), 423
Law and Morals, International (Prof. W. G. de Burgh), 648
    The Individualist Basis of (Prof. Morris Ginsberg), 648
Leaf Analysis as a Guide to Soil Fertility (Prof. H. Lundegårdh), 310
Leaf Movements (Autonomic) and Water-Balance in the Plant (C. V. Krishna Iyengar), 645
Leaf Palisade Tissue: Factors in the Production of (R. W. Watson), 113
Leafhopper Feeding Injury on Apparent Photosynthesis and Transpiration of Apple Leaves: Effects of (G. E. Marshall, N. F. Childers and H. W. Brody), 477
'Lectralevel' Floatless Liquid Level Control (Londex, Ltd.), 135
Leguminous Root Nodules: Anatomy of (Miss Helen L. Frazer), 141
Leicester: Air Pollution of (Dr. A. R. Meetham), 165
Lens Making: Prism and (F. Twyman), *review* by H. W. Lee, 458
Lens and Prism Manufacture: The Interferometer in (F. Twyman), 43
Lepidoptera (British): Distribution and Origin of (B. P. Beirne), 701
Leprosy: Epidemiology of (Dr. G. W. McCoy), 695
Leprosy by Ticks: Transmission of (Dr. H. Souza Aranjo), 337
Lettuce: Vernalization of (A. C. Simpson), 279
Library (Public) in Reconstruction, 317
Library System (Public) of Great Britain (L. R. McColvin), 317
Life Assurance Companies: The Mortality of Adult Males since the Middle of the Eighteenth Century as shown by the Experience of (Sir William P. Elderton and M. E. Ogborn), 329
Light: Increase in Toxicity of Stilbamidine Solution on Exposure to (Dr. H. J. Barber, R. Slack and E. Wien), 107
Light Effect in Chlorine under Electric Discharge—Influence of the Intensity and Frequency (Prof. S. S. Joshi and P. G. Deo), 561
Light, (Effect of Air Currents,) Humidity and Temperature on Slugs (Mrs. Barbara H. Dainton), 25
Light and Vision (Sir John Parsons), 638
Lighters: Mechanical (Sir Charles Boys), 336
Lightning: Protection of Structures against (J. F. Shipley), 638
Lightning in relation to Telephone Cables: Measurement of (J. J. Mahoney, jun.), 537
Lightning Currents: Magnitudes of (R. H. Golde), 421
Linkage of Physico-Chemical Processes in Biological Systems (Prof. E. J. Conway and E. O'Malley), 252
Liquid Level Control: Floatless (Londex, Ltd.), 135
Liquid State: H. L. Callendar and the Theory of the (Dr. R. S. Silver), 588
    Nature of the (Sir C. V. Raman), 478
Liquid Systems: Mechanism and Chemical Kinetics of Organic Reactions in (General Discussion held by the Faraday Society), *review*, 516
Literature relating to Constitutional Diagrams of Alloys: Bibliography of the (Compiled by Dr. J. L. Haughton), *review*, 600
Liver (Anoxæmic Changes in the) with regard to the 'High-Altitude Death' of Airmen (Dr. Peter Ladewig), 558
Liver (Mammalian): Urea Synthesis in (Dr. H. A. Krebs), 23; (Dr. S. J. Bach and S. Williamson), 23
Liver Vacuoles and Anoxæmia (Dr. O. A. Trowell), 730
Livestock Management and Public Health (Backs to the Land Club discussion on), 417
Lobsters (Crabs and): Density of (A. G. Lowndes), 336
Location of Industry (R. G. Glenday), 565
Loch Qouich: The Water Resources of (Capt. W. N. McClean), 528
Locust (Anti-) Campaign: An International (Dr. B. P. Uvarov), 41
Locusts and other Migratory Insects in India (Dr. A. D. Imms), 509; (Rao Bahadur Y. Ramchandra Rao), 509
Logic of Question and Answer (Prof. A. D. Ritchie), 498
Luminescence and Colour, 73
Luminescent Materials: The Chemical and Physical Properties of (Dr. J. W. Strange), 73
Luminosity a Mendelian Character in a Fungus (Ruth Macrae), 113
Lyell Fund (a moiety of the) of the Geological Society awarded to Dr. M. H. Hey and to Mr. F. A. Bannister, 164
Lyell Medal of the Geological Society awarded to Mr. D. N. Wadia, 164
Lysis of Red Blood Cells: Mechanism of (Lt.-Col. Brian Maegraith, Brig. G. M. Findlay and Major N. H. Martin), 252

MACHINERY of Government—Methods and Men, 1
Macnab (William) Medals for 1942 of the Institution of Chemical Engineers presented to Mr. J. H. Sharp and Mr. F. J. Wilkins, 418
Madrid: Observatorio Astronómico de, Anuario para 1943, *review*, 405
Magnesium (Dr. C. H. Desch), 692
    Production of (Prof. F. C. Thompson), 692
Magnetic Crack-Detection (G. B. Young), *review*, 378
Magnetization of Matter by Ultra-Violet Radiation (S. L. Martin and A. K. Connor), 167
Magnets about a Straight Conductor: A Variant o Maxwell's Experiment on the Movement of (H. E. Park), 697
Magnitogorsk: The Story of, *review* by Dr. David Williams, 516
Magnitudes of Lightning Currents (R. H. Golde), 421
Maize Seedling: Physiology of the (J. H. Kempton), 477
Makdougall-Brisbane Prize of the Royal Society of Edinburgh for 1938–1942 awarded to Sir William Wright Smith, 276
Making of an Engineer (A. Reyrolle and Co. Ltd.), *review* by Prof. Willis Jackson, 570
Making of a Research Worker (O. T. Faulkner), 332
Malaria (Indigenous) in Great Britain (Sir Arthur MacNalty), 440
Male Germ Cells of Dog and Cat (Developing): A Nuclear Ring in the (I. Zlotnik), 670
Malekula, Vao: Stone Men of (John Layard), *review* by Dr. H. G. Baynes, 711
Males (The Mortality of Adult) since the Middle of the Eighteenth Century as shown by the Experience of Life Assurance Companies (Sir William P. Elderton and M. E. Ogborn), 329
Malignant Tumour Cells: Origin of (Dr. P. C. Koller), 244
Mammalian Fauna of the Duchesne River (William B. Scott), 337
Mammalian Liver: Urea Synthesis in (Dr. H. A. Krebs), 23; (Dr. S. J. Bach and S. Williamson), 23
Mammals (British) in War-time, 247
Man: Seasonal Rhythms in, *review* by Prof. W. E. LeGros Clark, 66
Man (Early) in Ireland: Nature and, *review* by C. F. C. Hawkes, 376
Man (Modern): Archæology and, *review* by M. C. Burkitt, 515
Man-Carrying Aeroplane: The First, 192
Management and Labour: Bibliography on (Sheffield City Libraries Research Bulletin No. 7), 557
Manpower, Vol. 1, No. 1, 704
Manpower Survey of South Africa: A National (E. H. Cluver, E. Jokl and T. W. de Jongh), 704
Manufacturing Wooden Implements by Simple Stone Tools: An Unrecorded Method of (C. B. Mountford), 56
Map Construction from Aerial Photographs (Dr. G. D. Hobson), 588

Marine Algæ in Subantarctic and Antarctic Waters : Communities of (C. Skottsberg), 26
Marvels of the Vertebrate Eye, *review* by Prof. H. E. Roaf, 236
Mass Observation of the People, *review* by Lieut. T. H. Hawkins, 235
Materialism (Physical) : The New Physics and (London and Home Counties Branch of the Institute of Physics, the Aristotelian Society and the Mind Association symposium on), 686
Materialism, (Physics,) and Free Will (Prof. L. Susan Stebbing), 686
Materials (Raw) : Control of, 452
Maternal and Child Welfare in Venezuela (Dr. Pastor Oropeza), 221
Mathematical Applications : A Source Book of (National Council of Teachers of Mathematics, Seventeenth Yearbook), *review* by Dr. W. G. Bickley, 626
Mathematics, its Magic and Mastery (Aaron Bakst), *review*, 265
Mathematics (Elementary) : Applications of, *review* by Dr. W. G. Bickley, 626
Mathematics (Engineering) : Relaxation Methods in, 723
Matter : The Extreme Properties of (Sir Charles Darwin), 237
Matter by Ultra-Violet Radiation : Magnetization of (S. L. Martin and A. K. Connor), 167
Matter (Terrestrial) and the Uranium/Lead Ratio : The 'Age' of (F. F. Koczy), 24
Matto Grosso (Western) : Natives of Bolivia and (Alfred Métraux), 701
Maxwell's Experiment on the Movement of Magnets about a Straight Conductor : A Variant of (H. E. Park), 697
Mayer (Charles L.) Awards for Animal Cell Growth Research, 19
  First prize awarded to Prof. Charles B. Huggins, 637
Mayflies : Keys to the British Species of Ephemeroptera or (D. E. Kimmins), 112
Measurement of Lightning in relation to Telephone Cables (J. J. Mahoney, jun.), 537
Measurement of Short Electric Wave-lengths, 313
Measurements (Wavelength) of Decimetric, Centimetric and Millimetric Waves (A. G. Clavier), 313
Mechanical Lighters (Sir Charles Boys), 336
Mechanism of Biological Action of Vitamin K and its Synthetic Analogues (Prof. M. M. Shemiakin, L. A. Schukina and J. B. Shvezov), 585
Mechanism of the Electric Spark (Prof. Leonard B. Loeb and John M. Meek, *review* by Dr. T. E. Allibone, 178
Mechanism of Lysis of Red Blood Cells (Lt.-Col. Brian Maegraith, Brig. G. M. Findlay and Major N. H. Martin), 252
Mechanism and Chemical Kinetics of Organic Reactions in Liquid Systems (General Discussion held by the Faraday Society), *review*, 516
Medical Radiology : The Physical Basis of, *review* by Prof. F. L. Hopwood, 348
Medical Schools : British and Viennese, *review* by Dr. J. D. Rolleston, 461
Medical Sciences : Workers in the (Association of Scientific Workers conference on), 145
Medical Services in Argentina (Dr. Hugo J. D'Amato), 135
Medical Services (Factory) and Industrial Diseases : Week-end course on (London School of Hygiene and Tropical Diseases), 106
Medical Work : Indirect Radiography as Applied to (Miss K. C. Clark), 718
Medicine for Philosophers, *review* by Prof. E. A. Milne, 62
Medicine : War and (Dr. Henry E. Sigerist), 668
Medicine (Army) : Progress of, *review* by Major J. Marshall, 627
Medicine (British) and the Vienna School (Dr. Max Neuburger), *review* by Dr. J. D. Rolleston, 461
Medico-Dental History of Cloves (Dr. Eugene J. Molnar), 194
Medico-Legal Blood Group Determination (Dr. David Harley), *review* by Dr. H. S. Holden, 487
Medusæ : Water Content of (A. G. Lowndes), 226
Medusæ, Water Content of : Sexuality in a Planarian (Dr. Libbie H. Hyman), 140
Melanconis, Pseudovalsa, Prosthecium and Titania : A Revision of (Lewis E. Wehmeyer), *review* by E. W. Mason, 208
Melchett Medal for 1943 of the Institute of Fuel awarded to Dr. E. S. Grumell, 722
Men (Stone) of Malekula, Vao (John Layard), *review* by Dr. H. G. Baynes, 711
Mendelian Character in a Fungus : Luminosity a (Ruth Macrae), 113
Mental Attitudes in Time of War (British Psychological Society symposium on), 684
Mercurial Preparation : Apparent Stimulative Effect on Mould Growth of a (Dr. Madge E. Robertson), 365
Mercury on Nov. 11–12, 1940 : Transit of (G. M. Clemence and G. C. Whittaker), 57
Metabolism (Calcium) and Nutrition Problems (Dr. J. D. Robertson), 379
Metabolism (Phosphorus) in Moulds (Dr. T. Mann), 619
Metallic Films : Frictional Properties of (Dr. Robert Schnurmann), 420 ; (Dr. T. P. Hughes), 533
Metallographical Research in Sweden, 529
Metallurgical Abstracts (General and Non-Ferrous), Vol. 8, 1941, edited by N. B. Vaughan, *review*, 265
Metals : A New Method of Etching on (Griffin and Tatlock, Ltd.), 361
  X-Ray Evidence of the Nature of Cold Work in (A. R. Stokes, K. J. Pascoe and Dr. H. Lipson), 137
Metals (Cold-worked) : New X-Ray Evidence on the Nature of the Structural Changes in (Dr. W. A. Wood), 585
Metals (Non-ferrous) : Crack Detection in, 555
Metaphosphoric Acid Extracts : Stability of Ascorbic Acid in (L. W. Mapson and C. A. Mawson), 222
Meteor (The Portland) and Resulting Meteorite (J. Hugh Pruett), 192
Meteors Seen in the United States, 192
Methanol (Ethanol-) at 40° : The System (A. C. Morris, L. T. Munn and G. Anderson), 142
Methods of Clearing Derelict Land, 78
α-Methyl Stilbene on the Insulin Content of the Pancreas of the Rabbit : Effect of Hexoestrol and of (Dr. Mervyn Griffiths), 82
Methylation (Nuclear) of Aromatic Amines and Phenolic Substances : A New Method of (Miss M. G. Barclay, Dr. A. Burawoy and G. H. Thomson), 615
Mexico : Benioff Vertical-Component Seismograph to be installed at the National Astrophysical Observatory, Tonantzintla, 530
Mickle (William Julius) fellowship of the University of London awarded to Prof. E. C. Dodds, 275
Micro-Organisms in Nutrition (Food Yeast) : Value of (Dr. A. C. Thaysen), 406
Micro-Organisms : Histochemistry of the Gram-staining Reaction for (Dr. H. Henry and Dr. M. Stacey), 671
Microscope Observations of the Crushing of Coal (Dr. R. G. H. B. Boddy), 54
Microscopic (Electron-) Examination of Tissues (Fritiof Sjöstrand), 725
Midlands (West) : Reconstruction in Birmingham and the (Councillor Paul Cadbury), 667
Milk Testing (National) and Advisory Scheme (Prof. H. D. Kay and Dr. J. G. Davis), 114
Mine Pumping : Application of Electricity in (G. B. Alvey and N. Tetlow), 79
Mineral Resources : India's (Sir Lewis Fermor), 689
  Suggestions for the Future Development of (Dr. J. A. Dunn), 689
Mineral (Chemical and) Products : Control of, 455 ; (Sir Robert Robinson), 562
Minerals (Vitamins and), for Everyone (Alida Frances Pattee), *review*, 572
Minimum Human Requirements and the Beveridge Report (Sir Joseph Barcroft, Prof. Stanley Davidson, Sir F. Gowland Hopkins, Lord Horder, Prof. Julian Huxley, Prof. J. M. Mackintosh, Sir Charles Martin, Sir Robert McCarrison, Lord Moran of Manton, B. S. Rowntree, Prof. J. C. Spence and Prof. W. H. Wynn), 422
Mitotic Activity of the Mouse Parathyroid Gland (C. L. Foster), 277
Modern Fruit Production (Prof. Joseph Harvey Gourley and Prof. Freeman Smith Howlett), *review* by Dr. R. G. Hatton, 92
Modern Industry in the Netherlands East Indies (Dr. P. H. W. Sitsen), 468
Molecular Films, the Cyclotron and the New Biology (Hugh Stott Taylor, Ernest O. Lawrence and Irving Langmuir), *review* by Prof. J. A. Crowther, 67
Molecular Structure of Ozone (W. Shand and R. A. Spurr), 645 ; (C. P. Smyth and G. L. Lewis), 645
Molecular Tinkering and Tailoring, *review* by Prof. John Read, 488
Molecules (Long-Chain) in Aqueous Urea Solution (Dr. R. E. D. Clark), 642
Molybdenosis of Farm Animals : 'Teart' of Somerset, a (W. S. Ferguson), 30
Morals : International Law and (Prof. W. G. de Burgh), 648
Morals (International Law and) : The Individualist Basis of (Prof. Morris Ginsberg), 648
Morphine-like Properties of Diphenylethylamine and related Compounds (Prof. E. C. Dodds, W. Lawson and P. C. Williams), 614
Morphogenesis: Biochemistry and (Dr. Joseph Needham), *review* by Sir Joseph Barcroft, 402
Morphology (Comparative) of the Algæ (F. E. Fritsch), 112
Mortality of Adult Males since the Middle of the Eighteenth Century as shown by the Experience of Life Assurance Companies (Sir William P. Elderton and M. E. Ogborn), 329
Mortality (Infant) in the United States (Herbert J. Sommers), 193
Mortality (Development and) of *Tribolium destructor* Uyttenboorgaart (Coleoptera, Tenebrionidæ) : Effect of Parental Feeding on the Rate of (J. M. Reynolds), 55
Mortality-Rates in the United States : Changes in (Harold F. Dorn), 639
Mould Growth (Apparent Stimulative Effect on) of a Mercurial Preparation (Dr. Madge E. Robertson), 365
Moulds : Phosphorus Metabolism in (Dr. T. Mann), 619
Moulton Medal for 1942 of the Institution of Chemical Engineers presented to Mr. W. K. Hutchinson and Dr. E. Spivey, 418
Moulton Medal and Award (Junior) for 1942 of the Institution of Chemical Engineers presented to Dr. S. H. Wade, 418
Mouse Parathyroid Gland : Mitotic Activity of the (C. L. Foster), 277
Moving-Iron Electrical Instrument : Law of the (Dr. G. F. Tagg), 423
Murchison Fund of the Geological Society awarded to Mr. A. G. Davis, 164
Murchison Medal of the Geological Society awarded to Prof. A. Brammall, 164
Murine Typhus in Bogotá (Dr. Luis Patino-Camargo), 445
Murray Hill Laboratory of Bell Telephone Laboratories (Franklin L. Hunt), 674
Muscle (Denervated) : Onset of Fibrillation in (Dr. G. Weddell, Dr. B. Feinstein and R. E. Pattle), 449
Muscles (Crustacean) : Innervation of (William Holmes), 531
Muscles (Bones and) : Influence of a Prolonged Partial Deficiency of Vitamin C on the Recovery of Guinea Pigs from Injury to (Dr. E. Kodicek and Dr. P. D. F. Murray), 395
Musculature of the Labrum, Labium and Pharyngeal Region of Adult and Immature Coleoptera (C. K. Dorsey), 644
Museum : Geology in the (Dr. F. J. North, C. F. Davidson and Lieut. W. E. Swinton), *review*, 6
Museum Presentation of Geology, *review*, 6
Museums and Education (G. F. Westcott), 160
Mutation (Kaleidoscopic): Evolution in Plants by (Dr. J. C. Willis), 283
Mutations in *Cicer arietinum* (R. B. Ekboto), 283
Mycological Nomenclature (Miss E. M. Wakefield, E. W. Mason, G. R. Bisby and J. Ramsbottom), 303
Myrmecophilous Woodlouse, A : (Horace Donisthorpe), 675 ; (Prof. J. L. Brooks), 675
Mythology of Cancer Research (Prof. E. L. Kennaway), 302

NAPHTHACENE : Fluorescence of Anthracene in Presence of (S. C. Ganguly), 673
National Economy : Coal Utilization Research and the, 709
National Expenditure, Select Committee on : Sixteenth report of the, 1 ; Third report of the, 200 ; Eighth report of the, 723
National Flour and Bread : Third Report, 629
National Gallery in War-time (F. Ian G. Rawlins), 123
National Manpower Survey of South Africa (E. H. Cluver, E. Jokl and T. W. de Jongh), 704
National Milk Testing and Advisory Scheme (Prof. H. D. Kay and Dr. J. G. Davis), 114
National Scheme for Holiday Centres, 86
National Vigour and the Temperate Zone, *review* by Prof. H. J. Fleure, 431
Nations : Climate and the Energy of (S. F. Markham), *review* by Prof. H. J. Fleure, 431
Natives of Bolivia and Western Matto Grosso (Alfred Métraux), 701
Natural Classification of the Steroids : An Attempt at a (Prof. Hans Selye), 662

Natural History : North African, 20
Natural Philosophy : The Fundamental Concepts of (Prof. E. A. Milne), 530
Natural and Synthetic High Polymers (Prof. Kurt H. Meyer, translated by Dr. L. E. R. Picken), *review* by Prof. H. W. Melville, 682
Nature of Entropy (Ian D. Campbell), 138 ; (Prof. H. S. Allen), 225 ; (Sir James Swinburne), 335 ; (M. W. Thring), 672
Nature of Peptones (Prof. P. J. Fodor, S. Kuk, and J. Diamante-Lichtenstein), 280
Nature of the Structural Changes in Cold-worked Metals : New X-Ray Evidence on the (Dr. W. A. Wood), 585
Nature Observation Scheme : An Army, 668
Nature Preservation in Post-War Reconstruction (Society for the Promotion of Nature Reserves conference on), 707
Nature Reserve at Oxford, 328
Nature Reserves, 707
Nature and Early Man in Ireland, *review* by C. F. C. Hawkes, 376
Navigation : Air (Lieut.-Comdr. P. V. H. Weems), British Empire edition, revised and edited by Arthur J. Hughes and P. F. Everitt, second edition, *review*, 572
Nebulæ : Diameters of Extragalactic (Dr. H. Shapley), 57
Necessity (Chance, Freewill, and) in the Scientific Conception of the Universe (Prof. E. T. Whittaker), 612
Nemertean : A New Land (August Brinkmann, iun.), 253
Nephridia of Earthworms (K. N. Bahl), 112
Ness Basin, 1929–1942 : River Flow Records of the (Capt. W. N. McClean), 528
Netherlands East Indies : Modern Industry in the (Dr. P. H. W. Sitsen), 468
Netherlands Indies : Research in the (Dr. P. Honig), 242
'New Deal' as a Social Philosophy (Prof. D. Mitrany), 134
New Mexico (Eastern) : Archæological and Geological Investigations in the San Jon District (F. H. Roberts), 282
New Physics and Physical Materialism (London and Home Counties Branch of the Institute of Physics, the Aristotelian Society and Mind Association symposium on), 686
New Zealand : Earthquakes registered during November, 331 ; during January, 694
News and Views from the Scientific Front (Sir Richard Gregory), 517
Newt Larvæ in Brackish Water (Helen Spurway), 109 ; (Eric Hardy), 226
Newton : Polish Homage to, 133
Newton and the Apple (Prof. E. N. da C. Andrade), 84
Newton Scholarships for Soviet University Students, 106
Newton's Chemical Philosophy (Dr. D. McKie), 417
Newton's Library : Sale of a portion by Henry Sotheran, Ltd., 416
  Purchase of the residue by the Pilgrim Trust, 446
Newton, (Aristotle), Einstein (Prof. E. T. Whittaker), 59
Newtonianism and Scholasticism, 59
Nicotine in Plants Grafted on Tobacco ; Formation of (A. Shmuck, A. Smirnov and G. Ilyin), 338
Nitre Formation in Deserts : Role of Blue-Green Algæ in (S. V. Odintzova), 701
Nitric Oxide : Quenching of Fluorescence by (Dr. H. Weil-Malherbe and Dr. Joseph Weiss), 449
Nitrogen : A New Band Sprectum Associated with (Dr. A. G. Gaydon), 167
Nitrogen Status of Soils and the Origin of Soil Nitrogen : Improvement of the (Prof. N. R. Dhar), 590
Nitrosobenzene (Phenyl Hydroxylamine and) : Reactions of Hæmoglobin and its Derivatives with (Prof. D. Keilin and Dr. E. F. Hartree), 390
Nomenclature : Mycological (Miss E. M. Wakefield, E. W. Mason, G. R. Bisby and J. Ramsbottom), 303
Non-Euclidean Geometry (Prof. H. S. M. Coxeter), *review* by Prof. H. T. H. Piaggio, 94
Non-Singular Cubic Surfaces (B. Segre), *review* by Dr. H. F. Baker, 39
Norfolk Coast : A New Palæolithic Industry from the (D. F. W. Baden-Powell and J. Reid Moir), 26
Norfolk Island : Insect Fauna of (C. N. Hawkins), 141
North Pole : Obscuration around the (E. G. Martin), 702
Nottingham Open Forum, 18
Novelda-Monforte : Earthquake on January 21, 584
Nuclear Methylation of Aromatic Amines and Phenolic Substances : A New Method of (Miss M. G. Barclay, Dr. A. Burawoy and G. H. Thomson), 615
Nuclear Ring in the Developing Male Germ Cells of Dog and Cat (I. Zlotnik), 670
Nucleoli in *Agropyron repens*, Beauv. (Dr. B. C. Sharman), 170
Nucleosides (Purine) : Configuration of (Prof. J. M. Gulland, G. R. Barker and D. O. Jordan), 109
Numbers : Guide to Tables in the Theory of (Derrick Henry Lehmer), *review* by Prof. L. J. Mordell, 64
Numbers, Numbers, Numbers, *review* by Prof. L. J. Mordell, 64
Nursery Schools : War-time (Mrs. F. A. Ogden), 100
Nutrition : Rumford's Contributions to (A. F. Dufton), 199
Nutrition in Infancy (Nutrition Society conference on), 530, 687
Nutrition in Pregnancy (Nutrition Society conference on), 321
Nutrition (Food Yeast) ; Value of Micro-Organisms in (Dr. A. C. Thaysen), 406
Nutrition Problems : Calcium Metabolism and (Dr. J. D. Robertson), 379
Nutrition Surveys : Formation of a Committee on (Nutrition Society), 444
Nutrition (Human) : Fluorine in (Dr. M. M. Murray, Dr. D. C. Wilson and F. H. Kemp), 30
Nutritional Needs (World) : Agriculture and (F. le Gros Clark), 274 ; (Prof. J. R. Marrack), 509
Nutritional Requirements of *C. diphtheriae* and *L. Casei* (F. W. Chattaway, Dr. G. C. Happold and M. Sandford), 559 ; (Dr. B. Lythgoe and Prof. A. R. Todd), 559

OBSCURATION around the North Pole (E. G. Martin), 702
Obscured Regions in the Greenwich Astrographic Zone (E. G. Martin), 27
Observation (Mass) of the People, *review* by Lieut. T. H. Hawkins, 235
Observations (Microscope) of the Crushing of Coal (Dr. R. G. H. B. Boddy), 54
Observatorio Astronómico de Madrid : Anuario para 1943, *review*, 405
Offenders (Young), an Enquiry into Juvenile Delinquency (A. M. Carr-Saunders, Hermann Mannheim and E. C. Rhodes), *review* by Prof. Cyril Burt, 291
Oil Well Drainage (Dr. Stanley C. Herold), *review* by H. B. Milner, 38
Oils (Fish Liver) ; The Spectrophotometric Estimation of Vitamin A in (J. I. M. Jones and R. T. M. Haines), 57
Oligogenes : Polygenes and (Dr. C. H. Waddington), 394
Onion (Wild) : Eradication of (J. R. Tinney), 300
Ontario : Age Determinations of Intrusive Rocks (H. C. Horwood and N. B. Keevil), 701
Optical Dispersion for Coals (C. G. Cannon and Dr. W. H. George), 225
Optically Active Arsonium Salt, An (Dr. F. G. Mann and F. G. Holliman), 474
Orbital Motion in the Visual Double Star 61 Cygni (K. Aa. Strand), 283
Orbital Motion and Measurements for Parallax (J. Jackson), 478 ; (Miss Vinter Hansen), 478
Order and Chaos in the World of Atoms (B. C. Saunders and Dr. R. E. D. Clark), *review* by Prof. John Read, 488
Organic Chemical Methods : Recent Advances in (Dr. E. R. H. Jones), 564
Organic Compounds : Supply of (L. Light and Co. Ltd.), 669
Organic Reactions in Liquid Systems : Mechanism and Chemical Kinetics of (General Discussion held by the Faraday Society), *review*, 516
Organisation of Science : in Great Britain, 206
  in the U.S.A., 207
  in the U.S.S.R., 207
Organization of American Scientists for the War (Pilgrim Trust Lecture of the Royal Society by Dr. Karl T. Compton), 362, 601
Origin of British Lepidoptera : Distribution and (B. P. Beirne), 701
Origin of Cosmic Rays (Dr. R. A. Millikan, Dr. H. V. Neher and Dr. W. H. Pickering), 663
Origin of Soil Nitrogen : Improvement of the Nitrogen Status of Soils and the (Prof. N. R. Dhar), 590
Origin of Species : Systematics and the (Ernst Mayr), *review* by Dr. Julian Huxley, 347
Osmotic Pressure of Biological Fluids : Determination of the (Dr. R. Aschaffenburg), 169
Oterma Comet (1942 *f*): Orbit computed by Dr. F. L. Whipple, 362
Overhead Lines (Single-Circuit) up to 33 kV. : Standardization in Great Britain of (H. Willott Taylor and K. L. May), 445
Ovifak : Great Iron Boulder from (H. Löfquist and C. Benedicks), 26
Oxford : Czechoslovak Degrees at, 274
  Czechoslovak Medical Students at (Prof. John Read), 366 ; (Dr. R. Fitzgibbon Young), 450
  History of the Botanic Garden, 367
  Nature Reserve at, 328
Oxidation of Ascorbic Acid in Tea (G. A. Snow and S. S. Zilva), 112
Oxidation (Electrolytic) of Formaldehyde (A. Hickling and F. Rodwell), 702
Ozone : Molecular Structure of (W. Shand and R. A. Spurr), 645 ; (C. P. Smyth and G. L. Lewis), 645
Oxygen : Heavy (E. R. S. Winter and H. V. A. Briscoe), 142

PACIFIC Ocean (North) : Earthquake in the Aleutian Islands Archipelago on January 27, 530
Painting Materials, a Short Encyclopedia (Rutherford J. Gettins and George L. Stout), *review* by F. Ian G. Rawlins, 262
Palæolithic Industry (New) from the Norfolk Coast (D. F. W. Baden-Powell and J. Reid Moir), 26
Palisade Tissue (Leaf) : Factors in the Production of (R. W. Watson), 113
Pamphlets in War-time, 76
Pan-American Congress of Endocrinology to be held at Buenos Aires in July, 249
Pan-American Sanitary Congress, 303
Pancreas of the Rabbit : Effect of Hexoestrol and of *a*-Methyl Stilbene on the Insulin Content of the (Dr. Mervyn Griffiths), 82
Pantothenic Acid in Tissue Growth (H. McIlwain), 56
Parallax : Orbital Motion and Measurements for (J. Jackson), 478 ; (Miss Vinter Hansen), 478
Parasite (Host-) Relationships of Barley and *Helminthosporium sativum* P., K. and B. (H. W. Mead), 369
Parasitology : Introduction to (Prof. A. S. Pearse), *review*, 264
Parathyroid Gland (Mouse) ; Mitotic Activity of the (C. L. Foster), 277
Paraxanthine as a Natural Antithyroid Substance (Dr. G. S. Carter, Dr. F. G. Mann, J. Harley-Mason and G. N. Jenkins), 728
Parental Feeding (Effect of) on the Rate of Development and Mortality of *Tribolium destructor* Uyttenboorgaart (Coleoptera, Tenebrionidae) (J. M. Reynolds), 55
Paris : Health in, 530
Parliament : Science and, 156
'Pasmo' Disease of Flax (John Colhoun and Arthur E. Muskett), 223
Pathology and Treatment of War Wounds (Sir Almroth E. Wright), *review* by Prof. A. A. Miles, 209
Peace : Geology and Geologists in the War and the (Prof. H. H. Read), 119
Pebbles : Shape of (Lord Rayleigh), 338
Penicillamine, a Characteristic Degradation Product of Penicillin (E. P. Abraham, E. Chain, W. Baker and Sir Robert Robinson), 107
Penicillin : Penillic Acid, an Optically Active Acid from (W. M. Duffin and Dr. S. Smith), 251
Penicillium on the Cut Surfaces of Certain Vegetables : Development of (W. A. R. Dillon Weston and R. Eric Taylor), 54
Penillic Acid, an Optically Active Acid from Penicillin (W. M. Duffin and Dr. S. Smith), 251
People : The Pub and the, a Worktown Study (Mass Observation), *review* by Lieut. T. H. Hawkins, 235
People's Commissar for Education in the U.S.S.R. : Institution of Newton scholarships for Soviet university students, 106
Peoples of the Philippines (Herbert W. Krieger), 445
Peoples of the Soviet Union (Dr. Aleš Hrdlička), 20
Peptones : Nature of (Prof. P. J. Fodor, S. Kuk and J. Diamante-Lichtenstein), 280
Periodicals : Conservation of Scientific and Technical, 512
Periodicals (Russian Scientific and Technical) in Great Britain, 77
Periods (Half-Value) : Determination of (A. G. Ward), 338
Perithecia in Banana Leaf Spot Disease : Soil Conditions affecting Production of (R. Leach), 199
Perkin Medal of the American Section of the Society of Chemical Industry awarded to Dr. Robert E. Wilson, 221

Personality, Disease and the Social System (P. J. Kloppers), 705
Peru : Tuberculosis in (Dr. Ricardo Martinez), 557
  Control of Venereal Diseases in, 79
Pests : Chemical Attack upon (Dr. R. E. Slade), 649
pH Measurements : A Modified Calomel Cell for (A. D. Elmsly Lauchlan and Dr. James E. Page), 84
Phagocytosis in the Appendix of the Rabbit (Frank Baker and John Enticknap), 532
Phenolic Substances : A New Method of Nuclear Methylation of Aromatic Amines and (Miss M. G. Barclay, Dr. A. Burawoy and G. H. Thomson), 615
Phenological Report for 1942 (Royal Meteorological Society), 418
Phenyl Hydroxylamine and Nitrosobenzene : Reactions of Hæmoglobin and its Derivatives with (Prof. D. Keilin and Dr. E. F. Hartree), 390
Philippines : Peoples of the (Herbert W. Krieger), 445
Philosophers : Medicine for, *review* by Prof. E. A. Milne, 62
Philosophy : Physics and (Sir James Jeans), *review* by Prof. E. A. Milne, 62
Philosophy (Social) : The 'New Deal' as a (Prof. D. Mitrany), 134
Phoenix, a Summary of the Inescapable Conditions of World Reorganization (H. G. Wells), *review* by Lord Horder, 374
Phosphorus during Sewage Purification : Loss of (Dr. S. H. Jenkins and W. T. Lockett), 306
Phosphorus Metabolism in Moulds (Dr. T. Mann), 619
Phosphorus Pentachloride : Crystal Structure of, 27
Photo-elastic Stress Patterns : The Photography of (H. McGregor Ross), 720
Photographers : Scientific and Industrial, 501
Photographic Infra-Red : Flame Spectra in the (Dr. A. G. Gaydon), 645
Photographic Photometry : Star Magnitudes and Image Diameters in (D. L. Edwards), 31
Photographic Record of the Linnean Society Collections (J. R. Norman), 105
Photographs (Aerial) : Map Construction from (Dr. G. D. Hobson), 588
Photography : Applied (Prof. J. Yule Bogue), 718
  Towards Atomic (C. W. Bunn), 506
  of Photo-elastic Stress Patterns (H. McGregor Ross), 720
  in Science and Industry (Herbert E. Zerkowsky), 501
  as a Scientific Instrument, 718
Photography (Crystal) with Divergent X-Rays (Dr. K. Lonsdale), 52
Photometry (Photographic) : Star Magnitudes and Image Diameters in (D. L. Edwards), 31
Photomicrography : Aspects of (Scientific and Technical Group of the Royal Photographic Society symposium on), 367
Photosynthesis and Transpiration (Apparent) of Apple Leaves : Effects of Leafhopper Feeding Injury on (G. E. Marshall, N. F. Childers and H. W. Brody), 477
Phylogeny : Avian (Percy R. Lowe), 112
Physical Basis of Medical Radiology, *review* by Prof. F. L. Hopwood, 348
Physical Education in Great Britain and the Dominions (Miss P. Spafford), 193
Physical Fitness of School Children in South Africa (Prof. D. Burns), 704
Physical Materialism : The New Physics and (London and Home Counties Branch of the Institute of Physics, the Aristotelian Society and the Mind Association symposium on), 686
Physical Properties (Chemical and) of Luminescent Materials (Dr. J. W. Strange), 73
Physicist ? : Engineer or (Dr. Percy Dunsheath), 134
Physicists : Report to (American Institute of Physics), 397
Physico-Chemical Processes in Biological Systems : Linkage of (Prof. E. J. Conway and E. O'Malley), 252
Physics : Fundamental Particles of (Dr. H. J. Bhabha), 628
  Radiologic (Charles Weyl, S. Reid Warren, Jr., and Dallett B. O'Neill), *review* by Prof. F. L. Hopwood, 348
  Recent Advances in the Theory of the Fundamental Particles of (Sir Ralph Fowler), 628
  (Theoretical) in the U.S.S.R. during the Past Twenty-five Years (Prof. Dmitry Ivanenko), 293
Physics (The New) and Physical Materialism (London and Home Counties Branch of the Institute of Physics, the Aristotelian Society and the Mind Association symposium on), 686
Physics and Philosophy (Sir James Jeans), *review* by Prof. E. A. Milne, 62
Physics, Materialism, and Free Will (Prof. L. Susan Stebbing), 686
Physiological Action of Acetic Acid in Living Tissues (Sir Joseph Barcroft, Rachel McAnally and Andrew Phillipson), 304
Physiological Function and Enzyme Systems : Copper, Zinc and other Trace Elements in relation to (Dr. H. Mann and Prof. D. Keilin), 28
Physiological Theory of Colour Perception (Prof. Ragnar Granit), 11
Physiologists (Russian) : Greetings from, 79
Physiology of Colour Vision (E. N. Willmer), 213, 632; (Dr. F. W. Edridge-Green), 422 ; (Prof. H. Hartridge), 422 ; (K. J. W. Craik), 727
Physiology of the Grass Seedling (R. L. Weintraub and E. D. McAlister), 477
Physiology of the Maize Seedling (J. H. Kempton), 477
Phytoplankton Periodicity in Antarctic Surface Waters (T. John Hart), 647
Pico della Mirandola and the Scholastic Tradition (Avery Dulles), *review* by the Rev. J. C. Hardwick, 710
Pigeon (Wood) Investigation : Report of the Edward Grey Institute for 1942, 302
Pigments (Fluorescent) in Colour Printing : The Use of (F. W. Coppin), 73
Pilgrim Trust Lecture of the Royal Society (Dr. Karl T. Compton), 362, 601
Pine (Larch and Scots) Poles suitable for Transmission Lines, 194
'Pining' (Sheep) in Britain (W. Lyle Stewart), 29
Pirotechnia of Vannoccio Biringuccio (translated from the Italian by Cyril Stanley Smith and Martha Teach Gnudi), *review* by Prof. John Read, 569
Pituitary (Posterior Lobe) Extracts : Renal Excretion of (Dr. H. Heller), 502
Planarian : Sexuality in a (Dr. Libbie H. Hyman), 140
Planetary Systems : Formation of (B. M. Peek), 200
Planned Feeding in Great Britain : Four Years of (Dr. Magnus Pyke), 658
Planning : Political and Economic, 372
Planning for Holidays (P E P Broadsheet No. 194), 86
Planning the Land of Great Britain, 623
Planning Post-War Britain, 311
Planning of Science in War and in Peace (Association of Scientific Workers conference on), 20, 152, 153, 203
Planning (Post-War) : Geology in (Prof. P. G. H. Boswell), 493
Planning (Scientific) : The Basis of (Prof. H. Levy), 157
Planning (Soviet) in War-time (P E P Broadsheet), 50
Planning and Reconstruction : Post-war (Institution of Municipal and County Engineers), 311
Plant : Autonomic Leaf Movements and Water-Balance in the (C. V. Krishna Iyengar), 645
Plants, Indian Silicified : I, *Azolla intertrappea* Sahni and H. S. Rao (B. Sahni), 338
Plants: The Reproductive Capacity of (Prof. E. J. Salisbury), *review*, 319
Plants by Kaleidoscopic Mutation: Evolution in (Dr. J. C. Willis), 283
Plants Grafted on Tobacco : Formation of Nicotine in (A. Shmuck, A. Smirnov and G. Ilyin), 338
Plants (Arctic) : Early Collections of (Dr. N. Polunin), 645
Plants (Chinese) to Great Britain : Introduction of, 136
Plants (Cultivated) : Effects of Altitude on the Chemical Composition of (S. O. Grebinsky), 338
Plants (Virus-infected) : Cytoplasmic Inclusions in (B. Kassanis and F. M. L. Sheffield), 337
Plants and Animals : Significance of Trace Elements in relation to Diseases of (Dr. H. H. Green), 28
Plasma (Urine and) from Normal and Hypertensive Subjects : Pressor Substances in (Prof. U. S. v. Euler and T. Sjöstrand), 168
Plastic-elastic Scale : The Position of the Rubber-like State on the (R. C. Seymour and J. M. Buist), 563
Plastics (Organic) : Recording Plastometer for (F. J. Biondi), 142
Plastometer (Recording) for Organic Plastics (F. J. Biondi), 142
Pleistocene (A Middle) Discovery in the Anglo-Egyptian Sudan (G. Andrew and A. J. Arkell), 226 ; (E. J. Wayland), 334
Plywood Containers, 731, 732
Pneumonia (Atypical) : Development of Cold Agglutinins in (Lt.-Col. Joseph C. Turner), 419
Polarization (Circular) of Ionospherically Reflected Radio Waves : A Simple Method of Demonstrating the (Sir Edward V. Appleton), 250
Poles (Larch and Scots Pine) suitable for Transmission Lines, 194
Poles (Telephone) : 'Greensalt' Preservative for (C. M. Hill), 302
Policy : Colonial, 219
Polish Homage to Newton, 133
Polish Science and Learning, No. 2, 529
Political Institutions : British (Prof. Andrew Browning), *review* by R. Brightman, 543
Political and Economic Planning, 372
Politics in the South Seas : Economics and, *review* by Dr. Lucy Mair, 625
Politics : The Body as a Guide to (Dr. W. B. Cannon), 77
Pollen (Atmospheric) : A Census of (H. A. Hyde and Dr. D. A. Williams), 82
Pollution : Atmospheric (Dr. G. M. B. Dobson and Dr. A. R. Meetham), 324
  (Air) of Leicester (Dr. A. R. Meetham), 165
Polygenes : The Concept of (A. C. Fabergé), 643
  in Development (Dr. K. Mather), 560
Polygenes and Oligogenes (Dr. C. H. Waddington), 394
Polygenic Balance in the Canalization of Development (Dr. K. Mather), 68
Polymers (High) : Natural and Synthetic (Prof. Kurt H. Meyer, translated by Dr. L. E. R. Picken), *review* by Prof. H. W. Melville, 682
Polynesians—Explorers of the Pacific (J. E. Weckler, Jr.), *review* by Mrs. K. Rishbeth, 599
Population of Bristol (H. A. Shannon and E. Grebenik), *review* by D. Caradog Jones, 514
Populations (Wild) : Studies of (Dr. C. B. Williams), 71
Porphyrin by Autolysing Yeast and by Yeast Press Juice : Formation of (Dr. C. Rimington), 393
Porpoise (A Rare) of the South Atlantic, *Phocaena dioptrica* (Lahille 1912) (J. E. Hamilton), 647
Port (Seamen's Welfare in) : Welfare Outside the Factory and (Report issued by the Ministry of Labour and National Service), 116
Portland Meteor and Resulting Meteorite (J. Hugh Pruett), 192
Portuguese Anthropological Studies, 300
Post-War Agricultural Education (Ronald Ede), 673
  Report of the Committee on, 539
Post-War Air Transport (Viscount Cranborne), 360
Post-War Britain : Planning, 311
Post-War Civil Aviation in Great Britain, 175
Post-War Commercial Air Transport (F. C. R. Jaques), 247
Post-War Planning : Geology in (Prof. P. G. H. Boswell), 493
Post-War Planning of Psychology in the United States, 677
Post-War Planning and Reconstruction (Institution of Municipal and County Engineers), 311
Post-War Reconstruction : Nature Preservation in (Society for the Promotion of Nature Reserves conference on), 707
Potato : Genetics of the (C. H. Cadman), 26
  (Cooked), Loss of Thiamin from (Dr. Jane Meiklejohn), 81
Potato Blight (*Phytophthora infestans*) by Spraying with Suspensions of Metallic Copper : Control of (E. C. Large), 80
Potato Tips as Seed, 77
Potato Virus Diseases in Victoria (J. G. Bald and A. T. Pugsley), 501
Potato Witches' Broom Transmission by Dodder and Cure by Heat (L. O. Kunkel), 477
Potatoes and War Economy (Dr. Maurice Copisarow), 421 ; (Dr. Nicholas Polunin), 587
Potatoes (Mashed) : Ascorbic Acid in (G. N. Jenkins), 473
Powder Dry : And Keep Your (Margaret Mead), *review* by Prof. H. J. Fleure, 405
Power Stations (Secondary) : The Effect of the National Grid on the Operation and Maintenance of (R. A. W. Connor), 565
Power Supply Lines : Standardization of Overhead, 445
Practice (Theory and) of Heat Engines (D. A. Wrangham), *review* by Dr. O. A. Saunders, 571
Prawn, *Leander serratus* : The Giant Myelinated Fibres in the (William Holmes), 282
Prawn Fisheries of India (Dr. B. Chopra), 556
Precautions against Chemical Warfare, *review*, 404
Precipitin Reaction : A Quantitative Theory of the (Prof. Torsten Teorell), 696
Pregnancy : Food and, 321
  Nutrition in (Nutrition Society conference on), 321
Prehistoric Archæology of North-West Africa (Frederick R. Wulsin), *review* by M. C. Burkitt, 36
Prehistory of North America, 282
Preparation of Deuterium Chloride (H. C. Brown and C. Groot), 57

Preparation of Teachers in Health Education, 593
Presentation (Museum) of Geology, *review*, 6
Preservative ('Greensalt') for Telephone Poles (C. M. Hill), 302
Preservation of Timber in Rhodesia (R. H. Finlay), 423
Press : Science and the, 595
Pressor Substances in Urine and Plasma from Normal and Hypertensive Subjects (Prof. U. S. v. Euler and T. Sjöstrand), 168
Pressure and Volume of a Gas : Accuracy of Boyle's Original Observations on the (Dr. R. C. Geary), 476
Primitive People: Psychology of a, *review* by Dr. H. G. Baynes, 711
Primitive Tribe : Wooden Implements of a, 56
Prince Edward Island (to the west of) : Earthquake on November 10, 106
Princeps Concordiae, Pico della Mirandola and the Scholastic Tradition (Avery Dulles), *review* by the Rev. J. C. Hardwick, 710
Principles of Stellar Dynamics (S. Chandrasekhar), *review* by Sir Arthur Eddington, 91
Printing (Colour) : The Use of Fluorescent Pigments in (F. W. Coppin), 73
Prism Manufacture (Lens and) : The Interferometer in (F. Twyman), 43
Prism and Lens Making (F. Twyman), *review* by H. W. Lee, 458
Problem of Unemployment (Unilever Ltd. and Lever Brothers), 344
Problems : of American Unity (T. Raymont), 677
  of Communal Feeding, 134
  of Geomorphology, *review* by Prof. A. E. Trueman, 598
  (Some) in Transmission-Line Design (A. Burke), 106
Production of Ion Clusters by X-Rays (U. Fano), 698
Production of Leaf Palisade Tissue : Factors in the (R. W. Watson), 113
Production of Magnesium (Prof. F. C. Thompson), 692
Production and Advisory Committees, Joint, 156
Production Genetics in Sweden (Dr. C. D. Darlington), 183
Progress : A Century of—Men, Manners, Inventions (Dr. E. F. Armstrong), 257
Progress of Applied Chemistry : Reports of the, Vol. 26, 1941, *review*, 95
Progress of Army Medicine, *review* by Major J. Marshall, 627
Progress of Chemistry for 1941 : Annual Reports on the, Vol. 38, *review*, 95
Progress (Scientific) since 1840, 257
Projector for Navigational Stars : New, 192
Proliferation-promoting Substances from Injured Cells (J. R. Loofbourow), 141
Properties (The Extreme) of Matter (Sir Charles Darwin), 237
Properties (Frictional) of Metallic Films (Dr. Robert Schnurmann), 420 ; (Dr. T. P. Hughes), 533
Prosthecium, (Melanconis, Pseudovalsa,) and Titania : A Revision of (Lewis E. Wehmeyer), *review* by E. W. Mason, 208
Protection of Electric Power Systems, *review* by Dr. L. E. C. Hughes, 683
Protection of Structures against Lightning (J. F. Shipley), 638
Protection (Automatic) of A.C. Circuits (G. W. Stubbings), third edition, revised, *review* by Dr. L. E. C. Hughes, 683
Protozoa : Flocculation of Bacteria by (Garrett Hardin), 642
  Vitamin C in the (G. Roskin and O. Nastiukova), 337
Pseudo-Science : Science or (C. W. Hansel), 618
Pseudovalsa, (Melanconis,) Prosthecium and Titania : A Revision of (Lewis E. Wehmeyer), *review* by E. W. Mason, 208
Psychology of a Dynamist : "Vis et Præterea Nihil"—The, *review* by Dr. J. Leycester King, 150
Psychology of a Primitive People, *review* by Dr. H. G. Baynes, 711
Psychology in the Sciences : Place of (Prof. T. H. Pear), 638
Psychology in the United States : Post-War Planning of, 677
Pub and the People, The: a Worktown Study (Mass Observation), *review* by Lieut. T. H. Hawkins, 235
Public Appreciation of Science (H. Brewer), 534
Public (General) : Presentation of Science to a (Dr. Arnold Raestad), 547
Public Health in Chile, 135 ; (Dr. Juan Antonio Rios), 668
Public Health: Livestock Management and (Backs to the Land Club discussion on), 417
Public Library in Reconstruction, 317
Public Library System of Great Britain (L. R. McColvin), 317
Pump Control System : Floatless, 135
Pumping (Mine) : Application of Electricity in (G. B. Alvey and N. Tetlow), 79
Purine Nucleosides : Configuration of (Prof. J. M. Gulland, G. R. Barker and D. O. Jordan), 109
Purple : Visual (Prof. Ragnar Granit), 631
Pyridine : A New Synthesis of (W. W. Crouch and H. L. Lochte), 702

QUALITATIVE Chemical Analysis of Inorganic Substances : A Course of Instruction in the (Prof. Arthur A. Noyes), tenth edition, revised and rewritten by Prof. Ernest H. Swift, *review*, 657
Quality of Glassware : Cords, Surface Condition and, 106
Quantitative Theory of the Precipitin Reaction (Prof. Torsten Teorell), 696
Quantum Statistics, Chemical Equilibria and Reaction Kinetics, *review* by Dr. C. H. Bamford, 320
Quenching of Fluorescence by Nitric Oxide (Dr. H. Weil-Malherbe and Dr. Joseph Weiss), 449
Question and Answer : The Logic of (Prof. A. D. Ritchie), 498

RABBIT : Effect of Hexoestrol and of α-Methyl Stilbene on the Insulin Content of the Pancreas of the (Dr. Mervyn Griffiths), 82
  Phagocytosis in the Appendix of the (Frank Baker and John Enticknap), 532
Raça el do Esperito (Prof. A. A. Mendes Corrêa), 300
Race Theories (Prof. F. Wood Jones), 220
Radiation (Ultra-Violet) : Magnetization of Matter by (S. L. Martin and A. K. Connor), 167
Radio Exploration of the Ionosphere (Sir Edward Appleton), 497
Radio Fade-Out in Sweden (Dr. O. E. H. Rydbeck), 700
Radio Method : The Determination of the Location and Frequency of Thunderstorms by a (J. S. Forrest), 285
Radio Receiver Design, Part I : Radio Frequency Amplification and Detection (Dr. K. R. Sturley), *review*, 657
Radio Telephone : Coastal (H. M. Pruden). 732
Radio Wave Propagation : Ultra-Short (Dr. R. L. Smith-Rose and Miss A. C. Stickland), 31
Radio Waves : A Simple Method of Demonstrating the Circular Polarization of Ionospherically Reflected (Sir Edward V. Appleton), 250
γ-Radiography (C. Croxson), 424
Radiography (Indirect) as Applied to Medical Work (Miss K. C. Clark), 718
Radiography (Industrial) : Some Miscellaneous Applications of (Dr. L. Mullins), 719
Radiologic Physics (Charles Weyl, S. Reid Warren, Jr., and Dallett B. O'Neill), *review* by Prof. F. L. Hopwood, 348
Rare Earths, 645
Rat Infestation on Vessels (Dr. Robert Olesen and G. C. Sherrard), 499
Rationing : War-time Consumption and (League of Nations Publication 1942, II, A. 2), 371
Rats (Rachitic) : Action of Fluorine on the Teeth of (Prof. J. T. Irving), 363
Raw Materials : Control of, 452
Rays (Cosmic) : An Exceptional Increase of (Prof. A. Duperier), 308
  Origin of (Dr. R. A. Millikan, Dr. H. V. Neher and Dr. W. H. Pickering), 663
Reaction Kinetics (Quantum Statistics, Chemical Equilibria, and), *review* by Dr. C. H. Bamford, 320
Reactions : Co-Enzymatic (Prof. J. K. Parnas), 577
Reactivity (Chemical) : Resonance and (Prof. M. Polanyi), 96
Reclamation of Bracken-land (Dr. Maurice Copisarow), 139
Reconstruction : Economic, 343
  Hydro-Electric Developments and, 177
  Post-War Planning and (Institution of Municipal and County Engineers), 311
  The Public Library in, 317
  Universities and, 147
Reconstruction in Birmingham and the West Midlands (Councillor Paul Cadbury), 667
Reconstruction in Canada : Science and (Prof. J. K. Robertson), 444
Reconstruction and a Council of Europe (Winston Churchill), 359
Reconstruction Problems in School and Home (Report by the Electrical Association for Women), 417
Reconstruction and Social Security, 33
Recorder : A Spread-Scale (O. D. Engstrom), 257
Recording Technique (Amplifying and) in Electro-Biology (G. Parr and W. Grey Walter), 330
Re-educating the Germans (Prof. T. H. Pear), 684
Refraction : Conical (Sidney Melmore), 620
Refractive Index of Coals (C. G. Cannon and Dr. W. H. George), 53
Refrigeration : Pioneers of (Eng.-Capt. Edgar C. Smith), 412
Regional Boundaries in Great Britain (Association for Planning and Regional Reconstruction), 584
Rehabilitation of Fundamental Research (Prof. P. M. S. Blackett), 157
Relation of Hypopituitarism and Starvation (Dr. Erwin P. Vollmer), 698
Relaxation Methods, a Mathematics for Engineering Sciences (Prof. R. V. Southwell), 723
Religious Education and a New Solution : The Riddle of (Adam Gowans Whyte), *review*, 95
Renal Excretion of Pituitary (Posterior Lobe) Extracts (Dr. H. Heller), 502
Rennin : Pure Crystalline (Dr. N. J. Berridge), 473
Reorganization : World, *review* by Lord Horder, 374
Reproductive Capacity of Plants (Prof. E. J. Salisbury), *review*, 319
Research : Antarctic, 647
  on Cancer, 445
  Co-operation in, 300
  in the Control of Injurious Insects, Place of (Prof. J. W. Munro), 157
  in the Netherlands Indies (Dr. P. Honig), 242
  in the United States (Sir Ernest Simon), 693
Research (Agricultural) in Great Britain (Agricultural Research Council report on), 396
Research (Animal Cell Growth): Charles L. Mayer Awards for, 19
Research (Avalanche) in Switzerland, 528
Research (Biogeochemical) in the U.S.S.R. (A. P. Vinogradov), 659
Research (Cancer) : Mythology of (Prof. E. L. Kennaway), 302
Research (Coal Utilization) and the National Economy, 709
Research (Colonial) in the British Empire (Dr. Lucy Mair), 87
Research (Fundamental) : The Rehabilitation of (Prof. P. M. S. Blackett), 157
Research (Industrial) in Great Britain, a Policy for the Future (Dr. P. Dunsheath), 259
Research (Metallographical) in Sweden, 529
Research (Scientific and Industrial) in India, 329
Research (Subatomic) : Valve Technique in, *review* by Dr. L. Jánossy, 377
Research (Sylvicultural) in Bengal (D. A. G. Davidson), 135
Research (Synthetic Textile) in Germany, 115
Research and Development : Scientific, 203
Research and Industrial Efficiency, 259
Research Worker : The Making of a (O. T. Faulkner), 332
Resident Habit of many British Birds : Autumn Sexual Behaviour and the (Dr. W. S. Bullough), 531
Resistance (Electrical) of Wood (W. W. Barkas, R. F. S. Hearmon and G. H. Pratt), 83
Resonance and Chemical Reactivity (Prof. M. Polanyi), 96
Retinal Receptors : Spectral Sensitivity of the (Dr. W. D. Wright), 726
Reynolds (Osborne) Medal for 1942 of the Institution of Chemical Engineers presented to Mr. L. O. Newton, 418
Rheological Problems in the Rubber Industry (Dr. J. R. Scott), 563
Rheological Properties : Classification of (Dr. R. Bartlett), 198
Rheological Series (Robert H. S. Robertson and H. W. J. Hathaway), 728
Rheology of Rubber (Manchester section of the Institution of the Rubber Industry and the British Rheologists' Club conference on), 563
Rhodesia : Preservation of Timber in (R. H. Finlay), 423
Rhodesia (Southern) : Rock Paintings of (L. Cripps), 472
Rhoeo discolor and Tradescantia : Cytology of (P. N. Bhaduri), 56
Rhythms (Seasonal) in Man, *review* by Prof. W. E. LeGros Clark, 66
Riddle of Religious Education and a New Solution (Adam Gowans Whyte), *review*, 95
River Flow Records of the Ness Basin, 1929–1942 (Capt. W. N. McClean), 528
Rock Paintings of Southern Rhodesia (L. Cripps), 472

Rocks (Intrusive), Ontario : Age Determinations of (H. C. Horwood and N. B. Keevil), 701
Role of Blue-Green Algæ in Nitre Formation in Deserts (S. V. Odintzova), 701
Root Nodules : Anatomy of Leguminous (Miss Helen L. Frazer), 141
Rose Hips : Vitamins in (Frank Wokes, E. H. Johnson, Joan G. Organ and F. C. Jacoby), 279
Royal Aircraft Establishment, Farnborough (E. Mardles), 562
Rubber : Rheology of (Manchester section of the Institution of the Rubber Industry and the British Rheologists' Club conference on), 563
Rubber in Elongation, Compression and Shear : The Behaviour of (Dr. L. R. G. Treloar), 563
Rubber : Synthetic (Dr. Harry Barron), 175 ; (Dr. W. J. S. Naunton), 175
Rubber Industry : Rheological Problems in the (Dr. J. R. Scott), 563
Rubber-like State on the Plastic-elastic Scale : The Position of the (R. C. Seymour and J. M. Buist), 563
Rumex Lunaria L., a Gynodioecious Tetraploid Species (Dr. Askell Löve), 559
Rumford's Contributions to Nutrition (A. F. Dufton), 199
Russia : Development of Biological Science in (Ch. S. Koshtoyants), 408
Russian Physiologists : Greetings from, 79
Russian Scientific and Technical Periodicals in Great Britain, 77

SALMON : The Spawning Habits of (G. M. King), 330
  of the River Erne, 282
Salvage or Storage (Association of Special Libraries and Information Bureaux), 512
San Jon District, Eastern New Mexico : Archæological and Geological Investigations in (F. H. Roberts), 282
Sanitary Congress : Panamerican, 303
Saponin of Fenugreek Seeds (Dr. Gabra Soliman and Miss Zahira Mustafa, 195
Saturation Test (Vitamin C) of Harris and Abbasy (Dr. W. R. G. Atkins), 21
Saturation Test (Vitamin C) : Standardization Measurements at Graded Levels of Intake (Dr. Leslie J. Harris), 21
Scabies (Dr. Kenneth Mellanby), *review*, 377
Scale Insects of North America : Atlas of the (G. F. Ferris), Fourth Series, *review*, 657
Scales and Data : Results of the Examination of a Small Collection of (Arthur E. J. Went), 282
Scholasticism : Newtonianism and, 59
School (Continuation) : Future of the, 567
School Children in South Africa : Physical Fitness of (Prof. D. Burns), 704
School Science Teaching after the War (E. T. Harris), 78
School and Home : Reconstruction Problems in (Report by the Electrical Association for Women), 417
Schools : War-time Nursery (Mrs. F. A. Ogden), 100
Science : Freedom in (Dr. H. Lowery), 295
  Historical Method in Teaching (Manchester Literary and Philosophical Society discussion on), 417
  History of, *review* by Dr. W. H. S. Jones, 404
  Public Appreciation of (H. Brewer), 534
  Studies in the History of (E. A. Speiser, Otto E. Neugebauer, Hermann Ranke, Henry E. Sigerist, Richard H. Shryock, Evarts A. Graham, Edgar A. Singer, Hermann Weyl), *review* by Dr. W. H. S. Jones, 404
Science in the Service of Art, 133
Science, Christianity and Truth (Rev. Canon A. E. Baker), *review* by the Rev. J. C. Hardwick, 710
Science and the Citizen (British Association, Division for the Social and International Relations of Science, conference on), 191, 382, 595, 607
Science and Ethics (Dr. C. H. Waddington), *review*, 657
Science to a General Public : Presentation of (Dr. Arnold Raestad), 547
Science as a Humanity (Prof. W. G. de Burgh), 607
Science and the Press, 595
Science or Pseudo-Science (C. W. Hansel), 618
Science and the War Effort in the United States, 389
Science, Common Sense and Decency (Dr. Irving Langmuir), 266 ; (Adam Gowans Whyte), 450 ; (A. J. Bateman), 450 ; (William P. D. Wightman), 589 ; (E. Denne), 589
Science and the Educational System, 156
Science and Government (Sir John Anderson), 219 ; *erratum*, 249
Science in Great Britain ; Government and (Sir Stafford Cripps), 152, 154, 203
Science in India (D. N. Wadia), 548
Science and Industrial Management, 156
Science and Industry : Photography in (Herbert E. Zerkowsky), 501
Science and Parliament, 156
Science and Reconstruction in Canada (Prof. J. K. Robertson), 444
Science and the Soldier, 155
Science and the United Nations, 58
Science in War and Peace: Planning of (Association of Scientific Workers conference on), 20, 152, 153, 203
Science (Biological) in Russia: Development of (Ch. S. Koshtoyants), 408
Science (Organization of) : in Great Britain, 206
  in the U.S.A., 207
  in the U.S.S.R., 207
Science (War-time) in the U.S.S.R. (Dr. David Shoenberg), 154
Science, Inventions and Industrial Technology : Stalin Prizes for, 425
Science Students and Industrial Experience, 164
Science Teaching (School) after the War (E. T. Harris), 78
Sciences : Place of Psychology in the (Prof. T. H. Pear), 638
Scientific Approach to History, *review* by F. S. Marvin, 486
Scientific Centenaries in 1943 (Eng.-Capt. Edgar C. Smith), 15
Scientific Conception of the Universe : Chance, Freewill, and Necessity in the (Prof. E. T. Whittaker), 612
Scientific Discoveries by Accident (T. Ll. Humberstone), 215
Scientific Front : News and Views from the (Sir Richard Gregory), 517
Scientific Instrument : Photography as a, 718
Scientific Planning : The Basis of (Prof. H. Levy), 157
Scientific Progress since 1840, 257
Scientific Research and Development, 203
Scientific Resources for Total War : The Fuller Utilization of (Dr. T. Rosebury), 389
Scientific Study : Education as a, *review* by T. Raymont, 460
Scientific Workers : Trade Unionism and, 446
Scientific and Industrial Photographers, 501
Scientific and Industrial Research in India, 329
Scientific and Technical Board : A Central, 155
Scientific and Technical Periodicals : Conservation of, 512
Scientists of the United Nations and the War Effort (Association of Scientific Workers conference on), 58
Scientists after the War : The Position of (Sir Lawrence Bragg), 157
Scientists (American) for the War : The Organization of (Pilgrim Trust Lecture of the Royal Society by Dr. Karl T. Compton), 362, 601
Scotland : Hydro-Electric Development in, 177, 187, 528
Scots Pine (Larch and) Poles suitable for Transmission Lines, 194
Scott (James) Prize address for 1943 of the Royal Society of Edinburgh on The Fundamental Concepts of Natural Philosophy (Prof. E. A. Milne), 530
Scottish South West Isles : Archæological Finds in the (J. Harrison Maxwell), 282
Sea Waves : Theory of (P. J. H. Unna), 479
Seamen's Welfare in Port : Welfare Outside the Factory and (Report issued by the Ministry of Labour and National Service), 116
Search for New Insecticides (Dr. J. R. Busvine), 690
Seasonal Influence on Growth, Function and Inheritance (A. B. Fitt), *review* by Prof. W. E. LeGros Clark, 66
Seasonal Rhythms in Man, *review* by Prof. W. E. LeGros Clark, 66
Seaweeds (South African) : Agar from (Wm. Edwyn Isaac, H. Finlayson and M. Gavine Simon), 532
Security (Social) : Reconstruction and, 33
Seed (Cereal) : Disinfection of, 194
Seed (Forest Tree) of the North Temperate Regions, with Special Reference, to North America (Henry Ives Baldwin), *review* by T. Thomson, 93
Seed Dispersal by Human Activity (A. J. Healy), 140
Seed Supply in War-time (L. E. Cook), 114
Seedling (Grass) : Physiology of the (R. L. Weintraub and E. D. McAlister), 477
Seedling (Maize) : Physiology of the (J. H. Kempton), 477
Seeds (Fenugreek) : The Saponin of (Dr. Gabra Soliman and Miss Zahira Mustafa), 195
Seeing Ever-Smaller Worlds (Sir Lawrence Bragg), 545
Seismograph (Benioff Vertical-Component) to be installed at the National Astrophysical Observatory, Tonantzintla, 530
Seismological Tables (Dr. H. Jeffreys and Dr. K. E. Bullen), 472
Self (My), My Thinking, My Thoughts (K. W. Monsarrat), *review* by Dr. J. Leycester King, 150
Senonian Echinocorys (English) : An Application of the Principles of Allometry to the Study of (Dr. John F. Hayward), 617
Sensitivity (Spectral) of the Retinal Receptors (Dr. W. D. Wright), 726
Sensitometry since Hurter and Driffield (Dr. S. O. Rawling), 210
Separation of Ytterbium from the neighbouring Rare-Earth Elements (J. K. Marsh), 645
Separation (Automatic) of Wet from Dry Grain for Storage (T. A. Oxley and Dr. F. Y. Henderson), 223
Sequoias : Californian (Looby and Doyle), 142
Sevenoaks or Western District of Kent : A Handlist of the Birds of the (James M. Harrison), *review*, 151
Sewage Purification : Loss of Phosphorus during (Dr. S. H. Jenkins and W. T. Lockett), 306
Sewage Purification Plant : Town-Planning and the Small (Dr. Ll. Lloyd), 475
Sewage Purification Plant at Dadar, Bombay : The Operation of a (N. V. Modak), 646
Sewage Treatment in a Tropical City (Dr. Ll. Lloyd), 646
Sex-determination in the Wood-louse (H. W. Howard), 701
Sex Difference in Blood-Group Frequencies (Prof. R. A. Fisher and Dr. J. A. Fraser Roberts), 640
Sex Education and Guidance (Dr. R. Sutherland), 356
Sex Ratio in Cattle (J. W. Gowen), 56
Sexual Behaviour (Autumn) and the Resident Habit of many British Birds (Dr. W. S. Bullough), 531
Sexuality in a Planarian (Dr. Libbie H. Hyman), 140
Shape of Pebbles (Lord Rayleigh), 338
Sheep 'Pining' in Britain (W. Lyle Stewart), 29
Shigella dysenteriæ (Shiga) in a Synthetic Medium : Production of Potent Toxins by (Dr. L. Olitzki and P. K. Koch), 334
Short-Wave Broadcasting, Ten Years' Technical Progress (Sir Noel Ashbridge), 17
Sierra Tejada : Earthquake on January 9, 584
Silage-making (W. McLean), 114
Silicified Plants, Indian : 1, *Azolla intertrappea* Sahni and H. S. Rao (B. Sahni), 338
Silkmoth Rearer's Handbook, 499
Silver (Tervalent) : A New Type of Complex Silver Compounds with (Prof. P. Rây), 643
Silver Alloys : Hardness of (J. H. Frye, jun., and W. Hume-Rothery), 57
Silver (Complex) Compounds with Tervalent Silver : A New Type of (Prof. P. Rây), 643
Sky : Coloured Arc in the (Miss F. E. Penrose), 300
  (The Night) : in February, 136 ; in March, 249 ; in April, 362 ; in May, 501 ; in June, 613 ; in July, 724
  The Tropical (Compiled by H. E. Watson), *review*, 378
Slugs : Effect of Air Currents, Light, Humidity and Temperature on (Mrs. Barbara H. Dainton), 25
Social Biology : Vacation School on (British Social Hygiene Council), 389
Social Philosophy : The 'New Deal' as a (Prof. D. Mitrany), 134
Social Security : Reconstruction and, 33
Social System : Personality, Disease and the (P. J. Kloppers), 705
Social Welfare in the Colonies, 275
Social and Industrial Environment and Disease (Prof. M. Greenwood), 275
Society of Fellows Foundation at Harvard, 472
Society of Glass Technology : *Journal of the*, Vol. 26, No. 116, 106
Soft-Iron Electrical Instruments : Torque of ((Dr. C. V. Drysdale), 423
Soil Characteristics : Human Activities and (Dr. F. E. Kenchington), 83
Soil Conditions affecting Production of Perithecia in Banana Leaf Spot Disease (R. Leach), 199
Soil Fertility : Leaf Analysis as a Guide to (Prof. H. Lundegårdh), 310
Soil Management : Soils and (Prof. A. F. Gustafson), *review*, 95

Soil Nitrogen : Improvement of the Nitrogen Status of Soils and the Origin of (Prof. N. R. Dhar), 590
Soils and Grasses : Distribution of Trace Elements in (Dr. R. L. Mitchell), 28
Soils and Soil Management (Prof. A. F. Gustafson), *review*, 95
Soils and the Origin of Soil Nitrogen : Improvement of the Nitrogen Status of (Prof. N. R. Dhar), 590
Solanum : Incompatibility in (—. Pushkarnath), 338
Solar Corona : Temperature of the (Dr. V. Vand), 728
Soldier : Science and the, 155
Solution (Non-Aqueous) : Mode of Chemical Action of X-Rays on a (Dr. E. Broda), 448 ; *erratum*, 530
Solway Tides, 51
Somerset ('Teart' of), a Molybdenosis of Farm Animals (W. S. Ferguson), 30
Source Book of Mathematical Applications (National Council of Teachers of Mathematics, Seventeenth Yearbook), *review* by Dr. W. G. Bickley, 626
South African Seaweeds : Agar from (Wm. Edwyn Isaac, M. H. Finlayson and M. Gavine Simon), 532
South Seas in the Modern World (Prof. Felix M. Keesing), *review* by Dr. Lucy Mair, 625
Soviet Forms in Communal Feeding (F. le Gros Clark), 134
Soviet Medical and Scientific Men, 444
Soviet Planning in War-time (P E P Broadsheet), 50
Soviet Union : Advances of Chemical Kinetics in the (Nikolai Semenov), 185
  The Peoples of the (Dr. Aleš Hrdlička), 20
Space: Absolute Time and (Dr. G. Burniston Brown), 85
Spain : Earthquakes registered during September, 51 ; during October, 194 ; during January, 584 ; during March, 695
Spanish Astronomical Data, *review*, 405
Spawning Habits of Salmon (G. M. King), 330
Species : Systematics and the Origin of (Ernst Mayr), *review* by Dr. Julian Huxley, 347
Specific Heats of Hydrocarbons (B. P. Dailey and W. A. Felsing), 702 ; (J. F. Lemons and W. A. Felsing), 702
Spectra (Flame) in the Photographic Infra-Red (Dr. A. G. Gaydon), 645
Spectral Sensitivity of the Retinal Receptors (Dr. W. D. Wright), 726
Spectrophotometric Estimation of Vitamin A in Fish Liver Oils (J. I. M. Jones and R. T. M. Haines), 57
Spectrum (A New Band) Associated with Nitrogen (Dr. A. G. Gaydon) 167
Spectrum (X-Ray) of Phosphorus Pentachloride (D. Clark and H. M. Powell), 27 ; (A. F. Wells), 27
Speech and Voice, their Evolution, Pathology and Therapy (Dr. Leopold Stein), *review* by Dr. L. E. C. Hughes, 292
Sterilization of Sulphanilamide Powder, 389
Spermatozoon (Cavia) : Middle-Piece Beads in the (Prof. J. Brontë Gatenby and L. Collery), 253
Spore Germination Tests : Behaviour of Thiuram Sulphides, etc., in (H. B. S. Montgomery and Dr. H. Shaw), 333
Spraying with Suspensions of Metallic Copper : Control of Potato Blight (*Phytophthora infestans*) by (E. C. Large), 80
Spread-Scale Recorder (O. D. Engstrom), 257
Srinagar : Earthquakes on September 21 and December 25, 136
Sta. Cruz Quiche, Guatemala : Earthquake on January 24, 530
Stability of Ascorbic Acid in Dehydrated Vegetables (Dr. W. R. Aykroyd), 22
Staffordshire Ecology, 302
Staining Schedules (Biology) for First Year Students (R. R. Fowell), *review* by Prof. R. C. McLean, 572
Stalin Prizes for Science, Inventions and Industrial Technology, 425
Standardization in Great Britain of Single-Circuit Overhead Lines up to 33 kV. (H. Willott Taylor and K. L. May), 445
Star Magnitudes and Image Diameters in Photographic Photometry (D. L. Edwards), 31
Star Projector : A Bausch and Lomb Artificial (James R. Benford), 192
Stars (Convective) : Colour Temperature of (W. S. Tai and A. D. Thackeray), 478
Stars (Navigational) : New Projector for, 192
Starvation : Relation of Hypopituitarism and (Dr. Erwin P. Vollmer), 698
State of Health in Europe, 117
Statistical Analysis in Biology (Dr. K. Mather), *review* by Prof. J. B. S. Haldane, 654
Statistics : Biological, *review*, 319
Steam (High-Velocity) : Electrical Detector of Condensation in (A. M. Binnie and J. R. Green), 283
Steam-boat Pioneer : An American, 76
Steel (Mild) in Compression : X-Ray Elasticity Measurements for (S. L. Smith and W. A. Wood), 113
Steels for the User (R. T. Rolfe), second edition, *review*, 600
Stellar Dynamics : Principles of (S. Chandrasekhar), *review* by Sir Arthur Eddington, 91
Stereotypy of Instinctive Behaviour (Dr. E. S. Russell), 612
Steroids : An Attempt at a Natural Classification of the (Prof. Hans Selye) 662
Stibamine (Urea) : Antimony Content and Toxicity of (R. C. Guha, N. K. Dutta and Dr. B. Mukerji), 108
Stilbamidine Solution on Exposure to Light : Increase in Toxicity of (Dr. H. J. Barber, R. Slack and E. Wien), 107
Stilbene (α-Methyl) on the Insulin Content of the Pancreas of the Rabbit : Effect of Hexoestrol and of (Dr. Mervyn Griffiths), 82
Stilboestrol and its Esters : Isomers of (E. Walton and G. Brownlee), 305 ; (Prof. E. C. Dodds and Sir Robert Robinson), 305
Stimulative Effect (Apparent) on Mould Growth of a Mercurial Preparation (Dr. Madge E. Robertson), 365
Stimulators (Growth) in Urinary Extracts (J. H. Thompson, Dr. P. F. Holt and Dr. R. Forbes Jones), 23
Stoat (*Mustela mustela*) : Delayed Implantation in the (Dr. Ruth Deanesly), 365
Stone Age : The Irish (Dr. Hallam L. Movius, Jr.), *review* by C. F. C. Hawkes, 376
Stone Men of Malekula, Vao (John Layard), *review* by Dr. H. G. Baynes, 711
Stone Tools (Simple) ; An Unrecorded Method of Manufacturing Wooden Implements by (C. B. Mountford), 56
Stones (Bored) of South Africa (A. J. H. Goodwin), 26
Storage : Salvage or (Association of Special Libraries and Information Bureaux), 512
Straw (Buried Wheat) : Colonization of, by the Fungus *Fusarium culmorum* (Alan G. Walker), 283
Streptococci : Group *N* (Dr. A. T. R. Mattick and P. M. F. Shattock), 278
Stress Patterns (Photo-elastic) : The Photography of (H. McGregor Ross), 720
Structural Changes in Cold-worked Metals : New X-Ray Evidence on the Nature of the (Dr. W. A. Wood), 585
Structure of Keratin Fibres (Dr. J. L. Stoves), 304
Structure of the Universe (Sir James Jeans), 490
Structure (Crystal) of Graphite (Dr. H. Lipson and A. R. Stokes), 27
Structure (Crystal) of Phosphorus Pentachloride, 27
Structure (Molecular) of Ozone (W. Shand and R. A. Spurr), 645 ; (C. P. Smyth and G. L. Lewis), 645
Studia Moritura (Alan S. C. Ross), 699
Subantarctic and Antarctic Waters : Communities of Marine Algæ in (C. Skottsberg), 26
Subatomic Research : Valve Technique in, *review* by Dr. L. Jánossy, 377
Sub-standard Kine-photo-micrography (C. D. Reyersbach), 720
Sudan (Anglo-Egyptian) : A Middle Pleistocene Discovery in the (G. Andrew and A. J. Arkell), 226 ; (E. J. Wayland), 334
Sulphonamide Inhibitors : Counteracting (Dr. W. K. S. Wallersteiner), 586
Sulphanilamide Powder : Sterilization of, 389
Sulphonamides : Use and Abuse of (Buckston Browne prize essay for 1943–44 of the Harveian Society of London), 221
Sun in A.D. 45 : The Eclipse of the (C. J. Westland), 111
Sunspot Cycle : Ionospheric Variations during the, 497
Supernormal Factors in Human Personality (Dr. B. L. Atreya), 556
Surface Condition (Cords,) and Quality of Glassware, 106
'Swayback' (Enzootic Ataxia or) of Lambs in England in relation to Copper Feeding of Ewes during Pregnancy (Prof. T. Dalling), 29
Sweden : Metallographical Research in, 529
  Production Genetics in (Dr. C. D. Darlington), 183
  Radio Fade-Out in (Dr. O. E. H. Rydbeck), 700
Sweden Speaks (edited by Gustaf Witting, translated by Edith M. Nielsen), *review* by J. G. Crowther, 656
Swedish Forest Products, 165
Swedish View of Britain, *review* by J. G. Crowther, 656
Switchgear Practice (Arthur Arnold), *review*, 572
Switzerland : Avalanche Research in, 528
Sylvicultural Research in Bengal (D. A. G. Davidson), 135
Symmetry with Temperature : A Change of (G. D. Preston and J. Trotter), 166
Synthesis of Pyridine : A New (W. W. Crouch and H. L. Lochte), 702
Synthesis (Laboratory) of Diamond (F. A. Bannister and Dr. K. Lonsdale), 334 ; (Lord Rayleigh), 394
Synthesis (New) of Glycolesters (M. S. Kulpinski and Prof. F. F. Nord), 363
Synthesis (Urea) in Mammalian Liver (Dr. H. A. Krebs), 23 ; (Dr. S. J. Bach and S. Williamson), 23
Synthetic Differential Growth Inhibitor (P. B. Medawar, Lady Robinson and Sir R. Robinson), 195
Synthetic (Natural and) High Polymers (Prof. Kurt H. Meyer, translated by Dr. L. E. R. Picken), *review* by Prof. H. W. Melville, 682
Synthetc Rubber (Dr. Harry Barron), 175 ; (Dr. W. J. S. Naunton), 175
Synthetic Textile Research in Germany, 115
Syria (North) as a Cultural Link in the Ancient World (Sir Leonard Woolley), 144
Systematic and Taxonomic Studies on the Flora of India and Burma (Dr. Kalipada Biswas), 580
Systematics and the Origin of Species (Ernst Mayr), *review* by Dr. Julian Huxley, 347
Systems with Boron Trifluoride (H. S. Booth and D. R. Martin), 113

TAKE-ALL' Disease of Wheat and Associated Fungi, 283
Tariff : Towards the 'Correct' Dometic Multi-Part (P. Schiller), 220
Tariffs : General Factors Affecting the Unification of Electricity Supply (C. T. Melling), 301
Taxonomic Studies (Systematic and) on the Flora of India and Burma (Dr. Kalipada Biswas), 580
Tea : Oxidation of Ascorbic Acid in (G. A. Snow and S. S. Zilva), 112
Teachers in Health Education : Preparation of, 593
'Teart' of Somerset, a Molybdenosis of Farm Animals (W. S. Ferguson), 30
Technical Board : A Central Scientific and, 155
Technical Education to the Building Industry : Relation of, 427
Technical (Scientific and) Periodicals : Conservation of, 512
Technology : Modern Advances in, *review* by Dr. L. E. C. Hughes, 208
Technology (Electrical), *review* by Dr. L. E. C. Hughes, 713
Technology (Electrical) for Telecommunications (W. H. Date), *review* by Dr. L. E. C. Hughes, 378
Technology (Industrial) : Stalin Prizes for Science, Inventions and, 425
Teeth of Rachitic Rats : Action of Fluorine on the (Prof. J. T. Irving), 363
Tehuantepec (Isthmus of) in Central America (to the east of Chimalapa in the) : Earthquake on November 12, 106
Telecommunications : Electrical Technology for (W. H. Date), *review* by Dr. L. E. C. Hughes, 378
Telephone : Coastal Radio (H. M. Pruden), 732
Telephone Cables : Measurement of Lightning in relation to (J. J. Mahoney, jun.), 537
Telephone Poles : 'Greensalt' Preservative for (C. M. Hill), 302
Telephone Set (A New) for Partially Deaf Persons (A. Herckmans), 79
Telephone Sets : Simplified Subscribers' (E. S. McLarn), 556
Telephony (Wire) : Evolution of (George H. Gray), 227
Telescope : First Steps in Astronomy without a (P. F. Burns), *review*, 151
Temper of British Ideals (Prof. John Laird), *review* by R. Brightman, 543
Temperate Zone : National Vigour and the, *review* by Prof. H. J. Fleure, 431
Temperature : A Change of Symmetry with (G. D. Preston and J. Trotter), 166
Temperature of the Solar Corona (Dr. V. Vand), 728
Temperature (Effect of Air Currents, Light, Humidity and) on Slugs (Mrs. Barbara H. Dainton), 25

Temperature (Colour) of Convective Stars (W. S. Tai and A. D. Thackeray), 478
Temperature (Medium) : Thermal Insulation at (A. C. Pallot), 593
Tennessee Valley Authority, an Experiment in Regionalism (K. S. Lomax), 592
Terminology in the Geological Sciences (Dr. R. H. Rastall), 294, 447; (Prof. A. E. Trueman), 447; (Dr. Alan Wood), 447; (F. Wolverson Cope), 503
Ternary Azeotropic Mixtures : Determination of the Water Content of Wood and other Substances by means of (Dr. W. R. G. Atkins), 449
Terrestrial Matter and the Geochemical Uranium/Lead Ratio : The 'Age' of (F. F. Koczy), 24
Tervalent Silver : A New Type of Complex Silver Compounds with (Prof. P. Rây), 643
Tetra-Arylazadipyrromethines, a New Class of Synthetic Colouring Matter (Dr. M. A. T. Rogers), 504
Textile Threads : Abrasion Tests for (A. C. Walker), 113
Textile Research (Synthetic) in Germany, 115
Theory (A Physiological) of Colour Perception (Prof. Ragnar Granit), 11
Theory of Dielectric Breakdown (Dr. H. Fröhlich), 339
Theory of Large Elastic Deformations (Dr. L. R. G. Treloar), 616
Theory of the Fundamental Particles of Physics : Recent Advances in the (Sir Ralph Fowler), 628
Theory of the Liquid State : H. L. Calendar and the (Dr. R. S. Silver), 588
Theory of Numbers : Guide to Tables in the (Derrick Henry Lehmer), *review* by Prof. L. J. Mordell, 64
Theory of Sea Waves (P. J. H. Unna), 479
Theory and Practice of Heat Engines (D. A. Wrangham), *review* by Dr. O. A. Saunders, 571
Thermal Insulation at Medium Temperature (A. C. Pallot), 593
Thermionic Tubes : High Frequency (Dr. A. F. Harvey), *review*, 655
Thiamin from Cooked Potato : Loss of (Dr. Jane Meiklejohn), 81
Think ? : What Ought we to (Dr. Ranyard West), 684
Thinking (My Self, My), My Thoughts (K. W. Monsarrat), *review* by Dr. J. Leycester King, 150
Thiuram Sulphides, etc., in Spore Germination Tests : Behaviour of (H. B. S. Montgomery and Dr. H. Shaw), 333
Thoughts (My Self, My Thinking, My), (K. W. Monsarrat), *review* by Dr. J. Leycester King, 150
Threads (Textile) ; Abrasion Tests for (A. C. Walker), 118
Thunderstorms by a Radio Method : The Determination of the Location and Frequency of (J. S. Forrest), 285
Ticks : Transmission of Leprosy by (Dr. H. Souza Aranjo), 337
Tides : The Solway, 51
Timber in Rhodesia : Preservation of (R. H. Finlay), 423
Timbers (Empire) : Handbook of, War Emergency Supplement (edited by H. A. Cox), 732
Timbers (Indian) : Identification of, 669
Time and Space : Absolute (Dr. G. Burniston Brown), 85
Tissue (Leaf Palisade) : Factors in the Production of (R. W. Watson), 113
Tissue Growth : Pantothenic Acid in (H. McIlwain), 56
Tissues : Electron-Microscopic Examination of (Fritiof Sjöstrand), 725
Tissues (Living) : Physiological Action of Acetic Acid in (Sir Joseph Barcroft, Rachel McNally and Andrew Phillipson), 304
Titania (Melanconis, Pseudovalsa, Prosthecium and) : A Revision of (Lewis E. Wehmeyer), *review* by E. W. Mason, 208
Tobacco : Formation of Nicotine in Plants Grafted on (A. Shmuck, A. Smirnov and G. Ilyin), 338
Tomato (Cultivated) : The Evolution of the (Dr. L. C. Luckwill), 300
Tools (Simple Stone) : An Unrecorded Method of Manufacturing Wooden Implements by (C. B. Mountford), 56
Torque of Soft-Iron Electrical Instruments (Dr. C. V. Drysdale), 423
Town and Country : The Air we Breathe in (Dr. G. M. B. Dobson), 165 ; (Dr. G. M. B. Dobson and Dr. A. R. Meetham), 324
Town-Planning and the Small Sewage Purification Plant (Dr. Ll. Lloyd), 475
Toxicity of Stilbamidine Solution on Exposure to Light ; Increase in (Dr. H. J. Barber, R. Slack and E. Wien), 107
Toxicity of Urea Stibamine : Antimony Content and (R. C. Guha, N. K. Dutta and Dr. B. Mukerji), 108
Toxins (Potent) by *Shigella dysenteriae* (Shiga) in a Synthetic Medium : Production of (Dr. L. Olitzki and P. K. Koch), 334
Trace Elements : Absorption and Excretion of (Miss E. M. Widdowson and Dr. R. A. McCance), 80
  in relation to Health (Nutrition Society conference on), 28
  in relation to Diseases of Plants and Animals, Significance of (Dr. H. H. Green), 28
  in Soils and Grasses, Distribution of (Dr. R. L. Mitchell), 28
  (Cobalt and other) in relation to Disease in Australasia (Sir Charles Martin), 29
  (Copper, Zinc and other) in relation to Physiological Function and Enzyme Systems (Dr. H. Mann and Prof. D. Keilin), 28
Trade (International) : Evolution of (Prof. A. G. B. Fisher), 500
Trade (World) : The British Way in (Dr. Alec L. Macfie), *review* by R. Brightman, 543
Trade Unionism : British (Dr. J. Kuczynski), 446
  and Scientific Workers, 446
Tradescantia : Cytology of *Rhoeo discolor* and (P. N. Bhaduri), 56
  Effect of Irradiation on (D. E. Lea and D. G. Catcheside), 338
Training for the Building Industry : White Paper on, 427
Training of Civil Servants, 361, 511
  R. Assheton appointed chairman of a committee to consider the, 361
Training for Industrial Management (Institute of Industrial Administration conference on), 221
Transformations : Asymmetric (Dr: M. M. Jamison and Prof. E. E. Turner), 391.
Transit of Mercury on Nov. 11–12, 1940 (G. M. Clemence and G. C. Whittaker), 57
Transmission-Line Design : Some Problems in (A. Burke), 106
Transmission Lines : Larch and Scots Pine Poles suitable for, 194
Transpiration (Apparent Photosynthesis and) of Apple Leaves : Effects of Leafhopper Feeding Injury on (G. E. Marshall, N. F. Childers and H. W. Brody), 477
Trawling and the Stocks of Fish (Dr. E. S. Russell), 323
Treatment of War Wounds : Pathology and (Sir Almroth E. Wright), *review* by Prof. A. A. Miles, 209
Tree Seed (Forest) of the North Temperate Regions, with Special Reference to North America (Henry Ives Baldwin), *review* by T. Thomson, 93
Tree-Stump Clearing : Hedge and (T. Swarbrick), 78
Trees : Walnut (Alexander L. Howard), 705
Tribe (Primitive) : Wooden Implements of a, 56
Tribolium destructor Uyttenboorgaart (Coleoptera, Tenebrionidæ) : Effect of Parental Feeding on the Rate of Development and Mortality of (J. M. Reynolds), 55
Trinidad and Tobago ; Annual Report of the Conservator of Forests for 1941, 284
Tripoli (Cyrenaica and) : Ancient Monuments of (Prof. J. L. Myres), 381
Tropical City : Sewage Treatment in a (Dr. Ll. Lloyd), 646
Tropical Sky, The (Compiled by H. E. Watson), *review*, 378
Trout (Brown) (*Salmo trutta* L.) in Alkaline and Acid Waters : Growth of (A. E. J. Went and Winifred E. Frost), 26
Truth: Science, Christianity and (Rev. Canon A. E. Baker), review by the Rev. J. C. Hardwick, 710
Tuberculosis : in Peru (Dr. Ricardo Martinez), 557
  Alcohol and (Dr. Emil Bogen), 477
Tumour Cells : Origin of Malignant (Dr. P. C. Koller), 244
Tumour Growth : Inhibition of (J. H. Thompson, P. F. Holt and H. J. Callow). 364
Turkish Earthquakes, 19
Turkish Undergraduates in Britain to study British machine, electrical and mining engineering, 724
Typhus (Murine) in Bogotá (Dr. Luis Patino-Camargo), 445

ULTIMA THULE, Further Mysteries of the Arctic (Vilhjalmur Stefansson), *review* by Squadron-Leader J. N. L. Baker, 264
Ultra-Short Radio Wave Propagation (Dr. R. L. Smith-Rose and Miss A. C. Stickland), 31
Ultra-Violet Radiation : Magnetization of Matter by (S. L. Martin and A. K. Connor), 167
Ultracentrifuge, The (D. A. MacInnes, W. J. Archibald, J. W. Beams, W. B. Bridgman, Alexandre Rothen and J. W. Williams), *review* by J. St. L. Philpot, 485
Unemployment : The Problem of (Unilever Ltd., and Lever Brothers), 344
United Nations and the War Effort : Scientists of the (Association of Scientific Workers conference on), 58
United States : An Anthropologist Looks at the, *review* by Prof, H. J. Fleure, 405
  Cancer Control in the (Dr. A. Scheele), 668
  Commemoration of Copernicus in the, 221
  Domestic Economy of the (Committee of the Editors of *Time*, *Life* and *Fortune* Report), 343
  Infant Mortality in the (Herbert J. Sommers), 193
  Meteors Seen in the, 192
  Changes in Mortality-Rates in the (Harold F. Dorn), 639
  Post-War Planning of Psychology in the, 677
  Research in the (Sir Ernest Simon), 693
  Organisation of Science in the, 207
  Science and the War Effort in the, 389
  Rural and Urban Areas : Hospital Admissions in (Selwyn D. Collins), 303
Universe : Chance, Freewill, and Necessity in the Scientific Conception of the (Prof. E. T. Whittaker), 612
  The Structure of the (Sir James Jeans), 490
Universities : Function and Future of (Association of Professors and Lecturers of Allied Countries in Great Britain conference on). 466
  Government Grant to, 165
Universities and Reconstruction, 147
Universities in World Education : The Place of the (Miss H. Wodehouse), 148
University Education : Future of (Prof. J. A. Crowther), 171
Unknown Land, An (Viscount Samuel), *review* by R. Brightman, 121
Urals, Behind the : an American Worker in Russia's City of Steel (John Scott), *review* by Dr. David Williams, 516
Uranium/Lead Ratio : The 'Age' of Terrestrial Matter and the Geochemical (F. F. Koczy), 24
Urea Solution (Aqueous) : Long-Chain Molecules in (Dr. R. E. D. Clark), 642
Urea Stibamine : Antimony Content and Toxicity of (R. C. Guha, N. K. Dutta and Dr. B. Mukerji), 108
Urea Synthesis in Mammalian Liver (Dr. H. A. Krebs), 23 ; (Dr. S. J. Bach and S. Williamson), 23
Urinary Extracts : Growth Stimulators in (J. H. Thompson, Dr. P. F. Holt and Dr. R. Forbes Jones), 23
Urine and Plasma from Normal and Hypertensive Subjects : Pressor Substances in (Prof. U. S. v. Euler and T. Sjöstrand), 168
δ Ursæ Majoris: Variation in (F. M. Holborn), 165. 331; (N. F. Knight), 165, 331
Uses (New) for Glass (Prof. W. E. S. Turner), 173 ; *errata*, 194
U.S.S.R. : The Academy of Sciences of the, Programme for 1943 (Alexander Baikov), 129
  Biogeochemical Research in the (A. P. Vinogradov), 659
  Organization of Science in the, 207
  People's Commissar for Education in the, Institution of Newton scholarships for Soviet university students, 106
  Theoretical Physics in the, during the Past Twenty-five Years (Prof. Dmitry Ivanenko), 293
  Vitamin Production in the, 105
  in War-time, 50
  Wartime Science in the (Dr. David Shoenberg), 154
Utilization of Glass, 173 ; *errata*, 194

VACUOLES (Liver) and Anoxæmia (Dr. O. A. Trowell), 730
Valve Technique in Subatomic Research, *review* by Dr. L. Jánossy, 377
Vao: Stone Men of Malekula (John Layard), *review* by Dr. H. G. Baynes, 711
Vegetables : Development of Penicillium on the Cut Surfaces of Certain (W. A. R. Dillon Weston and R. Eric Taylor), 54

Vegetables (Dehydrated) : Stability of Ascorbic Acid in (Dr. W. R. Aykroyd), 22
Velikie Bolgary : Excavations at (Prof. Alexey Smirnov), 300
Venereal Disease (Major J. Marshall), 46
Venereal Disease in Britain (Sydney M. Laird), *review*, 683
Venereal Disease Control (Colonel Edgar Erskine Hume), 445
Venereal Diseases in Peru : Control of, 79
Venezuela : Maternal and Child Welfare in (Dr. Pastor Oropeza), 221
Ventilation of Electrical Substations (F. Favell and E. E. Connon), 500
Vernalization of Lettuce (A. C. Simpson), 279
Vertebrate Eye and its Adaptive Radiation (Gordon Lynn Walls), *review* by Prof. H. E. Roaf, 236
Vessels : Rat Infestation on (Dr. Robert Oleson and G. C. Sherrard), 499
Veterinary Anæsthesia (Prof. J. G. Wright), 723
Victoria : Potato Virus Diseases in (J. G. Bald and A. G. Pugsley), 501
Vienna School : British Medicine and the (Dr. Max Neuburger), *review* by Dr. J. D. Rolleston, 461
Views (News and) from the Scientific Front (Sir Richard Gregory), 517
Vigour (National) and the Temperate Zone, *review* by Prof. H. J. Fleure, 431
Virus-infected Plants : Cytoplasmic Inclusions in (B. Kassanis and F. M. L. Sheffield), 337
Viruses : Immunity to (Royal Society of Medicine discussion on), 551
"Vis et Præterea Nihil"—The Psychology of a Dynamist, *review* by Dr. J. Leycester King, 150
Vision : Light and (Sir John Parsons), 638

MACHINERY OF GOVERNMENT

METHODS AND MEN

RECENT criticism of the Civil Service, so far as it is not superficial or biased, is largely an expression of a fundamental concern with the whole machinery of government in Great Britain. That concern has been fed from numerous sources : for example, the examination of our whole organization of production and supply for war purposes, and the related question of the general direction of our war effort ; the difficulties raised by the recommendations of the Scott and of the Uthwatt reports and in attempts to co-ordinate the planning of reconstruction. The statement on a national policy for industry issued by a group of industrialists, following on Mr. S. Courtauld's paper on "Government and Industry" in the *Economic Journal*, stimulates further thought on the mechanism by which the necessary control of industry is to be exercised, a field to which Prof. Cushman's admirable study of the Independent Regulatory Commissions has directed attention in the United States. The report of the President's Committee on Administrative Management is another stimulus to fundamental thinking about the functions and machinery of government which can fairly be compared with the Haldane Committee's report on the Machinery of Government in Great Britain.

The Planning group (P E P) has, of course, addressed itself to the problem, and the fundamental issues were well stated in the broadsheet issued in July 1941, though that was limited to the Civil Service itself. So far as the Civil Service is concerned, there are two fundamental aspects to be considered—methods and men. First, are the methods in use in the Civil Service to-day adapted to handle the new and wider range of problems with which it is called upon to deal in the service of a new and more positive conception of government ? Secondly, is its personnel, by recruitment, training and tradition, competent to handle those questions constructively, imaginatively and efficiently ? A committee of Ministers and an inter-departmental committee of permanent heads of departments is understood to be at work considering, *inter alia*, the machinery of government. The men who are in charge of departments, with all the prejudices and interests as well as the duties of their office, are so clearly the wrong men to conduct such a survey at the height of their war-time activity that far less value is likely to be attached to their findings than to those of the Sub-Committee on the Reform of the Civil Service appointed by the Industrial and Social Reconstruction Committee of the Liberal Party, or of the Sixteenth Report from the Select Committee on National Expenditure, which deals with the organization and control of the Civil Service.

The Sub-Committee presenting the former report had as its terms of reference : "to consider Civil Service Reform in relation particularly to the allegation that the Civil Service as at present constituted has proved wanting in the powers of rapid decision and action". It gives a glance at the question as to what machinery more suitable than the Civil Service can be found, where in the interests of the community as a whole it is necessary to remove particular industries or undertakings from private profit-making to public ownership or control, but the major part of the report is concerned with the reforms required in the pre-war Civil Service to modernize it and bring it more into line with the modern art of administration. That is also the main theme of the Select Committee's report, which, however, passes over the question of administration of nationalized industry, but includes a survey of the functioning of the Central (Technical and Scientific) Register and the General Appointments Register of the Ministry of Labour and National Service and a review of professional and technical staffs in Government Departments.

The Sub-Committee of the Liberal Party opens its report with a review of the pre-war Civil Service and, as in other recent reviews of this matter, tribute is paid to the excellence of the Civil Service for the purpose for which it was originally designed. That much has never been in dispute. The difficulties arise from the fact that it was not contemplated when the Service was created that it would ever be called on to engage in trade directly, to control in detail the processes and operations of commerce, or be responsible for social services and direct contact with individual services. It was instituted to serve fundamentally a negative conception of Government, and the characteristic defects which it has tended to develop have to some extent rendered it inherently unfitted to serve the more positive conception of government to-day.

While this is true, it must also be remembered that its defects are minor compared with the virtues of its freedom from corruptibility and its devotion to the State, as opposed to party or personal interests, and they are also due not so much to the Service itself as to what public opinion insists upon in connexion with it. The policy of safety first is a direct result of insisting that every action of every Civil servant at every hour of the day shall be open to challenge. Furthermore, the Civil Service to-day is the product of Governments which in recent years have been characterized by an unparalleled timidity, vacillation and lack of vision. This inevitably accentuated the bias of the Service to expose the weaknesses, risks and disadvantages of new proposals, rather than to seize what was good in new ideas and embody them enthusiastically in speedy and decisive action.

The tendency to refer to higher authority by minute, and of higher authority to evade or postpone the issue or to consult other authorities before coming to a decision, is thus inherent in the system of Parliamentary questions. Accordingly, among its important recommendations to speed up and modernize the service, the Committee suggests in regard to this first point, while upholding the principle of Parliamentary questions, that reform might proceed through a recognition both in Parliament and in the Civil Service that modern government is too complex a subject for the simple device of the Parliamentary question to be equally applicable to all aspects of it.

Whether or not new mechanism is required to make ministerial responsibility effective without impairing the efficiency of the administrative machine, it is essential to maintain that responsibility. Some of the criticism of the system of public utility corporations has been on this very point of nebulous ministerial responsibility, although it is admitted that the system has to a large extent withdrawn the staffs from the constant stream of Parliamentary criticism. Until such fundamental issues are resolved, however, mere reforms in the method of recruitment of the Civil Service, in training and grading or in operating methods are unlikely to secure a keen and vital Service characterized not only by integrity and the capacity to take a wide view, but also by initiative and the readiness to accept responsibility.

In regard to recruitment, the Liberal Party's Sub-Committee recommends that the practice of grading entrants to the Service by their method of entry should cease and that there should be a system of post-entry training. Engineers and other professional specialists should no longer be regarded as inferior in status to administrative officers and should be remunerated on a scale sufficient to attract officers able to meet on an equal footing the leaders of their respective professions outside. They should be regarded as available for administrative posts. In the senior grades, there should be much more emphasis on systematic interviewing, and provision for an adequate inflow of officers from the lower grades.

With this insistence on a complete ladder from the bottom to the top, the Sub-Committee stresses the importance of post-entry training. The absence in it of a centrally prescribed scheme of training for officers after their entry is a fundamental weakness of the present Civil Service—though a like criticism might equally be advanced of much of the industrial organization of Great Britain. The Sub-Committee recommends the institution of such central courses of instruction by the Civil Service Commission, as well as of departmental courses, and it advocates strongly the establishment of a staff college for the Civil Service analogous to the staff college for the Army, through which those officers likely to be the future holders of the highest posts in the Service should pass. The Committee, moreover, is unanimous that if such a college for teaching, in effect, the art and science of administration were established for industry and commerce generally, it would be even better that the selected Civil Service officers should pass through it than through one established for the Civil Service only. This proposal should meet Sir Warren Fisher's objection that a staff college would accentuate the academic character of the Service. Contact in this way with the future leaders of commerce and industry should facilitate a better understanding of the needs and outlook of commerce and industry and check the narrow professional outlook sometimes attributed to the present Civil Service.

This proposal for a staff college, already advanced by P E P in its broadsheet, is reiterated by the Select Committee on National Expenditure, which makes the same point as to the importance of actual contact in this way of the Civil Servant with commerce and industry and with the work of local authorities, public utility companies, social services, etc., and in particular with those levels of government activity at which Departments come into direct touch with the life of the community, such as the Inland Revenue and Public Assistance. The training thus provided should be of special value in helping to meet the increasing demand for promotion to the administrative grade of selected members of the executive and clerical grades. The Select Committee considers that, subject to tests of character, ability and merit, opportunities of graduating to positions of authority should be open to those who qualify from the school of experience in the Civil Service, equally with those whose qualifications are mainly academic. Moreover, it stresses the value of such a project in providing the training and opportunities needed by Civil Servants who wish to specialize in organization and methods of work.

Beyond this recommendation, the Liberal Party's Sub-Committee contemplates a complete reorganization of the Civil Service Commissioners and wide extension of their powers. It endorses emphatically the recommendation of the Planning broadsheet regarding the divorce from finance of the management and control of personnel. This is regarded as a central function, which cannot properly be discharged by any special department such as the Treasury, and it recommends that the present Civil Service Commissioner's Department should be made into a true central department by removing it from the control of the Treasury, and making it directly responsible to a Minister without Portfolio, who should be the Deputy Prime Minister. The present Establishment Branch of the Treasury would be transferred to the re-organized department, which would be staffed as soon as practicable with officers trained in the modern technique of management. Much importance is attached to method of selection and term of tenure of office of the permanent head of the re-organized Commission. This appointment should be made from within or without the Service by the Prime Minister on the advice of the Minister immediately responsible, and of an advisory committee independent of the Service, and tenure of the office should not exceed five years. As in the report of the Planning group, the importance of eliminating unsuitable officers at any stage in their career is emphasized, while caution is advised in regard to the introduction of outside blood in the more senior grades, on account of the dangers of political pressure and nepotism.

If the Liberal Party's Sub-Committee has relatively little to say about welfare work and office planning, though their importance is noted, the latter in particular is a main theme of the Select Committee's report, which is very largely a review of the whole work of the Organization and Methods Division and the re-organization of the Treasury in regard to the control of the Civil Service. It points out that, following the recommendations of the Haldane and Bradbury Committees, an Establishment Department was erected within the Treasury and establishment officers appointed in most Departments of State throughout the period 1919–39; nevertheless there was no overt sign that the Treasury or the departments accepted the proposition that the organization of administrative machinery was a subject requiring expert and specialized study, or that any lessons in the art of management could be learned from industry and commerce either in Great Britain or abroad. As a result of this twenty years of neglect, the outbreak of war found the Treasury insufficiently equipped to deal with the problems of administrative organization which were forced upon it. There was no core of expert knowledge which might have been built up if the systematic and periodical overhaul of the whole of the machinery of government had been undertaken. Such a body of knowledge might at least have supplied standards by which proposals concerning the staffing of new and expanding departments could have been examined and tested.

The Select Committee considers that control of establishment matters should continue to be exercised from the Treasury for three reasons. First, risk of duplication and waste through the interposition of a new authority between departments and the Treasury, because the Treasury's control on expenditure would still remain. Secondly, it is convinced that the advantages arising from the central position of the Treasury, with its unique knowledge of the general activities of Government, should be retained and utilized. Thirdly, it considers that the view that the association of the functions of finance and supply with those of establishment is bound to be detrimental to the interests of the latter is ill-founded. It bases its recommendations on a conception of economy which is identical with the promotion of efficiency. The ideal control of the Civil Service must be regarded as concerned with the systematic study of the means and methods by which the work of government may be carried out with the maximum efficiency and the minimum waste of time and money. Recommendations are accordingly made for improving the organization of the Treasury.

It is not necessary to accept without question the Select Committee's argument for the retention of Treasury control in order to appreciate the lucidity and precision with which the essentials of the problem are laid bare. The value of that analysis is unaffected whether the ultimate decision is to retain Treasury control or to establish a new central department, as suggested in the report of the Liberal Party's Sub-Committee and elsewhere. The Select Committee's own opinion, however, that, so far as the Treasury was concerned, the period from 1919 until 1939 was marked by an almost complete failure to foster the systematic study of organization as applied to Government departments is possibly the strongest argument against its own recommendation. The re-organization suggested cannot wisely be left in the hands of the same men or in those of similar outlook.

Fundamentally, the problem is one of men and not merely of methods. In any event, either plan of reform might prove equally effective, given men of the requisite imagination, personality and ability. The effectiveness of a staff college, for example, depends on the type of men who teach there, and the vital purpose by which it is informed, and there is no *a priori* reason why a Treasury Department, staffed by men of the right outlook and understanding, should not prove brilliantly successful in securing that the machinery of government is maintained at the highest efficiency and adapted continuously to the purpose to be served. Sir Warren Fisher is unquestionably right in stressing the importance of the problem of the selection of men. As the Select Committee points out, however, expert knowledge of organization is not a monopoly of business men, and it does not regard the commercial world as even the principal source from which efficient organization officers should be recruited. There is a considerable field of recruitment among existing Civil Servants, many of whom possess the vigorous personality and the profound conviction that the study of organization and methods is worth while.

In the long run, however, the spirit and efficiency of the Civil Service are a reflection of the temper and interest of the community it serves. No matter what machinery we devise, we cannot expect a Civil Service of the highest ability and integrity, imbued with vision, initiative and enthusiasm, unless there is mutual understanding and respect between the Service and the community whose interests it serves and safeguards. The biased and irresponsible attacks on the Service by those seeking to promote their own selfish interests under the cloak of a return to the old intolerable muddle of *laisser-faire* do disservice to the State as well as to the Civil Service. It is a great merit of this sixteenth report of the Select Committee on National Expenditure—a report which may well take its place as a great State paper alongside the Haldane Report on the Machinery of Government for its creative analysis—that it provides not only a critical appreciation of the Service, for which Civil servants themselves should be grateful, but also an interpretation of the Service which should promote good understanding and closer and more fruitful co-operation between Whitehall and the public. Here is indeed trenchant criticism and the searching exposure of weaknesses. Here, too, is generous appreciation of good qualities, and an attempt to hold the balance and apportionate blame or responsibility fairly.

No one who attempts to think constructively and creatively about the exceedingly complex problems of modern government, the machinery to be called into being to serve the purposes of the War or of reconstruction in the new order to follow, can disregard this report and its elucidation of some of the fundamental issues upon which our machinery and our philosophy of government must be based. The wide interest in the larger questions of the general control and organization of the Service and the construction of further machinery to increase its efficiency displayed in the recent House of Lords debate, where Lord Hankey lent the weight of his authority to propositions substantially the same as the recommendations of the Select Committee, is one of the happiest indications that we are applying ourselves to a task which will tax the best ingenuity as well as the utmost intellectual resources of either British or American democracy, and in which each democracy may well contribute much towards the solution of the other's particular problems.

A GREAT ETHNOLOGIST

Haddon, the Head Hunter

A Short Sketch of the Life of A. C. Haddon. By A. Hingston Quiggin. Pp. xii + 169 + 7 plates. (Cambridge: At the University Press, 1942.) 7*s*. 6*d*. net.

Born in 1855, A. C. Haddon died at the age of eighty-five in 1940. He richly deserves this exquisitely written life-history. For he achieved a great work and he was endowed with a unique personality. In the selection of her abundant material, Mrs. Quiggin is to be congratulated on her wise judgment. She knew Haddon intimately from the year 1904 when she began to help him, not only in secretarial work, but also in "the concocting of syllabuses and lecture notes, the abstracting of papers, the making of lantern slides and the writing of minor reviews".

Her sketch of his life is not overwhelmed, as so many biographies are, by excessively long extracts from correspondence. She throws much light on his ancestry and early life, which will be welcomed to-day by those who only knew him in middle-age and later. He was descended from three generations of John Haddons, all most ardent Nonconformists, the first a gentleman-farmer of Naseby, the second who founded in 1814 the printing firm of John Haddon & Co. in London, and the third who, failing to inherit the business abilities of his father, allowed the prosperity of the firm to suffer until he was supplanted in 1888 by an abler cousin. The thus dwindling fortune of A. C. Haddon's parents caused frequent family removals from suburb to suburb. It was his fate to be sent to "any school which happened to be in the neighbourhood", and he thus received but a scrappy and desultory formal education. When quite a child, he showed his first interest in acquiring skulls. By then he had already begun to collect minerals, plants, butterflies, eggs, etc., and soon he became busy with dissection and microscopy. At the age of fifteen, he entered the family printing office, where he served five years of "duty and drudgery", hating the work, until his father fortunately came to realize that it would be more economical to send his son to Cambridge, as he would never make a business man of him.

At Cambridge Haddon came under the influence of Michael Foster, McKenny Hughes, Alfred Newton and especially of Frank Balfour, "his beloved master and friend", as he styled him, in a subsequent dedication of his first book, an "Introduction to the Study of Embryology". From his childhood he had shown a fondness for sketching; and while at Cambridge he attended the lectures on art of the Slade professor, Sidney Colvin. This early interest in design was to receive later development in an unexpected scientific direction. He met at Cambridge Holland Rose, a fellow undergraduate, later the distinguished Napoleonic historian, who married Haddon's younger sister. Haddon was appointed professor of zoology in the Royal College of Science, Dublin, in 1880; and a year later he married Rose's sister, whose devotion as mother and wife, self-sacrifice and courage throughout her husband's many hardships and disappointments made her a perfect helpmate.

At Dublin, Haddon felt himself soon "perishing for want of research". He became more and more dissatisfied at having to lecture on coral reefs and tropical fauna which he had never seen. So, in 1888, on T. H. Huxley's advice (who had already visited this region in the voyage of the *Rattlesnake*), he spent a year in the Torres Straits. He went out as a zoologist; he returned as an ethnologist, destined to conduct, eleven years later, that second expedition to the Torres Straits, which earned him such well-deserved fame.

From 1893 he made his home at Cambridge, although retaining his zoological professorship in Dublin until 1901 in order to 'keep the wolf from the door'. His energy, both physical and mental, was throughout his life extraordinary. At Cambridge he at once began to teach physical anthropology, although he received no university stipend and held no university post. His first lectures and practical courses were offered to candidates for the second part of the Natural Sciences Tripos in human anatomy and physiology. I attended the first course in 1893–4, and well recall the care with which his lectures had been prepared and the wonderful skill and enthusiasm he displayed in teaching. Mrs. Quiggin is well justified in her observation: "It may be that his work as a teacher was even greater than his work as a scientist, for he had the gift of inspiring others, and his students have carried his ideals with them to the ends of the earth". The effect, at all events, upon me of my attendance at Haddon's first classes in anthropology at Cambridge was that I became immediately (before taking my degree) engaged on craniometric research, reporting on a collection of ancient British skulls recently acquired by the Anatomical Museum.

In my opinion, Haddon's most natural bent towards the science of ethnology lay in the direction of the study of native arts and crafts—technology. His fundamental contribution to this subject appeared in 1895 when he published "Evolution in Art", which became, as his biographer says, "an unexpected best-seller". He vainly hoped to issue it later in a revised form, embodying much of the immense material afterwards collected. His later works on the stone clubs of British New Guinea, the canoes of Oceania, the decorative art and fabrics of the Sea Dayaks, etc., arouse an intense, righteous anger, because one so eminently fitted to devote himself to this important aspect of ethnology should have felt compelled to spend his time unduly in writing newspaper articles and reviews, in acting as referee to various publishing firms, and in giving lectures throughout the country, in order to 'make ends meet' financially with his growing family of a son and two daughters. Whether or not they persisted sometimes needlessly as a habit, these activities certainly helped to arouse general interest in so young a subject; and anthropology would not have been what it was when Haddon left it had he not felt forced to give so much of his time to its popular nurture.

That he was a successful organizer is patent to anyone familiar with the success of his *chef-d'œuvre*, the Cambridge Anthropological Expedition to the Torres Straits and Sarawak, most of all to one who, like myself, was a member—now the last surviving member—of it. From start to finish of the Expedition and of its work, not a cross word escaped him; what he wanted was done because, under his inspiring and enthusiastic leadership, everyone realized the justice of it. From this expedition he returned in 1899 to find that a successor had been installed in his place, holding the £50 lectureship in physical anthropology which had been created for him in 1895. In the following year he received, in compensation, an appointment to an equally generous lectureship in ethnology at his old University, which only in 1909 raised it to a readership with a stipend of £200. By this time he had been elected to a fellowship at his old college, Christ's, and had been tempted to accept another distraction, the Martin White lectureship in ethnology in the University of London.

His tardy recognition at Cambridge may have been partly due to his unusual personality. "You must be a little mad," he once said, "to get anywhere. You can't advance without overbalancing." "He had no society manners, and his blunt, downright outspokenness was often disconcerting in conventional circles." He rather enjoyed shocking the 'unco' guid' and the prudish; "those whom he thought insincere or silly often thought him rude". Quite wrongly he was often regarded as being merely pagan or agnostic. But behind lay a strong inherited vein of religiousness, philanthropy and generosity. There was indeed some basis for the verdict of one of his (Christianized) Murray Islanders in the Torres Straits, who described him as being "close up alongside God". He had a wonderful love of humanity and a gift of sympathy with, and understanding of, less cultured people, which made him a unique ethnologist in the field. C. S. MYERS.

COLLOID SCIENCE

Advances in Colloid Science

Edited by Dr. Elmer O. Kraemer, in collaboration with Prof. Floyd E. Bartell and Dr. S. S. Kistler. Vol. 1. Pp. xii+434. (New York: Interscience Publishers, Inc.; London: The Imperial Book Co. Ltd., 1942.) 33*s*.

COLLOID science nowadays covers a multitude of the branches of physical chemistry and even of technology. The diversity of subjects treated in the present volume is as wide as the all-embracing title might lead one to suppose. The editorial viewpoint is that the series shall present recent work in this subject by authors who have made significant contributions. If we may judge from the variety of topics dealt with in the first volume there will be no lack of subject matter for some time to come. One consequence of the editorial policy will be that the articles will often contain the individual opinions of the authors and that they will be more in the nature of progress reports than chapters in a text-book. But this fortunately leads to a more stimulating treatment, provided the reader has already some knowledge of the subject under review.

An ever-recurrent problem in technology is the development of a rapid method of determining the state of subdivision of a powder. Usually all that is required is a measurement of the specific surface or perhaps a mean value for the radius of the constituent particles. Microscopic methods are too laborious, and sampling is difficult. P. H. Emmett gives a review of his own work in which the proper interpretation of the adsorption isotherm of selected gases or vapours provides the basis for computing the specific surfaces of the adsorbent. Provided the particles of adsorbent do not have a porous structure a measure of the mean diameter may thus be obtained. Another method of measuring specific surface consists in determining the resistance to the flow of fluid through a plug of powder. Again the technique is not easy, but R. R. Sullivan and K. L. Hertel carefully point out the limitations of the method as compared with existing alternatives. These articles fortunately contain sufficient experimental detail to render them useful as working guides in the laboratory.

Differential adsorption has been brought to a high state of perfection in chromatographic analysis. But there is nothing in principle to prevent the method being more universally utilized, and A. Tiselius describes the modification of the technique for dealing with colourless solutions. The analysis, by refraction, of the concentration gradients of the emergent solution enables the several solutes to be separated and recognized. The method was specially developed for amino-acids and peptides; its success here is proof of its sensitiveness and powers of discrimination.

The mechanism of detergent action, discussed by J. W. McBain, is of increasing importance in many technical processes. There is still much to be done to the theory because the search for new detergents is almost wholly empirical in character. The particular aspect of detergent action discussed is the increase in solubility of hydrophobic substances in water brought about by the addition of these agents.

High polymers rightly assume their proper place in colloid science and consequently in this volume. K. H. Meyer discusses in some detail the structure of starch and shows how purely chemical methods have thrown a flood of light on the way in which the glucose units make up the relatively complex molecule. At the other extreme R. E. Powell and H. Eyring survey the possible application of statistical methods to the physical behaviour of high polymers and their solutions. Owing to the complicated nature of the subject only broad generalizations may at present be formulated. Perhaps one of the more interesting is the conclusion that, in the flow of molecules in the molten polymer, segments of 20–25 carbon atoms move as a whole, which movement is independent of the chain-length of the polymer. Much can be learned of the shape of dissolved or dispersed particles by examining the streaming birefringence of their solutions. Again, enough is given of the technique and of the theory to make this article by J. T. Edsall a good starting-off point for those interested in studying the subject further.

A good indication of recent advances in colloid chemistry in the classical sense of the term is furnished by the elucidation of the structure of the gels of metallic hydroxides by following the process of their formation by examination of their X-ray diffraction patterns. H. B. Weiser and W. D. Milligan thereby add another chapter to the investigation of inorganic colloids. Some of the principles of the coagulation of colloidal solutions now find direct practical application to the concentration and precipitation of rubber from latex. G. E. van Gils and G. M. Kraay describe a systematic investigation of those factors which govern the preparation of concentrated and stable rubber latex which now has—or perhaps had—so many important applications in industry.

E. A. Hauser brings forward his pendent drop method for the measurement of surface tension and further discusses rather too briefly some of the anomalies of the surface tensions of solutions.

The removal of ions from natural water is of fundamental importance in the supply of suitable water to boilers, for the efficient utilization of detergents and indeed for most industrial processes (R. J. Myers). Cations are perhaps the most troublesome, and the base exchange zeolites—natural or artificial—provide one of the best methods of coping with this problem. Zeolites are not, however, unique in this respect, since certain phenol formaldehyde resins contain a sufficient percentage of hydroxy groups to react in a manner similar to that of the zeolites. Progressing a stage further, acid-exchange resins from aniline and formaldehyde allow of the removal of anions and their replacement by hydrogen ion. There is thus theoretically the possibility of removing both anions and cations from water by a two-stage process—in fact, it now is a commercial proposition for the preparation of 'ion-free' water.

It appears to be a far cry from colloid science to electron optics, but the fact is that the electron microscope bids fair to become a useful tool for the investigation of disperse matter lying in the range 0·01–10 μ. T. F. Anderson gives enough in his article to whet the appetite for more and to convince the colloid chemist that an electron microscope is even more useful than the ultramicroscope of classical colloid chemistry.

H. W. MELVILLE.

MUSEUM PRESENTATION OF GEOLOGY

Geology in the Museum

By Dr. F. J. North, C. F. Davidson and Lieut. W. E. Swinton. (Published for the Museums Association.) Pp. viii + 104 + 6 plates. (London: Oxford University Press, 1941.) 5s. net.

POST-WAR reconstruction promises to extend to museums, demanding from them not only rehabilitation after the neglect of the war years but also extended activities along both recreational and educational lines. Aims must be re-examined, collections overhauled or replaced, and exhibitions devised anew. Museum officials, amply supplied with textbooks on systematics, have hitherto been forced to delve laboriously in professional journals in search of papers on museum problems of preservation and presentation. For their especial needs, the Museums Association is publishing a series of handbooks, and that under notice surveys geology in the museum.

Dr. North deals with the general problems of the introduction of geology to a varied public; Dr. Davidson contributes a section on mineralogy; and Dr. Swinton completes the trilogy with one on palæontology. Notes on what to collect are followed by others on treatment and preservation, on registration and storage. The exhibition aspect of geology is prefixed by a discussion of aims, of what to show and how to show it, together with a consideration of layout and labelling, of diagrams, models and other adjuncts. Details of materials and instruments, recommended by past experience for future use, and the sources from which they can be obtained are given in text and footnote. Consideration is given to furniture and equipment, both for exhibition gallery and for staff laboratory. The bibliographies are carefully selected and up-to-date. While this little volume cannot make a curator a geologist, it will help to make a geologist a curator. D. A. A.

EVOLUTION IN ASTRONOMY*

By SIR JAMES JEANS, O.M., F.R.S.

ONE of the most important, and also one of the most fascinating, of the problems of astronomy is the tracing out of the steps by which the universe has evolved from primitive beginnings to its present complex form. But until recently it was like trying to piece together a jig-saw puzzle from which some of the more important pieces were missing. Happily the situation has changed rapidly of late; more pieces of the puzzle have come to light, and one in particular—a better knowledge of the possible sources of stellar energy—is found to fit very convincingly into a big vacant gap, with the result that the whole picture begins to assume a logical and satisfying shape.

Most cosmogonies have assumed that the universe began in a state of complete chaos. Newton saw that a mass of chaotic matter spread uniformly through space would form into condensations under its own gravitational forces, and that these would ultimately divide into separate detached masses. He here indicated the first broad lines of cosmic evolution; we are now able to fill in many of the details.

Astronomers have recently made two complementary discoveries which fit together very satisfactorily —that our galactic system of stars is smaller in size than used to be thought, and that the extra-galactic nebulæ are larger. Obscuring matter spread through space dims the brightness of the stars, making them appear more distant than they are; the recognition of this has brought the distant stars nearer and the galactic system has shrunk. Simultaneously, photometric studies of the sky have shown that the extra-galactic nebulæ extend much farther than appears on the photographs from which we used to estimate their dimensions. It is now clear that the galactic system and the extra-galactic nebulæ are all about the same size, their longest diameters perhaps averaging 100,000 light-years.

Their masses also are found to be not very dissimilar. The mass of the galactic system can be determined from the gravitational pull it exerts on the sun and the stars in its proximity; it proves to be rather more than 100,000 million times the mass of the sun. The masses of the extra-galactic nebulæ can be estimated from the gravitational pulls they exert on one another or on other moving objects; estimates of nebular masses range from 20,000 million to 200,000 million suns.

In this way the galactic system and the extra-galactic nebulæ prove to be similar objects, which we may conveniently describe as 'galaxies'. They are scattered fairly uniformly through space at an average distance apart of perhaps a million light-years. If we assume their average mass to be 100,000 million suns, the average density of matter in space is $2 \cdot 4 \times 10^{-28}$, which gives 200 atoms of hydrogen, or one of mercury, to the cubic metre. If the universe is really expanding in the way suggested by the spectra of the nebulæ, this density is continually decreasing, its value being halved every 450 million years. But the density of the primeval chaos must have been at least of the order just mentioned. With this density adjacent molecules are about a foot apart, while the free-path must be measured in light-years.

If we know the density of a distribution of chaotic matter, and the average speed of the thermal motion of its units, we can calculate the average mass of the condensations which will form in it. Newton conjectured that these condensations would be of stellar mass; we now know they would be of galactic mass. Condensations having an average mass of 100,000 million suns would result from a density of $2 \cdot 4 \times 10^{-28}$ and a thermal velocity of 37 km. a second. The thermal velocity might easily have this high value if the chaos contained a good proportion of free electrons, since these have a speed of 111 km. a second at 0° C.

Thus the first step in the evolution of the universe was probably the breaking up of a primeval chaos into the separate masses which now form the galaxies. These are all of the shapes which would be assumed by compressible masses in rotation, and rotation can be observed spectroscopically in the nearer nebulæ. We do not know how it originated—possibly from currents and swirls in the primeval chaos. In any event, as the condensations contracted under their own gravitation, their speeds of rotation would increase and they would assume in turn the shapes appropriate to different rates of rotation. In the last stage of all, matter lies spread out in the equatorial plane of the rotating mass, where it again becomes liable to gravitational break up, and will form detached condensations. On inserting reasonable values for the density and thermal velocity of this matter, we find that the condensations will be of stellar mass. Thus, except for the intermediate step of the formation of galaxies, we can picture the stars as having been formed much as Newton imagined. As the average density of the parent nebula would scarcely be greater than 10^{-22}, the new-born stars will be of very low density; they will perhaps exist as distinct and detached masses while their densities are still as low as 10^{-20}.

They will of course begin by contracting rapidly under their own gravitation; a mathematical theorem of Poincaré helps us to follow their progress. It tells us that the total thermal energy imprisoned in a gaseous star at any time is just equal to the total energy which the star has lost, or would have lost, in contracting from a state of infinite diffusion. Incidentally, we notice that the more a gaseous star loses energy, the hotter it becomes—not the cooler, as we might be tempted to think.

Thus when the size and composition of a star is known, we can calculate its total thermal energy, and so deduce the temperature of its interior. It is found that the average temperature of the sun's interior must be about 20,000,000°, unless the sun contains a large amount of hydrogen, in which case it will be substantially lower. When other stars are treated in the same way, the surprising result emerges that for the largest class of known stars—the 'main-sequence' stars—the average internal temperature must be exactly or very nearly the same as for the sun.

The total energy supplied by gravitational contraction can, as is well known, only provide a small fraction of the total energy which the sun must have radiated even in geological times, and it has for some time been suspected that the sun—and of course the other main-sequence stars also—must draw energy from some source which comes into operation as soon as stellar matter attains a temperature of the order of 20,000,000°. The recent intensive study of nuclear physics has revealed just such a source of energy.

In a famous series of experiments, Rutherford showed that the nuclei of the atoms of the light elements can be transmuted into nuclei which are chemically different through bombardment by α-particles. Now at the high temperatures of stellar interiors, α-particles, which are merely helium nuclei, are a normal constituent of stellar matter, the helium atoms being broken up into their constituent particles by the heat. The stars become alchemical laboratories, in which the chemical elements continually suffer transmutation as their atoms or nuclei are bombarded by α-particles and other swiftly moving projectiles—protons, neutrons, deuterons, and the like.

---

* Substance of a course of lectures delivered at the Royal Institution on November 3, 10 and 17.

Reactions of this type are called thermonuclear. They are mostly very sensitive to changes of temperature, so that each reaction may be associated with a definite critical temperature; below this temperature the reaction occurs only in minute amounts, but above it in torrential amounts. This critical temperature depends very much on the complexity of the nuclei involved in the reaction, being approximately proportional to the square of the atomic numbers of these nuclei. It is consequently lowest—less than 1,000,000°—for the simple reaction of one proton with another. In this reaction a deuteron is formed, and as this leaves an excess of positive electricity, a positron is set free. The deuteron may afterwards capture two more protons and form a helium nucleus.

Next, at temperatures of from 3 to 7 million degrees, protons may react with the nuclei of the light elements lithium, beryllium and boron.

Then, at temperatures of the order of 20,000,000°, comes the reaction of a proton with a carbon nucleus of mass 12. The combination forms a nitrogen nucleus of mass 13, but this is only the first of a series of processes. The nitrogen nucleus may capture a second proton, becoming an ordinary nitrogen nucleus of mass 14, and then a third proton, becoming a nitrogen nucleus of mass 15. This may capture yet a fourth proton, but the result is not a nitrogen nucleus of mass 16; it is usually a carbon nucleus of mass 12, together with a helium nucleus, or α-particle, of mass 4. Actually this description has omitted subsidiary processes which do not affect the final result. The main events consist of the carbon nucleus swallowing four protons in succession, and thereby being pushed along the sequence of nitrogen isotopes until this road comes to an end. It then resumes the form of the carbon nucleus with which it started, the four protons it has swallowed being disgorged in the form of a helium nucleus. In this way four protons are bound together to form a helium nucleus, all the other nuclei emerging unaltered—the carbon has merely acted as a catalyst.

This transmutation may not appear to have any relation to the supply of energy for radiation, until we notice that the total mass of the matter concerned has experienced a diminution. The atomic weight of hydrogen (O = 16) is 1·008, whence the mass of four protons is 4·030, while the mass of the resulting helium nucleus is only 4·003. Thus there has been a loss of mass of 0·027 units, or one part in 150 of the total mass involved.

We know that all radiation has mass associated with it at the fixed rate of 1 gm. for every 9×10^{20} ergs of radiant energy. Thus the sun, radiating $3{\cdot}8 \times 10^{33}$ ergs a second, must lose $4{\cdot}2 \times 10^{12}$ gm. a second—250 million tons a minute. The core of the problem of the source of solar radiation is the finding of mass of this amount inside the sun which is capable of being set free in the form of radiation. Now each thermonuclear reaction in which mass is lost results in an equivalent emission of radiation in the form of γ- or X-rays; these are soon absorbed by the stellar matter and re-emitted as temperature radiation in equilibrium with the stellar matter. Thus thermonuclear processes are fully capable of explaining the sun's radiation qualitatively.

They are also adequate quantitatively. To emit its present stream of radiation for a period of 2,000 million years, the sun must lose one part in 7,500 of its mass; if it consisted wholly of hydrogen (apart from a small amount of carbon acting as a catalyst) it could transform one part in 150 of its mass into radiation by the process just considered. A sun in which only one fifth of one per cent was hydrogen could provide the present sun's radiation for 2,000 million years—and it is fairly certain that the sun contains more hydrogen than this. The evidence of astrophysics is that hydrogen is the most abundant element in most stars.

Other classes of stars present different problems, to which different answers must be given. The most luminous stars of all, apart from freaks, emit about 7,500 times as much radiation per gram of their mass as the sun. Neither thermonuclear reactions nor anything else could enable these stars to radiate at their present rates for 2,000 million years; to do this they would have to transform the whole of their mass into radiation. We must conclude that such stars cannot radiate as at present for another 2,000 million years, and probably have not done so in the past, unless they can draw on external sources of energy, as, for example, by an accretion of matter from outside. The red giants and Cepheid variables, which do not belong to the main sequence, have central temperatures well below the 20,000,000° which characterizes the main sequence stars. The carbon reaction cannot occur in these in appreciable amounts, but it seems likely that reactions with elements lighter than carbon may provide the energy for their radiation. In time, all these light elements will have been used up; the star will then contract, its internal temperature continually increasing, until it reaches 20,000,000°. The star has now joined the main sequence, and the carbon reaction comes into play to supply it with radiation.

Again, the smallest stars have central temperatures well above the critical 20,000,000°. These must have used up all their hydrogen, and then started contracting afresh. The energy they are emitting as radiation may be derived from their gravitational contraction—which could supply radiation for perhaps 100,000 million years—or possibly from some other thermonuclear processes, not yet identified, which occur at temperatures above 20,000,000°.

Certain minor complications, such as have already been mentioned, do not affect the occurrence of the processes, but they ensure the stability of the star. A process in which the generation of energy increases rapidly as the temperature increases is usually unstable. For any slight increase of temperature causes an excess generation of energy, which causes further heat, still more generation of energy, and so on indefinitely; the process becomes explosive. But when, to take a single instance, a carbon nucleus has swallowed its first proton and become a nitrogen nucleus of mass 13, it must emit a positron before it is ready to swallow a second proton. This is emitted by a sort of radioactive disintegration and, as an increase of temperature does not increase the rate of radioactive disintegration, the explosive sequence of events just mentioned does not occur. An increase of temperature will now merely increase the pressure inside the star, so that the star expands and cools. By this thermostatic mechanism, the star continually adjusts itself so that just enough energy is generated to replace that lost by radiation. From its nature the adjustment cannot usually be instantaneous, so it is perhaps not surprising that the stars which are cooler than 'main sequence' stars are mostly variable stars in which regular and substantial fluctuations of light occur.

Thus we think of the matter of the primeval universe as having first condensed to form separate detached masses, one of which ultimately formed our galactic system. This process may well have taken tens of thousands of millions of years. These distinct masses in their turn broke up into separate stars, taking perhaps hundreds of millions of years to do so. These stars would at first be cool, of low density and of immense size. After contracting for a few million years, they attain a temperature at which the proton-proton reaction begins to occur. But at low temperatures this reaction occurs but rarely—too infrequently to make good all the energy lost by radiation. The stars accordingly continue contracting until they attain temperatures at which the protons react to an appreciable extent with the nuclei of light elements. This reaction may supply radiation for a few million years, after which the light elements are used up; then contraction begins afresh and continues until the temperature of 20,000,000° is reached. The carbon reaction now takes control and can supply radiation for thousands of millions of years if the star is not too massive and luminous. During this period, the proton-proton reaction still occurs, and may provide for an appreciable part of the star's radiation—perhaps for half in the sun, and for even more in less massive stars. Finally, the supply of protons gives out, and the star contracts once more—possibly for hundreds of thousands of millions of years.

At some point in this sequence of events the sun has given birth to planets; at some point other stars may do the same. Mathematical investigation shows that planets can be born out of a star by tidal action—through a second star approaching near to it and drawing out a long filament of gas, which then breaks up gravitationally and condenses into separate planets. If the two stars are of similar build, such an event requires an approach to within about three radii, whatever the sizes of the stars may be.

Approaches of the requisite closeness would clearly be far more frequent in the early period when the stars were big, than in the later period when they were compact. For our sun, the first period was short (less than 20 million years), while the latter period has been long (more than 2,000 million years). Nevertheless, calculation shows that an effective tidal encounter is far more likely to have occurred in the former short period than in the latter long period. It is not surprising, then, that the solar system is found to contain intrinsic evidence that its planets were born while the sun was still of immense size. It must have extended an appreciable fraction of the distance to the present orbit of Pluto: otherwise there would have been no mechanism for putting the outermost planets in their present orbits.

It follows from this that the age of the sun as a star is approximately equal to the age of the earth as a planet—probably between two and three thousands of millions of years. In this period, the sun can only have used up a small fraction of its protons, so that it probably can look forward to a life in its present state which will be incomparably longer than the life that lies behind it. When this is over, it will begin to shrink into a smaller and cooler star, and life on earth will become impossible.

Detailed calculations show that the chance that a star shall give birth to planets while it is of the compact dimensions of our sun is quite negligible. On the other hand, the chance of its having given birth to planets before attaining to this state is considerable—a fair proportion of the stars must, then, be accompanied by planets. Of these a substantial fraction are likely to be in a physical state not very different from that of our own earth, and so capable of maintaining life like our terrestrial life; it is possible that such life is far more abundant in space than we used to think.

PREVENTION AND TREATMENT OF ANTI-SOCIAL BEHAVIOUR

IN his Chadwick Lecture on "The Differentiation, Prevention and Treatment of Anti-Social Behaviour Disorders" delivered on December 8, Dr. Norwood East has made a succinct but systematic review of the main established facts regarding the causation of crime, and has presented a convincing argument for the view that crime is as much a scientific as a legal or a medical problem. Dr. East was for many years one of H.M. Commissioners of Prisons, and Medical Inspector of Prisons in England and Wales. He has recently completed a scientific study on an extensive scale of the medical, social and psychological aspects of crime, more particularly among adolescents (see NATURE, September 26, p. 361). He is therefore able to speak both with experience and authority; and much of his lecture is in fact concerned with the practical corollaries to be deduced from the inquiries that he has made.

Generally speaking, Dr. East regards behaviour disorders as manifesting in nearly every case a complex causation. They are "the result of stress, acting upon an inherited constitutional pattern, which may itself have been modified, in varying degrees, by environmental factors other than the stress itself". The inherited constitutional factors are themselves incapable of being greatly changed. It follows that, in general, the treatment of anti-social behaviour must be limited to efforts at changing the environmental factors, and particularly to relieving whatever stress may have precipitated the criminal action. In different cases, however, the relative importance of the constitutional factors, on one hand, and of the environmental factors, on the other, may differ widely. Thus, although individuals belonging to certain temperamental types may be more liable to yield to temptation than persons of average mental heredity, nevertheless, "the majority of persons, and perhaps all, are potential first offenders"; for criminal action, as a rule, results, not from one type of factor to the exclusion of the other, but from "a disturbance of the balance between the two".

According to Dr. East, therefore, the fundamental psychological premise from which the criminologist has to start is the fact that "no person corresponds exactly to his fellows; for even an arbitrarily selected normal person occasionally shows peculiarities of behaviour". Consequently, while anti-social behaviour may be precipitated by almost any form of maladjustment between the individual and his environment, some individuals, by nature or by habit, will be more prone to disregard the requirements of the society in which they live, and so more easily led into actions which that society regards as criminal. This is especially true of those suffering from mental defect or mental disease. Much of his lecture is, therefore, devoted to the relation of crime to these particular pathological conditions.

Among inborn factors, the most important in his view are the inherited "drives", a term which he borrows from American psychologists to denote "the impulsive energy of any instinct". In guiding social behaviour, he holds, the acquisitive, sexual, gregarious and self-preservative instincts prove to be exceptionally powerful; and he argues that "much practical insight into normal and abnormal motivation is gained by regarding the various instincts and their accompanying emotions as the basic essentials of purposive action". But instinct is not all. Intelligence, as the psychologist defines the term, is equally an inborn factor. Differences in innate intelligence may limit the powers of self-control and of learning by experience. Hence individual intelligence has also to be taken into account in considering motive or lack of motive, and in proposing suitable treatment. In particular, as he points out, "it is characteristic of much anti-social behaviour that the desire of the moment, the proximate aim, is more importunate and decisive than a long-term ambition or desire".

Children and adolescents, owing to their immaturity, are largely under the sway of their innate impulses; and, particularly if brought up under adverse home conditions, may be slow in learning to control their conduct by intelligence or experience. Hence, during childhood and puberty, many forms of behaviour may arise as part of the normal development of the growing boy or girl which in an adult would be looked upon as criminal. In discussing the treatment of juvenile delinquents, Dr. East briefly notes the valuable part that may be played by child guidance clinics both in prevention and cure; and is apparently inclined to attribute much of the delinquency that is rife among children at the present day to ignorance of "even elementary standards of conduct". As to the means of combating this ignorance, he cites the view of the Middlesex Education Committee, which urged that "religious education was the surest means of acquiring these standards", and reported that teachers themselves were showing "considerable enthusiasm for this branch of education".

Since criminality is more apt to arise in persons of abnormal mentality, Dr. East, like most medical investigators, has paid special attention to the association of anti-social behaviour with insanity, with mental deficiency, with neuroses, and with psychopathic states; and quotes authoritative figures. "Although no particular crime is characteristic of insanity, the proportion of homicides in this country who are insane is much greater than the proportion of those who commit other offences"; but "criminal conduct associated with insanity may extend almost throughout the whole gamut of crime". The forms of major mental disorder chiefly associated with crime are schizophrenia, manic-depressive disease, and paranoid states; and since in each of these conditions inheritance appears to play an appreciable part, eugenic marriages, he argues, may tend in some degree to diminish the number of offspring liable to develop anti-social behaviour. However, as he goes on to point out, the frequency of definite insanity among criminals is exceedingly small: the number of persons received into prison who are either insane on reception or become insane during detention is barely 1 per cent of the admissions.

Mentally defective criminals are even fewer; they form only half of 1 per cent of the admissions. However, the higher grades of mental deficiency shade off imperceptibly into normality through a subnormal group, who may also display anti-social behaviour. The mentally deficient "commit various crimes including murder at one end of the scale and vagrancy at the other"; but "the majority of their offences are connected with the acquisitive instinct, namely, theft, embezzlement, false pretences and the like; next in frequency are various sexual offences; but, as with insanity, no particular kind of crime is characteristic of the condition". The defective offender, however, very easily forms a criminal habit; and the danger to the community from his misconduct is to be measured, not merely by a particular offence, but by his incorrigibility. Hence the importance in these cases of enforcing early institutional care. A large measure of prevention has already been secured by prompt ascertainment, followed by segregation or supervision; but, it is argued, if eugenic principles could be applied, still more anti-social behaviour would be prevented.

Since psychoneurosis is often precipitated by emotional maladjustment, it is not surprising to find that many criminals show neurotic symptoms. Here precise figures are harder to obtain. Hysteria, Dr. East believes, is far more frequently associated with major forms of anti-social behaviour than is sometimes supposed. Anxiety states, too, may often form the chief cause. On the other hand, contrary to notions prevalent among the general public, obsessive and compulsive states are not often related to serious misconduct; and, apart from the occasional effects of the accompanying hypersensitiveness and irritability, neurasthenia (in the proper sense of the term) is comparatively infrequent as a causative factor. In his investigation of 4,000 adolescent criminals, Dr. East found no more than 48 suffering from definite psychoneurosis—not much more than 1 per cent. In all such cases Dr. East once again stresses the importance of early recognition: the more promptly psychotherapeutic measures are applied, the less likely is anti-social conduct to ensue.

In criminological literature the phrase 'psychopathic personality' often becomes (as Dr. East acknowledges) a kind of waste-paper basket, into which anything that cannot be pigeon-holed under more definite headings may all too easily be bundled together. Nevertheless, he believes that there is a small but well-defined group, including schizoid, cycloid and paranoid personalities, as well as perverts, drug addicts, alcoholists and the mentally unstable generally, to whom the term may be usefully applied. The disabilities and social difficulties of the so-called psychopath seem largely due to innate factors; and the prevention of anti-social disorders among such persons consequently presents a serious practical difficulty. Treatment has often to be restricted to efforts designed merely to modify the particular impulse or activity which is leading the patient into conflict with the law.

On the whole, however, as Dr. East insists, "the majority of prisoners found guilty of criminal offences do not show abnormal characteristics (although, of course, they exhibit individual variations among themselves, just as other groups of persons do). . . . The figures disprove the assertion of those who declare that crime is a disease." Coming from one who, in virtue of his work, his experience, and his writings, is among the foremost authorities on the subject in Great Britain, and is himself a medical man, this is a most significant pronouncement. Both in the medical and in the educational world there are still numerous writers and administrators who do not realize how opinion upon this point has changed. The trouble seems to be that laymen and Government officials are alike inclined to think that the qualified expert in mental science must be the medical man. Psychology, owing doubtless to the publicity given to its more sensational problems, is confused with psychoanalysis, and not yet regarded as a science in its own right. Many of the pioneers who have urged that the prime need of the adult criminal is treatment rather than punishment have done so on entirely misleading grounds, namely, that "crime is a pathological symptom, and therefore the criminal should be accorded the same medical care as any other mental sufferer". Similarly, when child guidance centres were established they were called 'clinics' (as though backward pupils as well as young delinquents were mentally diseased); and it has been the official policy of the Child Guidance Council itself that "since crime is a form of illness, the child guidance clinics at which such cases are examined should be under a medical director". No doubt, in a small proportion of the cases, moral delinquency, like educational backwardness, may be the outcome of physical or mental illness; and in every case the first step is unquestionably to investigate the possibility of such illness as a contributory factor. Recent investigations, however, like those of Dr. East, prove conclusively that it is, as a rule, only a minor factor, and a comparatively rare one at that. Hence, as recent experience has shown, there is considerable danger that exclusive or excessive emphasis on the need for a medical approach may lead to the neglect of other lines of study and treatment that are far more important—the social, the educational, or the psychological.

In all cases of delinquency or crime it is the psychological rather than the physical or pathological characteristics of the individual that call for first consideration. But in early years it is the social and educational environment—the home and the school—that are usually the deciding factors. "The home," says Dr. East, "should be the first training ground." The lad who comes from a broken home or from a family where discipline is unduly harsh, unduly lax, or so erratic as to be virtually non-existent, is not only more liable to drift into vice and crime, but also more resistive to subsequent efforts at reform. A wholesome training in the school is equally essential as a supplement to, and often as the only substitute for, the training in the home. "But its value is not to be measured by its success in teaching a lad how to acquire knowledge or even by its material usefulness in after life : . . . the formation of moral principles and habits is the most important part of education." "For this and other reasons," Dr. East observes, "the criminologist will welcome the proposal to raise the school-leaving age." As regards economic conditions, he finds that the relative amount of unemployment among offenders was not appreciably greater than that obtaining among the general population: but they seemed far more liable to commit their offences during spells of unemployment than at other times. In particular, he urges the importance of vocational guidance as a means of combating delinquency: among adolescents more especially, it would seem. "wrong placements tend to invite anti-social behaviour".

As to punishment, Dr. East notes that "the tradition that imprisonment is solely punitive still persists in certain quarters; but it cannot be too widely known that its modern purpose is treatment and training". This, as he points out, is the attitude taken in the Criminal Justice Bill of 1938, which was before Parliament before the outbreak of the War. That penal measures do not altogether fail is, in his view, borne out by after records: thus "of 17,918 males and 2,749 females who were over the age of 16 years in 1932, and were found guilty in that year of offences sufficiently serious to warrant the taking of finger-prints, and had no previous proved offences recorded against them, 90 per cent of the older males, and over 70 per cent of the younger, were free from any further charges during the subsequent five years : the figures for females were nearly 90 per cent".

Due attention to the psychological study of the criminal must be one of the items that should claim a foremost place in the programme for post-war reconstruction. Since at the moment the urgent need is knowledge, more detailed, more precise, and, in a word, more scientific, about the reactions of the individual mind, one of the first steps should be to establish "an institution where research into the problems of criminal behaviour, and the scientific treatment of offenders, can be carried out". "And the conclusion of the whole matter," says Dr. East, "seems to lie in the fact that a democratic State can no longer afford to ignore the effects of social hazards which are harmful and preventable; the treatment of delinquent and criminal behaviour are not merely matters that concern lawyers, administrators and scientists; they are matters that concern us all."

A PHYSIOLOGICAL THEORY OF COLOUR PERCEPTION

By Prof. RAGNAR GRANIT

Neurophysiological Laboratory, Karolinska Institutet, Stockholm

It is nowadays possible to record the discharge of the retinal elements directly by leading off to electrodes from more or less isolated fibres of the optic nerve. The electrical impulses following upon illumination are the physiological means of communication between the retina and the higher centres. They are amplified and led to an oscillograph for photographic recording and at the same time listened to in a loud-speaker. This is the technique for which the well-known work of Prof. E. D. Adrian and his collaborators originally laid a solid basis. For isolation of the fibres in the optic nerve a method of micro-dissection around the blind spot has been developed by Hartline[1] and a micro-electrode technique for picking up from the fibres inside the eye by Granit and Svaetichin[2]. The latter method is a great deal simpler and faster than the former, and for this reason it is the natural instrument for a rapid survey of the colour properties of a large number of single or grouped units in the response of the eye to illumination with spectral light of known energy

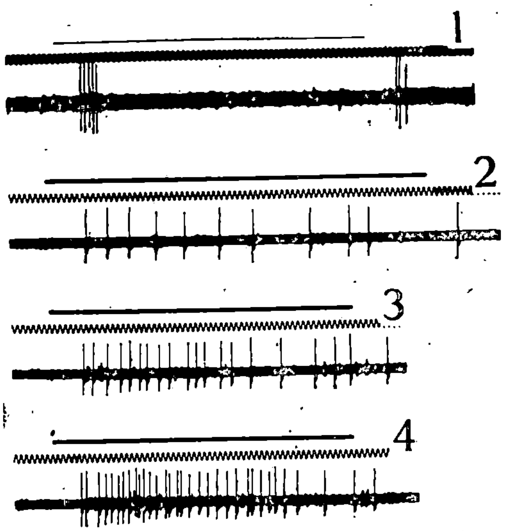

Fig. 1. IMPULSES PICKED UP BY A MICRO-ELECTRODE PLACED ON THE NERVE FIBRES INSIDE THE RETINA. ABOVE EACH OSCILLOGRAM IS THE TIME RECORD (50 PER SEC.) AND LIGHT SIGNAL.

1. "On-off"-element from photopic cat's retina responding to light of wave-length 0·660 μ. Somewhat above threshold.

2–4. "On"-element from scotopic retina of guinea pig responding to "white" light: 2, at strength 0·006 m.c.; 3, at 0·018 m.c.; and 4, at 0·061 m.c. Note increasing frequency and shortening latent period, as stimulus intensity increases.

content. Mammalian eyes can be studied with the micro-electrode as easily as eyes of the cold-blooded animals, to which the technique of micro-dissection is limited if it is to be used for analytical purposes. The animal is anæsthetized, cornea and lens removed, and the micro-electrode inserted with the aid of a micro-manipulator under suitable optical magnification.

Successful isolation, in mammals particularly easy to accomplish, leads to a discharge of spikes of impulses (Fig. 1). In different elements a response follows onset of illumination or both onset and cessation of illumination, as first noted by Hartline[1] with the frog's eye. In the latter and in some other eyes, there are also elements which merely respond to cessation of illumination. But these different types of responses are of less interest in this connexion because of the absence of any definite correlation between type of discharge and type of colour sensitivity, to judge by the work so far carried out.

In order to analyse the colour sensitivity of such discharges, we proceed to measure the amount of energy necessary for eliciting a threshold response in the different wave-lengths of the spectrum. If the element under the electrode has low sensitivity for light of a given wave-length, much energy is needed to elicit a discharge; if it has high sensitivity, little energy is required. Thus the inverse value of the energy necessary for a threshold response in each wave-length is the ordinate (per cent of the maximum) plotted in the curves of Figs. 2 and 3, illustrating the spectral properties of the retinal receptors. I shall briefly direct attention to some results of general interest from work published during 1940–42 (*Acta Physiologica Scandinavica*; preliminary review, *J. Amer. Opt. Soc.*, **31**, 570 (1941)). Since then the number of animals studied has been extended and principles have emerged which in my opinion suggest a relatively simple interpretation of some of the fundamental facts of colour vision, particularly of the differentiation of our sensations into the two categories of brightness (or luminosity) and colour. The principles discovered may also be of practical importance.

Analytically, the simpler structure is the dark-adapted eye with its rods fully charged with visual purple. We are familiar with the absorption curve of this substance. It was first accurately determined, with in every respect satisfactory and up-to-date technique, by the late R. J. Lythgoe[3], of University College, London. Our electro-physiological analysis of eyes of different animals in dark-adaptation has shown that a plot of the inverse value of the energy necessary for a threshold response reproduces the absorption curve for visual purple with perfect fidelity, provided that the curves are corrected for presentation in terms of quantum intensity, a necessity first pointed out by Dartnall and Goodeve[4] in NATURE. The maximum of this absorption curve is around 0·500 μ. Visual purple also determines the luminosity curve of the dark-adapted human eye (scotopic spectrum). After the latter has been light-adapted the maximum of our luminosity curve shifts to the region of 0·560 μ (Purkinje shift) and the new curve obtained determines the distribution of brightness in a spectrum strong enough to elicit sensations of colour (photopic spectrum). As is well known, the retina is then supposed to utilize cones as receptor elements.

In light-adapted eyes of animals the simple spectral sensitivity curves recorded with the micro-electrode technique are of two types: (i) broad absorption bands, here called *dominators*; and (ii) narrow bands, here called *modulators*. The most interesting fact about the photopic dominator, apart from the width of the curve, is the localization of its maximum to the region around 0·560 μ, as shown in Fig. 2 for frog and snake (Tropidonotus); the latter a pure cone eye which need not be light-adapted to give this curve. The same dominator has been found in the eye of the cat. The dominator is lacking in the eyes of guinea pigs and rats. The form and spectral locus of the dominator is practically identical with the average curve obtained from massed receptors in the light-adapted eyes of the same species. In this sense the dominator may be called the carrier of the Purkinje shift. This and its good correspondence with respect to form and locus with the luminosity curve of the light-adapted human eye necessitate the conclusion that the dominator is responsible for

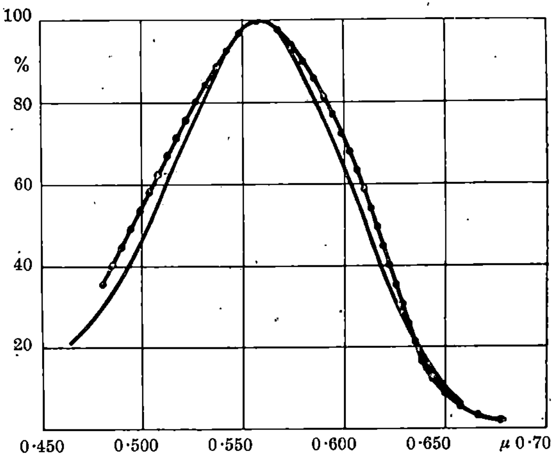

Fig. 2. DISTRIBUTION OF SENSITIVITY OF "DOMINATOR" ELEMENT IN THE RETINA OF FROG (UNINTERRUPTED LINE) AND SNAKE (LINE INTERRUPTED BY DOTS).

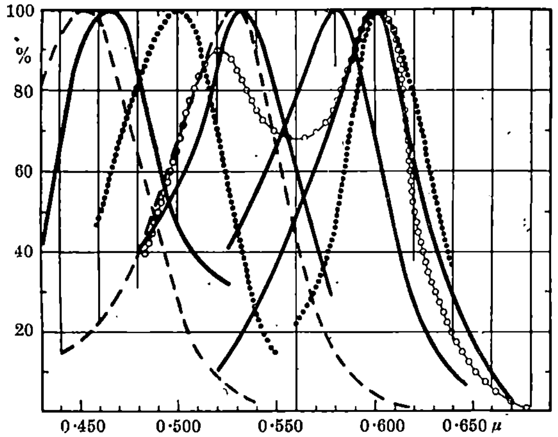

Fig. 3. DISTRIBUTION OF SENSITIVITY OF "MODULATOR" ELEMENTS FROM EYES OF RAT (DOTS), GUINEA PIG (BROKEN LINE), FROG (LINE IN FULL) AND SNAKE (LINE INTERRUPTED BY CIRCLES). NOTE THAT ALL CURVES ARE IN PERCENTAGE OF THE MAXIMUM AND THAT A NUMBER OF ORDINATES ON EITHER SIDE OF 0·560 μ ARE DRAWN DOWN TO INDICATE "DOMINATOR" VALUES. ALL SPECTRA OF EQUAL QUANTUM INTENSITY IN BOTH FIG. 2 AND FIG. 3.

the sensation of brightness, which thus is our dominant impression, coming, as it does, from the dominant receptor, dominant also in the sense that it is the most frequent one.

How then is colour vision possible ? Modulation of the dominant impression of brightness to colour would seem to be the task of the much rarer modulators which occupy very narrow bands of sensitivity in three preferential regions around 0·580–0·600 μ, 0·520–0·540 μ and 0·450–0·470 μ. These are shown in Fig. 3. In addition, there is also in some eyes (rat, guinea pig) a narrow band in the region of 0·500 μ, which is the spectral locus of the maximum of the absorption curve for visual purple. The rat has 1 per cent cones, the guinea pig still less, if any. It is an interesting fact that in these eyes, which lack dominator and Purkinje shift, light-adaptation does not completely remove the absorption curve for visual purple but changes it to a very much narrower curve of modulator type, still placed in the same region. Light-adapted rods in this case serve as cones.

The most regularly recurring modulator in the different species studied has been the 'red' one with maximum at 0·600 μ. It has even been found in the eye of the rat, which lacks the dominator, but not in guinea pigs. In the cone eye of the snake the 'red' modulator was generally, though not always, connected to a 'green' hump at 0·520 μ, which sometimes was more, sometimes less, developed. Its narrowness (see Fig. 3) suggested a 'green' modulator which, however, was never obtained in the isolated state in this animal. But in guinea pigs and frogs 'green' modulators with maxima around 0·530 μ were seen. The 'blue' modulator was first found in the eye of the frog, then in the guinea pig. In both retinæ it is quite common in the shape of a hump on other curves, but it is difficult to isolate. The frog, of all the animals studied, has the most complete set of modulators (cf. Fig. 3). As rods and cones may converge towards a common retinal ganglion cell (Polyak[5]), and as many other factors antagonize isolation, it is clear that all attempts to interpret complex curves as well as to understand the nature of the sensory message as a whole must begin by emphasizing the positive character of the evidence for the existence of curves as simple as the modulators. Complex curves with several humps are, of course, common.

The experiments with the cone-eye of the snake suggested that the dominator itself is composed of modulators joined together in such a fashion—either photochemically or by connexions in the retinal synapses—as to operate as a *functional unit.* However, this assumption, though probable, is not essential to the theory based on the experiments. But it would explain why stimulation of all modulators together also causes an impression of white, and not of all colours confused. The modulators would in this case merely add to the effect of the dominator. Alternatively, the modulators could be coupled in antagonistic pairs which simultaneously neutralized each other at the retinal or some higher level. As a matter of fact, in eyes where both 'red' and 'green' modulators are present, they are very difficult to isolate from each other.

But let us now see what kind of theory of colour vision would be a direct consequence of the experimental subdivision of the receptors into a great number of almost identical dominators and a smaller number of narrow modulators varying somewhat in shape, locus, sensitivity and number within three preferential spectral regions. No further assumptions will be introduced beyond the original one, that the dominator stands for the dominant impression of brightness, and is modulated by the modulators so as to give the higher centres a cue for their integration of 'colour'.

(1) The greater the distance in the spectrum from the centre of the dominator the darker the colour. Colours towards the ends of the visible spectrum must be dark by comparison with those near the top of the dominator. This we know to be true.

(2) W. D. Wright[6] has shown that selective adaptation of the human eye to any colour causes chiefly a large general reduction of brightness and an insignificant selective effect on the fatiguing colour. This also is a direct consequence of a dominator for the perception of brightness. Classical theories would seem to require not only a much larger selective effect on the fatiguing colour but also a considerable shift of the luminosity curve.

(3) As it is improbable that all receptors would be of exactly the same threshold, a diminution of intensity should, on classical theories, lead to perception of coloured spots. Instead we know that it leads to the spectrum becoming colourless, with the brightness distribution of the dominator, as required by the presence of this most common receptor.

(4) Similarly, a reduction of area of the visual object, which is known to lead to disappearance of its colour with maintained brightness distribution, must do so because the 'small' stimulus merely has a chance of hitting upon the common dominators.

(5) Colour-blindness need not, but *can* be possible without parallel change of the photopic luminosity curve. A colour-blindness of this type would be the common form of red-green blindness known as deuteranopia, to be interpreted as absence of the 'red' and 'green' modulators, with the remaining dominator alone giving the normal luminosity curve. Without a separate structure for the perception of brightness as distinct from colour, no theory can ever hope to explain colour-blindness unaccompanied by considerable 'luminosity blindness' to light from the 'blind' region of the spectrum.

Many of the animals studied represent different types of colour-blindness if considered from the point of view of the complete colour sense of man. The guinea pig probably comes very near the totally colour-blind, the cat near the deuteranope. The cat has the typical dominator but no definite 'red' modulator. The guinea pig, however, has a number of different modulators in the short wave-lengths and hence may be able to discriminate colours in this region. But it lacks dominator and Purkinje shift. The totally colour-blind human has a photopic luminosity curve practically identical with the luminosity distribution of the normal dark-adapted eye dominated by visual purple. The guinea pig has the same scotopic *and* photopic sensitivity curve, slightly distorted by a hump in the blue in the photopic state.

With the three preferential regions for the modulators, it is clear that this theory can do what the trichromatic theory does and also that it demonstrates the essential correctness of Thomas Young's great generalization, although it is necessary to assume a greater or lesser number of somewhat different modulators within these regions. The main crux of the trichromatic theory and, indeed, of any classical theory, is the lack of precision in the concepts accounting for the perception of white as a separate entity which, nevertheless, somehow is intimately connected with the perception of colour. The trichromatic theory regards white as due to the summed effects of, chiefly, the 'red' and the 'green' sensitivity curves. This forces the theory to accept the consequence that removal of 'red' and/or 'green' should cause removal of the perception of luminosity in the same region of the spectrum. Hence there can be no colour-blindness without profound changes in the form and locus of the luminosity curve. It is an admission of failure to have to explain so important a phenomenon as deuteranopia by pushing it aside to be taken care of by the 'higher centres'.

Many of the phenomena to which the trichromatic theory has directed attention need not be discussed for the reason that my theory does not necessarily exclude the explanations already available. Thus, for example, the fineness of colour discrimination in different regions of the spectrum may be explained in the classical way, or else by the assumption that the number of slightly different modulators is particularly great in the regions where the maxima of colour discrimination are placed.

In its present form the theory gives no explanation of contrast colour, though certain alternatives seem reasonable in view of the fact that different elements are so often coupled together and that the retina contains a large number of coupling synapses. If a certain percentage of the 'red' and 'green' modulators are coupled together in such a manner that both are forced to discharge when either is stimulated, the natural result to expect from the asymmetry caused by fatiguing either of them is that the other one should predominate in the neighbouring region as well as in the off-effect. The experiments themselves have not yet dealt with situations calculated to bring forth contrast phenomena.

It is impossible in this brief review to deal with the available evidence concerning the nature of the colour-sensitive substances. The hypothesis I prefer is that visual purple—which may be called the dominator of the scotopic eye—is the mother substance for the photopic dominator and the modulators. Its molecule consists of a protein nucleus serving as carrier for about ten chromophoric groups (see Broda, Goodeve and Lythgoe[7]). The different colour sensitive substances may be due to changes in the linkage between carrier and chromophores.

DARWIN'S HEALTH

By SIR BUCKSTON BROWNE, F.R.C.S.

PERSONAL experiences of great men are always interesting, and often instructive. There has lately come to light a diary of his health by the immortal Charles Robert Darwin, from 1849 until 1854. It is now in the possession of the British Association for the Advancement of Science[1], and the Association's Secretary, Dr. O. J. R. Howarth, has permitted me to read it. It consists of thirty-four pages of unruled foolscap.

There is no doubt that the hardships of his five years voyage on board H.M.S. *Beagle* seriously affected Darwin's health. At first he tried to live in London, but found it impossible, and he sought a home in the country. He found it at Down House, Downe, Kent, sixteen miles from London, well away from any great road, quiet and secluded. He lived there for the rest of his life, forty years, dying in 1882, aged seventy-three. Down House is roomy, there are a large vegetable and fruit garden and considerable meadow land. It had no water or gas supply, and no bathroom. There was a cesspool—and a well. Cows and pigs were kept, the stables were large, and the dairy and coachman's house were separate buildings. There was a long path, called the "Sand-walk", along the northern side of the meadow land.

When Darwin began this daily account of his health, he had been married for ten years; he had a devoted wife, and a comfortable home, but the diary is a record of continual misery and suffering, although often the days are marked "good", and the good is sometimes underlined or even doubly underlined. His nights are disturbed by severe attacks of flatulence. In the daytime he suffers from attacks of sickness and vomiting. He has headaches and dizziness. He mentions lumbago and arthritis, and most painful of all, a succession of attacks of boils. They are allowed to burst of themselves and no antiseptics are used. One boil is described as "very large". He has pyorrhœa and sore gums and a tooth has to be extracted under chloroform. He complains that his writing has become very bad.

While the diary was kept, Darwin visited London, Eastbourne, and Great Malvern, where he tried the water-cure, and in a curtained corner of his study at Down House he kept a large shallow tin bath, and in the diary "douches" and "double douches" are mentioned. At the time a so-called electric belt was much advertised; it was tried and abandoned.

Darwin daily walked in his garden and up and down the "Sand-walk", and rode about the neighbourhood on a stout cob. After early manhood he smoked only occasionally. He became a regular snuff taker, but in order to keep the habit in abeyance kept his snuff jars in the hall, so that when desiring a pinch he had to rise and leave the room.

Darwin's last remaining son, Major Leonard Darwin, R.E., born in 1850, has given me the following particulars of his father's daily meals. He generally breakfasted alone; tea, with sugar, milk or cream, toast and a little bacon. He lunched with his family —joint, vegetables, and a simple sweet pudding. He drank a glass of sherry. He had afternoon tea with Mrs. Darwin. Dinner was a repetition of luncheon, and sherry was again taken. He never took ales or spirits, but often drank tea with his dinner.

Many have found the accounts of Darwin's continued ill-health somewhat mysterious. There cannot have been any organic disease, for he lived to be seventy-three, and all seems clear now—he was the victim of chronic indigestion, induced by five years of hardship at sea, with scant accommodation on a small ship and with roughly prepared food. All this would permanently upset the digestive organs of a highly sensitive man.

Indigestion results from: (1) imperfect mastication; (2) too much food; (3) improper foods. I think the cold baths must have done harm, and it is evident a good dentist should have been consulted, periodically. The stomach should have been called into action three, and not four, times daily. For many, afternoon tea is an insult to their luncheon and a menace to their dinner. I think his dietary was all wrong, but this is a professional matter not to be discussed in these pages. The sad thing is that there was so much suffering while "Malignant Fate sat by and smiled".

SCIENTIFIC CENTENARIES IN 1943

By ENG.-CAPT. EDGAR C. SMITH, O.B.E., R.N.

FOUR hundred years ago, on May 24, 1543, the famous astronomer Nicolaus Copernicus died in the city of Frauenberg, situated on the Fritsches Hof, about midway between Dantzig and Königsberg. He was buried in the cathedral, the centre of the diocese which he had served faithfully through his knowledge of canon law. As he lay on his bed stricken with paralysis, the first copy of his book "De Revolutionibus orbium cœlestrum, Libri VI" was placed in his hands, but it was too late; his memory had gone, his faculties were obscured. The book had lain completed for thirteen years, and it was only through the enthusiasm of the young German mathematician, Joachim Rheticus—whose attitude towards Copernicus was like that of Halley to Newton—that it was at last published. The expense of publishing was borne by Cardinal Schonberg, and to-day the first edition is exceedingly rare. A second edition appeared in 1566, and a third and last in 1617. Copernicus was just over seventy years of age, having been born at Thorn on January 19, 1473. Through his bishop-uncle he was able to study at Cracow, Bologna, Rome, Padua and Ferrara, at the last of which he took his doctor's degree in canon law. He returned north from Italy in 1505, lived at Heilsburg from 1507 until 1512, and from thence onward Frauenberg was his home. There is a statue of him at Thorn and another stands in the interior court of the library of the Jagellonian University, Cracow. A photograph of this was published in NATURE of March 2, 1922, to illustrate an article on "Science in Poland", and the question as to whether Copernicus was a Pole or a German was the subject of remarks in these columns so long ago as December 21, 1871 (p. 151).

A century after Copernicus died, John Bainbridge, the first Savilian professor of astronomy at Oxford, passed away "at his house opposite Merton College in this his 62d year, and his body was conveyed to the public school, where an oration having been pronounced in honour of him by Mr. William Strode, the University Orator, it was carried to Merton College Church and deposited on the left side of Mr. Henry Brigg's grave and an epitaph was inscribed upon his monument in Latin". Before his appointment to the Savilian chair, Bainbridge had taken degrees at Cambridge, kept a school, practised medicine and written on a comet. To what extent he had been influenced by the views of Copernicus we are not told, but his main interest was in Greek and Arabic scientific writings. A foreign mathematical contemporary of his was Habakkuk Guldinus (1577–1643), a Swiss Protestant who became a Jesuit and taught mathematics with success in the Jesuit colleges at Rome and Gratz.

Passing to the year 1743, we are faced with a long list of men of science, of greater or lesser fame, but all of interest. Of these the outstanding figure is Lavoisier, who was born in Paris on August 16, 1743, and fell beneath the guillotine on May 8, 1794. "The spring sends its green leaves and bright weather, bright May, brighter than ever: Death pauses not. Lavoisier, famed chemist shall die and not live: chemist Lavoisier was Farmer-General Lavoisier too, and all the Farmers-General are arrested; all, and shall give an account of their moneys and incomings, and die for 'putting water in the tobacco' they sold." So wrote Carlyle. Twenty-eight Farmers-General and their three assistants were sentenced at one sitting of the Tribunal of the Terror; and it was then that the terrible Coffinhal immortalized himself by replying to Lavoisier: "The Republic requires neither savants nor chemists; the course of justice cannot be suspended". Condorcet (1743–94), author of works on the calculus, and of "The Progress of the Human Mind", perpetual secretary to the Royal Academy of Sciences, only escaped a similar fate by taking poison, but the unfortunate German astronomer, Johan Wilhelm Wallot (1743–94), who had been employed on the testing of Leroy's chronometers and had lectured and observed in Paris for many years, perished on the scaffold on July 27, the day before Robespierre fell and the prisons were thrown open. The 'father' of crystallography, René Just Haüy (1743–1822), born six months before Lavoisier, was at one time in danger, but friends came to his rescue. None took a more active part in the foundation of the metric system than Lavoisier, and in some of his measurements Haüy was associated with him. There is a statue of Condorcet near the French Institute, and statues of Lavoisier behind the Madeleine Church and at the Sorbonne. A reduced replica of the latter is in the National Gallery of Scotland.

The discoveries and theories of Lavoisier were embraced by some chemists and rejected by others, but the credit for their favourable reception in Germany was largely due to the tireless Martin Heinrich Klaproth, who was born on December 1, 1743, and died on January 1, 1817. Klaproth made a host of accurate analyses of minerals and discovered several elements. In 1792, when professor of chemistry in Berlin, he proposed to the Berlin Academy of Sciences to repeat the more important of Lavoisier's experiments. His offer was accepted, and from that time most of the Berlin chemists declared in favour of the new theories. With F. B. Wolff, Klaproth published the first German chemical dictionary. Another French chemist of this time was Antoine-Alexis-François Cadet-de-Vaux, born in Paris on September 13, 1743, whose investigations dealt with matters of domestic economy, public health and agriculture.

In other fields of science occur the names of Antonio Cagnoli (1743–1816), the intimate of Lalande, who had observatories in the Rue Richelieu in Paris and at his birthplace, Verona; of Johan Ferber (1743–90), a learned Swedish mineralogist and traveller; of Colonel James Capper (1743–1825), of the East India Company, who in 1801 published his work on winds and monsoons, and of the two self-taught British mathematicians, John Mole (1743–1827), originally a farm labourer, and Henry Andrews (1743–1820), first a domestic servant and then a bookseller. For forty years Andrews calculated for the "Nautical Almanac", and as the compiler of "Moore's Almanac" raised its sale from 100,000 to 500,000, getting but £25 a year from the not too generous Stationers' Company. Among the other publications of the Stationers' Company was the "Ladies' Diary", begun by John Tipper in 1704. When Tipper died in 1713, Henry Beighton became its editor, and conducted it successfully until his own death in 1743. The "Ladies' Diary" filled a place in the mathematical life of Great Britain in the eighteenth century, and Beighton in his prefaces speaks of it as being "peculiarly adapted for the use and diversion of the fair sex", and of his own "gallant endeavours to introduce his readers to the study of the mathematical sciences". Beighton too has a place in the history of experimental science and of the steam engine.

To complete the review of the bicentenaries which fall this year, mention may be made of the ingenious Rev. Edmund Cartwright (1743–1823), the inventor of the power loom, over which, and other inventions, he lost a sum of £30,000; a Government grant in 1809 of £10,000 made the evening of his life comfortable, and he was afterwards remembered as "a portly dignified old gentleman, grave and polite, but full of humour and spirit".

If for no other reason, the centenaries of men of science who died in 1843 would be of interest inasmuch as they include that of the French astronomer, Jean Nicolas Nicollet (1786–1843), whose intelligence and spriteliness as a boy were maintained throughout his life and led him to have a share in the greatest scientific deception ever perpetrated—the so-called "Moon Hoax". Born to a life of poverty and drudgery, from these Nicollet was rescued by the local curé, and he ultimately gained an education which led him to the librarianship and secretaryship of the Paris Observatory. Grant refers to a "beautiful paper" of Nicollet's in the "Connaissance des Temps", 1822, and to observations he made with Bouvard on the moon's libration in longitude. But it is not for such things he will be remembered longest. Desiring to be rich, he speculated on the Stock Exchange, lost, got into debt and then fled to the United States. That was in 1831. In 1833, Sir John Herschel, with considerable public attention, sailed to the Cape to survey the southern heavens. An unforeseen result was the compilation of accounts of most extraordinary discoveries he had made in the moon. Sir John, of course, knew nothing of them. The ball was apparently set rolling by the Somerset-Cambridge man, Richard Adam Locke, as impecunious as he was versatile and unscrupulous. In 1832, at the age of thirty-two, he too went to the United States, where in 1833 the New York *Sun* made its first appearance. To the editor of the *Sun* Locke proposed an account of Herschel's discoveries in the moon, and so in issue after issue one could read about brown quadrupeds, temples, man bats and what not. The *Sun's* circulation soared and Edgar Allan Poe declared Locke's hoax to be "the greatest hit in the way of sensation . . . ever made by any similar fiction either in America or Europe". At any rate the story made people read, who had never read newspapers before. There is, however, another side to the matter. In Messrs. Sotheran's Catalogue, No. 826, p. 179, there is an entry: "The History of the Moon; or an account of . . . the Rocks, Trees, Flowers, Verdant Plains, Volcanoes, etc." (*c.* 1833), and the authorship of this is attributed by Messrs. Sotheran's to Nicollet, who "published the above account in the New York *Sun* partly to 'raise the wind' and partly to entrap M. Arago, his enemy, into believing it". Did Locke and Nicollet ever meet? Did they collaborate? What is the truth?

Of Alexis Bouvard (1767–1843), called by Miss Clerke "the indefatigable computating partner of Laplace", little seems to be known. He was perhaps the first to conceive the existence of a planet beyond Uranus. Another Frenchman of that time was Silvestre-François Lacroix (1765–1843), mathematical professor at the Collège de France and the Sorbonne. It was the translation by Herschel, Babbage and Peacock of his "Elementary Treatise on the Differential Calculus" which gave the first impulse to a mathematical revival in England. A Swiss mathematician of note who died in 1843 was Ferdinand Rudolph Hassler; Simon Newcomb married Hassler's grand-daughter. After taking part in the trigonometrical survey of Switzerland, Hassler went to the United States, in 1807 was made a professor at West Point Academy and in that same year put forward plans for a survey of the sea coast of the various States; thus he was the virtual founder of that great scientific service, the United States Coast Survey, of which he was the first director. He was born at Aarau in Switzerland in 1770.

Recrossing the Channel to recall some British men of science who died or were born in 1843, we come first to the well-known names of Macintosh, Hedley and Forsyth. Charles Macintosh (1766–1843), the industrial chemist, will always be remembered for his patent of 1823 for making waterproof fabrics by cementing two thicknesses together with india rubber dissolved in naphtha; William Hedley (1779–1843), one of the pioneers of the locomotive, will be remembered so long as his "Puffing Billy" stands in the Science Museum and his "Wylam Willy" stands in the halls of the Royal Scottish Museum, Edinburgh. The work of the Rev. Alexander John Forsyth (1769–1843) on the percussion lock for firearms is recorded on a memorial tablet erected on the walls of the Tower of London in 1930. To these names may be added that of Robert Bakewell (1768–1843), who when geology was first attracting widespread attention lectured up and down the country and wrote excellent text-books, the perusal of one of which awakened Lyell's interest in the subject.

When Herschel arrived at the Cape and set up his observatory at Feldhausen, the Royal Observatory near Cape Town had been nominally in existence since 1821, but no instruments were fixed until some years later. The Rev. Fearon Fallows was the first director and he was succeeded in turn by Thomas Henderson, Sir Thomas Maclear and Edward J. Stone, who in 1879 was followed by Sir David Gill. Gill was born at Aberdeen a century ago next June. Under Gill, who held the post of "Her Majesty's Astronomer" until 1906, the Observatory was completely transformed and it took a leading part in many of the principal projects of the day, including the great Astrographic Chart of the Heavens. Gill was also deeply interested in the measurement of an arc of meridian from the Cape northward through the entire African Continent. His retirement led to little lessening in his activities, and in 1913 he completed his "History and Description of the Cape Observatory". He died on January 24, 1914. Two other astronomers who laboured in the southern hemisphere in Gill's time were Henry Alfred Lenehan (1843–1908), the Government Astronomer of New South Wales and in 1905 president of the Royal Society of that colony, and John Macon Thome (1843–1908), who assisted and then succeeded Gould at the Argentine National Observatory at Cordoba.

Another eminent man of science holding, like Gill, a high official position and born in 1843 was Sir William Chandler Roberts-Austen (1843–1902), the successor of Thomas Graham at the Mint and the successor of Dr. Percy as professor of metallurgy at the Royal School of Mines, London. While assayer at the Mint, he was responsible for the standard fineness of about £190,000,000 of gold, silver and copper coin. He was the first secretary of the Physical Society, president of the Iron and Steel Institute and a Chevalier of the Legion of Honour. Some of his most valuable work was done for the Alloys Research Committee of the Institution of Mechanical Engineers.

To the foregoing may be added the names of Sir John Isaac Thornycroft, F.R.S. (1843–1928), the famous naval constructor and marine engineer; Ralph Hart Tweddell (1843–95), a pioneer of hydraulic tools for shipbuilding, bridge-building, etc.; George Frederick Deacon (1843–1909), a great water engineer who carried through the Vyrnwy Valley project in Montgomeryshire for the water supply of Liverpool; James Campbell Brown (1843–1910), for forty-three years associated with Liverpool as public analyst and as lecturer and professor of chemistry in the University; and finally the name of the eminent Belgian metallurgist, engineer and industrialist, Adolphe Greiner (1843–1915), director of the great Cockerill Works at Seraing, Bessemer medallist and president of the Iron and Steel Institute, who saw his medal and other valuables stolen during the "foul flood" which inundated Belgium a generation ago.

It will not have escaped notice that most of the men included in these notes were workers in the physical sciences. Readers who are more interested in the biological sciences can no doubt recall other workers of renown. One such distinguished man was the famous naturalist, Sir Joseph Banks, who, for forty-one years, was president of the Royal Society. Reference books differ as to the day and year of his birth, but Weld in his "History of the Royal Society" says he was born in Argyle Street, London, "on the 2nd of February, 1743 O.S.". Of the birth of the famous German bacteriologist, Robert Koch, who isolated the bacillus of tuberculosis, there is no such question. He was born at Klausthal in the Harz on December 11, 1843, and died in 1910; an obituary of him appeared in NATURE of June 2, 1910 (p. 402).

NEWS and VIEWS

Wooden Aircraft for War Purposes

IT has been announced that a wooden construction aircraft, the Curtis C.76 known as the Caravan, has just been completed in the United States, being the first of its kind, in that country, to be designed especially for war transport purposes. It is a high-wing monoplane, powered with two 1,200 h.p. engines. It carries two pilots and a radio operator, and has a large cabin space suitable for the carriage of troops, guns, or other military equipment. The body is built specially low when standing on the ground, and the doors are arranged to facilitate the quick transfer of the contents. Outlets specially suitable for paratroops are also provided. An interesting feature of this development is that it represents, with several British contemporaries the most notable of which is the Mosquito day bomber, a return from metal to wooden construction that has taken place since the outbreak of war.

The immediate pre-war policy of the Air Forces of most countries was to use metal construction (1) because it allowed a rapid expansion of output along mass-production lines, (2) because of its relative immunity from fire due to enemy bombing of large concentrations in store. War experience has almost completely reversed these. In the case of (1), the need for constant progress in design makes real mass production prohibitively wasteful in labour and materials allotted to production machinery, tools, etc. It also neglects a large reservoir of wood-working labour and machinery that has not so great a use in any other sphere of war production. With (2), the large concentration of war material close behind the static lines preparatory to an attack is no longer needed, partly because warfare has proved to be more fluid; also the speed at which it has been proved that aircraft can be concentrated at any given point allows it to be dispersed in store over a wider area. Another field for wooden aircraft is that of pure transport, distinct from fighting or bombing. The rapid carriage of troops or material to points where needed for fighting operations can proceed far enough away from the enemy to be reasonably safe from interference on a large scale, and the high speeds of the aircraft allow it to take evasive action to avoid isolated attack from occasional enemy machines. Thus a machine designed to a transport specification rather than a war one becomes the ideal, and in this case wood construction has many advantages.

Short-Wave Broadcasting: Transmission

SIR NOEL ASHBRIDGE, controller of the Engineering Division of the B.B.C., gave an account of "Short-Wave Broadcasting: Ten Years Technical Progress", in the Overseas Service of the Corporation on December 17. Sir Noel said that it is about eleven years since the B.B.C., in spite of inconclusive reports on the existing service, decided that an attempt should be made to build up a regular short-wave service to the countries of the British Empire, trusting to an improvement in both transmission and reception to make it justifiable. The bare principles on which the first station was designed did not differ in essentials from the much bigger stations which several countries are operating to-day. Wave-lengths in several groups within the limits of 13 to 50 metres are still used, except for the 100-metre transmissions to Canada, which are only used to overcome somewhat special conditions. Again, the principle of transmitting on directional beams, taking various parts of the world in turn, following the clock, still more or less applies to-day. No striking new invention has arisen to revolutionize the technique, but a great deal has been learned about the design of aerials, and how to construct them so that they radiate a beam of the right width and depth and as nearly as possible at the right angle to the earth, so that they will be reflected back to earth by the ionosphere, and arrive in that part of the world where they are intended to be received. The first experimental transmitter used only one wave-length, and the new station completed ten years ago used eight wave-lengths. We are now using no less than forty-four. The hours of transmission, too, are strikingly different; the first station with its two transmitters sent out twenty-three transmitter hours per day; but now the number of transmitter hours per day is more than three hundred and fifty-six. There was only one language used with the first station, as against nearly fifty at present.

Reception and Rediffusion

Big developments have also taken place at the receiving end. At the beginning, short-wave receivers were looked upon almost as scientific instruments which were of little use to people with no particular interest in technical matters. Even super-heterodyne receivers were comparatively rare only ten years ago, and undoubtedly it was the development of this type of receiver, with efficient automatic volume control and simplified tuning, which has done a great deal to convert a highly speculative undertaking into what may now fairly be called a firmly established institution. Another important factor has been the growth in the rediffusion of programmes by wires connecting a number of houses to a central receiving station. Such a station can be an elaborate and costly affair embodying the very best technique in short-wave reception. Such undertakings exist in many parts of the Empire, for example, Malta, and notably in the West African colonies. Somewhat similar advantages are gained by rebroadcasting through a local broadcasting station. The Empire and North American Services transmit for a total of nearly 149 hours a week, and are rebroadcast by wireless stations for nearly 55 hours, and when we include wireless exchanges this figure rises to more than 130 hours. Two pioneers who were instrumental in establishing wireless exchanges in several of the Colonies were Sir Arnold Hodson, recently governor of the Gold Coast, and Mr. F. Byron, an engineer in the Colonial Service.

The Future

All this development, both on the transmitting and receiving side, has taken place well inside ten years, and is not solely due to the War. What will be the future of short-wave broadcasting? Will people still go on listening and searching to see what they can find coming from distant countries? There is not much doubt that for some time they will, since news must be foremost in everybody's mind for many years to come. The question remains what will happen when and if news becomes a matter of less pressing importance to the whole world? Is short-wave broadcasting capable of further development, purely as a means of recreation and enjoyment? Whether the results obtainable by this means will ever be equalled by an ordinary direct listener in his home would at first sight seem doubtful, but if the progress in the next ten years is anything like that in the last ten years, we may look forward to the day when reception from far-off countries is almost as good as from the local station, and a few years after that we may even see the addition of pictures.

Nottingham Open Forum

An experiment successfully conducted in Nottingham during the last two months has aroused considerable local interest, and might well find favour in other towns and cities. The Nottingham Open Forum was sponsored by the British Council, in co-operation with University College, Nottingham, and the Ministry of Information, as an attempt to attain a better understanding and closer contact between local residents and visitors from overseas, both civilians and allied troops; and to stimulate informative discussion on matters of general interest. A series of meetings on 'Brains Trust' lines, but on a broad international basis, was arranged, and organizations such as the International Centre, the British Empire Club, the Polish Troops' Club, the Rotarians, Y.M.C.A. and Y.W.C.A., etc., were invited to co-operate, as well as the general public. It was felt that the public to-day prefers to be stimulated to think for itself rather than to be 'lectured at' and told what to think. The promoters of the Nottingham Open Forum have no political bias and are therefore free in their choice of subjects and speakers, and the members of each panel can express their views without reserve however controversial they happen to be. This type of meeting naturally has a much wider appeal than the usual 'public meeting' which is seldom free from the taint of propaganda. The information-seeking public is surely entitled to be at least as well catered for as the amusement-seeking public, and the successful presentation of any open forum or 'Brains Trust' depends largely on the care with which it is organized.

In Nottingham, "International Relations" was chosen for the first Open Forum; the audience was then invited to submit suggestions for future topics. This resulted in a wide variety of subjects from which the committee selected those of most general interest, including "Local Government", "The British Commonwealth", "Science and Modern Life", "Books, Writers and Readers", "Social Democracy", "Education: for whom and for what?", "Town and Country Planning", "National and International Law", etc. It is of obvious importance that the panel of speakers should be well-balanced and as representative as possible of the various aspects of each topic under discussion. For example, with "Local Government" as the subject, the panel consisted of a city councillor (Independent), the Deputy Town Clerk, an American city manager, a woman member of the City Council (Conservative), with a Labour M.P. (ex-chairman of the L.C.C.) as guest speaker. Much depends upon the question master, who introduces the speakers, and generally 'controls' his team. Questions are invited from the public, and an average number of about thirty are sent in for each meeting. It has been found that a good panel can deal with about ten questions in an hour, so the Committee gives careful consideration to selecting those questions which cover the most ground and provide the greatest variety. The audience particularly appreciates an opportunity of submitting written supplementary questions. Stewards (provided with pencils and paper) collect these during the session, and the last twenty minutes are devoted to dealing with them in a brisk 'sharp-shooting' fashion. One important feature of the Nottingham Open Forum is that the members of the panel meet for a few minutes before the public proceedings begin, when they are given a list of the questions. This avoids any confusion as to who shall answer each question first, and provides an opportunity for the speakers to decide when they can best make their own special contributions, while in no way destroying the spontaneity of their answers. The Open Forum has attracted an audience of from three hundred to four hundred at each meeting, and the enthusiasm shown has been gratifying. Especial appreciation has been expressed by foreign nationals from the occupied countries who are much impressed by the 'free speech' permissible in Great Britain. Further information can be obtained from the Secretary of the Nottingham Open Forum, Mrs. R. B. Calder, 5 Western Terrace, The Park, Nottingham.

Charles L. Mayer Awards for Animal Cell Growth Research

DR. WILLIAM J. ROBBINS, chairman of the National Science Fund of the U.S. National Academy of Sciences, has announced the creation of two 2,000 dollars prizes to be known as the Charles L. Mayer Awards and to be presented in 1942 and 1943 for outstanding contributions to our knowledge of factors affecting the growth of animal cells with particular reference to human cancer. The awards are to be not only in recognition of past accomplishments but are also designed to increase the opportunities of those with exceptional abilities to carry on further research. To assist the National Science Fund in effective administration of the Mayer Awards, a special advisory committee has been appointed consisting of Dr. R. R. Williams, chemical director of the Bell Telephone Laboratories, Dr. Alan Gregg, director for the Medical Sciences of the Rockefeller Foundation, Dr. George H. Whipple, dean of the School of Medicine and Dentistry of the University of Rochester, and Dr. Elihu Root, jun., as the lay member. The donor of the Charles L. Mayer Awards, Dr. Robins said, had in mind the vast possibilities offered by research on the action of chemical agents and physical factors in stimulating or retarding cell growth, and the National Science Fund would consider studies of factors controlling the growth of protozoa, of animal tissue cultures or of entire organisms as eligible.

In announcing the establishment of these Awards, Dr. Robbins directed attention to significant work which has been done on the amino-acids and some of the more recent discoveries on the importance of the rarer mineral elements, for example, manganese and copper, as necessary for animal cell development. Recent advances in the identification and isolation of some of the vitamins and hormones have opened new vistas for the student concerned with the control of growth. Along with the increased knowledge of factors stimulating growth there have been significant contributions to our information about growth-inhibitors such as the sulpha drugs and the anti-vitamins. Dr. Robbins emphasized that the Committee is interested primarily in fundamental studies on the factors influencing growth of animal cells rather than applications to any particular aspect of normal or abnormal growth. Applications based on such studies may develop in the future but at present we need more knowledge of the essentials concerned. Reports of empirical success in treatment of human cancer will not be eligible for the awards. The Advisory Committee will welcome suggestions at once as to outstanding published contributions and manuscripts of 1942 on any phase of this subject, at the National Science Fund offices, 515 Madison Avenue, New York City.

National Coal Board

AT the first meeting of the National Coal Board held on December 21, Major the Right Hon. Gwilym Lloyd George, Minister of Fuel and Power, presided. He pointed out that the establishment of the Board completes the final stage in the Government's plan for the war-time reorganization of the industry in Great Britain. The Board would advise the Minister, in whose hands control of the industry is vested, and he appealed to members of the Board to approach the problems with which they would deal from a national point of view, and on the basis of national service. Sub-committees were appointed for dealing with the following matters: (1) The general planning of production, including the allocation of district and regional targets. The best means of securing the highest efficiency of the coal-mining industry and any improvements in machinery or methods of operation whereby output may be increased. (2) The provision of supplies, equipment and materials for the conduct of mining operations. (3) Matters relating to the maintenance of man-power and labour productivity, including the enrolment of new entrants and the instruction, training and advancement of boys and youths. (4) All matters affecting the welfare of mine-workers, including housing, transport and feeding facilities; and questions of health and safety and, in particular, such occupational diseases as silicosis and nystagmus, with the view of providing all possible preventive measures, clinical treatment and rehabilitation.

The Turkish Earthquakes

EVER since the great Turkish earthquakes of December 27, 1939 (NATURE, **145**, 13; 1940), it has been noted that the earth-blocks in the affected district have never really attained their final position of rest. Aftershocks of the 1939 earthquake were frequent, of considerable amplitude and protracted. These followed the normal course, consisting of large shocks of gradually decreasing severity, interspersed with numerous minor shocks and tremors. Aftershocks, however, normally finish some months after their 'parent' shock and subsequent earthquakes with adjacent epicentres must be regarded as discrete. As recently as December last (NATURE, **150**, 687; 1942) renewed seismic activity in Anatolia was noted.

Ciorum appeared to have been the most affected during the preceding month, though Balikesir was also damaged. During this time about 20 people were killed, 24 injured, 1,600 houses totally wrecked and some further 1,300 partly wrecked.

The most recent very strong earthquake took place on December 21, 1942, and the epicentre appears to have been slightly to the east and very close to Erba. This place is approximately a hundred miles to the east of Ciorum, and west-north-west of the epicentre of the very severe 1939 (Erzinjan) earthquake. On the recent occasion Erba was almost completely destroyed, partly by the earthquake and partly by the fires which followed it, and it is feared that more than a thousand people have perished. Niksar, east of Erba, also suffered severely, as did the intervening villages. Erba is the centre of a rich tobacco-growing region about eighty miles south-east of Samsun on the Turkish Black Sea coast, and about 280 miles east of Istanbul. The strong shocks were also felt severely in Ordu, Sivas, Kastamuni, Bakir-chai, Tokat, Fatza, Kaisarieh and Zara, though no major damage is reported from the last-named place.

North African Natural History

As suggested earlier in the War, the armies in North Africa have stimulated much useful war-time observation of fauna and flora in otherwise difficult regions, and the current issue of *Countryside* (12, No. 5) contains original papers by members serving abroad. These include notes on the birds of the British list wintering in West Africa by A. C. Allnutt, who noticed that while whinchats wintered in the coastal region for the whole of the six winter months, the willow-warblers arrived in waves of migration and remained only a few days. Blue-headed and grey-headed wagtails were there from December until February but no nuptial songs were heard. Their feeding habits were no different from those observed in Europe. Waders seen regularly included the marsh-sandpiper, ringed plover, greenshank, bar-tailed godwit, black-winged stilt; those seen mainly on passage were the sandpiper, curlew-sandpiper, grey plover, redshank, spotted redshank, little stint, turnstone and sanderling. Migrating sandwich terns remained for several weeks, and the arctic skua and black tern were noted. Previous numbers of this volume of *Countryside* have contained notes on the birds of Tobruk. In the current issue Col. W. R. Roberts has notes on the flora of the Egyptian wadis near Cairo.

Fruit Growing

Allotments and gardens, though small units of horticultural production, are now so numerous that their aggregate contribution to the nation's nutrition is not small. The Ministry of Agriculture and Fisheries has recently issued "Growmore" Bulletin No. 7, "Fruit from the Garden" (H.M. Stationery Office, 3*d*. net, 1942) to assist the small grower to increase his production of fruit. Mr. J. M. S. Potter, of the Royal Horticultural Society, has written the text, which deals adequately with the planting and general management of stone fruits, apples and soft fruits. The bulletin's advice is eminently suited to the southern parts of Britain, but northern growers should not be advised to "avoid the strong growers like Bramley's Seedling and Newton Wonder". These varieties are often the most suitable for difficult climates. Many small apple orchards in the north are also unproductive because of the relative scarcity of other trees for pollination, and it is disappointing to find scant mention of suitable pollinating kinds for each variety. A useful spraying calendar is given, and sections on picking and storing, pruning, and the treatment of old trees also appear. Fruit culture is never so economically successful as when practised on a domestic scale, and it is good to see the Ministry's recognition of this important fact.

Planning of Science: in War and in Peace

The Association of Scientific Workers is organizing a conference to be held on January 30 and 31, at the Caxton Hall, London, S.W.1, on the planning of science in war and in peace. Sir Robert Watson-Watt, president of the Association, will open the Conference. The first session will deal with the central direction of scientific research and development, and Sir Stafford Cripps has agreed to speak. It is also hoped to have statements on the organization of science in the U.S.A. and the U.S.S.R. The second session will be devoted to the local organization of scientific research and its application; among the speakers will be Mr. W. C. Devereux, managing director of High Duty Alloys, and Mr. Ben Smith, national organizer of the Association, who will speak on the relationship between managements and scientific staff as it affects production; detailed consideration will be given to the relations between scientific and other workers and to the work of joint production committees. The third session will discuss those changes in the organization of science brought about during the War which may have a continuing effect on the relations of science with society, and the re-orientation of science after the War. Prof. P. M. S. Blackett and Sir Lawrence Bragg will be the main speakers. The chair will be taken by Prof. J. D. Bernal. Tickets (2*s*. 6*d*. for whole conference or 1*s*. per session at the door) and full particulars can be obtained from the Conference Secretary, Association of Scientific Workers, 73 High Holborn, London, W.C.1.

Announcements

No. 3 of the War Background Studies issued by the Smithsonian Institution is by Dr. Aleš Hrdlička and is devoted to an account of the peoples of the Soviet Union. While there is nothing in these twenty-nine pages which purports to be new matter, the little publication gives a very convenient conspectus of the early history and make-up of the peoples of the U.S.S.R. It is compiled for the general public.

The following appointments and promotions in the Colonial Service have recently been made: J. F. A. Sprent, veterinary research officer, Nigeria; I. H. Pattison, veterinary officer, Palestine; J. R. Curry (agricultural officer, Tanganyika Territory), director of agriculture, Bahamas; M. Greenwood (specialist (chemistry), Agricultural Department, Gold Coast), senior specialist, Agricultural Department, Gold Coast.

The Institution of Naval Architects is offering two scholarships in naval architecture (Elgar Scholarship, £130 a year, and Denny Scholarship, £100 a year) and two in marine engineering (Parsons Scholarship, £150 a year, and Yarrow Scholarship, £100 a year) for competition in 1943. The age limit for the Denny Scholarship is nineteen, and that for the other scholarships twenty-three. Particulars can be obtained from the secretary of the Institution, 10 Upper Belgrave Street, London, S.W.1.

LETTERS TO THE EDITORS

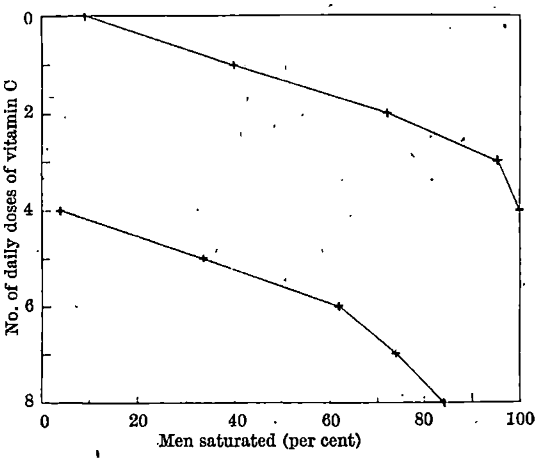
Vitamin C Saturation Test of Harris and Abbasy

DURING a year's service in the R.A.M.C., six months were occupied exclusively in carrying out and reporting upon this test[1] according to a scheme drawn up by the Directorate. Though the results concerning the 1,200 men examined cannot be given, some remarks on the method appear to be worth recording as based on experience gained in performing some thousands of titrations; also a couple of points accidentally discovered may be mentioned.

Much time is saved by having the fourth and fifth hours, after dosing with ¾ gm. of the vitamin, as the period of retention of urine and by making up the sample to ½ or one litre, instead of having the often inconveniently long three-hour period and measuring the volume of each sample. The 2 : 6 dichloro-phenol indophenol reagent is best adjusted so that 1·0 ml. corresponds to 0·1 mgm. of vitamin. By these small alterations several weeks of simple arithmetic were eliminated in the second tour.



The method was found to give consistent results capable of distinguishing between groups of 100 men living under slightly different conditions of vitamin C intake. These differences are clearly shown when one plots on the vertical axis the number of daily doses required to approach saturation, namely, an excretion of 35 mgm. of vitamin in a two-hour period, and on the horizontal the total percentage of men who have reacted before and on that day. The forms of the curves are shown in the accompanying figure, in which the upper relates to a population extremely well supplied with vitamin C and the lower to a badly fed one, in which those with the lowest reserves are approaching frank scurvy; cases of scurvy require about ten doses to become saturated, and no information is given about the 16 cases below the 8-dose limit. These curves do not represent conditions in the Army. Their importance lies in the fact that they show an appreciable personal variation existing in a population on a fairly uniform diet, and make it clear why some, and not all, of a ship's company become affected with scurvy. Severe muscular exercise is known to produce scurvy in those low in reserves of vitamin C, so possibly some men use up more than others, or minor differences in tastes or in cooking may be responsible.

There remains the question of the individual assimilation of the vitamin ingested. This may be very unequal. Information on this point was obtained through an accident. Two sections of men belonging to the same unit and feeding from the same cookhouse responded very differently to the doses, for one showed its peak of saturation about two days earlier than the other. The numbers, 22 and 21 respectively, appeared to rule out a chance aggregation. This remained a puzzle until on returning to the station four months later it was ascertained that a visiting unit was dosed after the first section, and that the second home section had breakfast before being dosed. Apparently the vitamin suffers less destruction when taken after food. A direct experiment should be made to test this accidental finding.

Additional evidence was obtained that this vitamin, unlike vitamin D, is not stored in quantity for long. For it was found that those dosed at one station in May included about 40 per cent dosed four months previously. When three lists were prepared (*a*) those saturated in January, (*b*) all those previously dosed, (*c*) those not dosed before, three curves were obtained, roughly parallel, with *a* uppermost, then *b* and *c*, but only about ¾ of a dose separated *a* from *c*. Thus there were men in class *c* with much higher reserves than in *a*, though after *a* had been saturated all lived on the same diet.

Vitamin C Saturation Test: Standardization Measurements at Graded Levels of Intake

DR. ATKINS's valuable account of his experiences with the saturation test prompts me to send a brief summary of my own unpublished observations bearing on two of the points to which he alludes: first, the degree of 'scatter' in the responses seen in different subjects kept on the same or similar intakes; secondly, the choice of criteria to be used.

In my own tests, groups of boys (12–36 in each group) at a residential home were kept on a basal diet of known vitamin C content and given in addition various graded supplements of vitamin C, natural and synthetic, over periods of 3–4 months or longer, so that each boy in a group received identically the same intake. About twice a year (an interval found to be sufficiently long to allow the effect upon their 'reserves' of any previous saturation test to have become negligible), the boys were tested by the standardized procedure previously described[1], 700 mgm. per 10 stone being given daily and the number of days counted until the approach of saturation (taken as an excretion of 50 mgm. or more per 10 stone in the 2¼-hour specimen collected in the fourth and fifth hours after each test dose).

Results were found to be graded, as follows: daily intakes of 75, 60, 50 and 45 mgm. gave first-day responses of decreasing magnitude; 40 mgm., first to

R 281

second-day responses; 25 mgm., second to third-day responses, the 'scatter' in the responses of subjects kept on the same level of intake being small (see table). In earlier tests, children on still lower intakes had third-day to fifth-day responses. Similar graded results have been recorded with adults on varied intakes, patients with scurvy taking 7–10 days to saturate.

Date	Daily intake of vitamin C (mgm.)	Total number of boys in group tested	No. of boys approaching saturation			
			1st day	2nd day	3rd day	4th day
Autumn 1941	75	12	12	0	0	0
	60	10	10	0	0	0
	45	10	9	1	0	0
Spring 1942	50	12	12	0	0	0
	40	11	5	6	0	0
	25	12	0	5	7	0

As a standard of reference in assessing results of surveys, it is noted that an intake corresponding with the League of Nations requirement (30 mgm.), or an amount not greatly in excess of it, suffices in nearly all subjects to give responses on the first or second day of dosing. The number of days beyond the second may be taken as an index of the relative deficit in the past intake. For high and low base lines respectively, it is observed that with intakes of the order of 50–75 mgm. per day (the optimal standard recommended by some American authorities), saturation is attained on the first day of dosing, whereas with intakes appreciably below the League of Nations standard three days and upward are needed, reaching a limit of seven to ten days for cases of developed scurvy. These criteria agree with those previously suggested[1].

It is hoped to publish the extended data elsewhere.

Vitamin C Intakes at a Residential Home

Since July 1941 we have been making a study[1] of the vitamin C in the diet at a residential institution (home for waifs and strays at Cambridge), in order to obtain information about the day-to-day intakes, the influence of seasonal fluctuations in the supply of available sources, the effect of the War, etc. Chemical analyses were made on representative specimens of the various cooked and raw foods served and the results used to calculate each day's total intake. From time to time complete meals were analysed as a further check on the calculated values, and the agreement was good (average 'predicted' result was 110 per cent of average 'determined' result).

The average daily intakes (in mgm.) were as follows: 1941: July, 23; August, 35; September, 55; . . . 1942: January, 24; February, 27; March, 19; April, 19; May, 23; June, 24; July, 42; August, 53; September, 53; October, 38; November, 35. The pronounced difference between the intakes in summer and winter was reflected in the results of saturation tests (first-day response in all instances after summer, as compared with second to third-day response in all instances after winter).

The change from old to new potatoes in late July (1942) or late August (1941) made an addition of about 30 mgm. per day. The other notable cause of the higher values in the summer was the increased use of garden produce, for example, cabbage, cauliflower, spinach and some fruits.

Apart from potatoes, important because of their regular use and the relatively large amounts consumed, the principal source of vitamin C throughout the year was provided by the green vegetables, such as cabbages and sprouts. Cooked vegetables had an advantage over raw in that much larger quantities could be eaten and assimilated. The water in which the vegetables had been cooked was utilized for preparing gravies, etc., and also furnished an important supply of vitamin C.

In this institution dietary practice was particularly good, with the result that the vitamin C intakes and levels of nutrition, as determined by saturation tests[2], were considerably higher than average working-class values.

Stability of Ascorbic Acid in Dehydrated Vegetables

In the interesting leading article on "Food Storage and Transport" in Nature of August 22, 1942, there is a statement that "dried vegetables keep their ascorbic acid for some months when exposed to air". Clearly the stability of ascorbic acid in dehydrated vegetables, which will usually be consumed several months after manufacture, is of essential importance and needs careful investigation. Tests carried out on material immediately after dehydration give little indication of its antiscorbutic value under war conditions.

In recent experiments carried out in my laboratory, commercially dehydrated (steam-blanched) vegetables were kept for several months in an incubator at 37° C. in sealed (not exhausted) tins. The tins, containing samples from a consignment of each of the vegetables processed on one particular day, were opened at intervals for testing. It was found that dehydrated cabbage, cauliflower, and knol-khol lost 50 per cent of the ascorbic acid originally present in the dehydrated material in 12 weeks. The samples were stored at 37° C. to simulate tropical conditions. In other samples of these vegetables stored in closed but not sealed tins at Coonoor room temperature (say 18°–23° C.), the loss was 70–75 per cent in 6 weeks.

These samples took up some moisture, which may have accelerated destruction of ascorbic acid; the vitamin appears to be more stable in material which remains *crisp*. In a sample of dehydrated potato stored at room temperature in an unsealed closed tin the loss was only 10 per cent in 12 weeks. The stability of vitamin C in dehydrated vegetables in relation to conditions of packing and storage, the method of 'scalding', time of dehydration, etc., obviously requires further investigation.

Even in dehydrated amla fruit (*Phyllanthus emblica*), powdered, in tablets, and vacuum-packed, steady though slow loss of ascorbic acid occurs on storage. Amla, unlike common vegetables and fruits, contains tannins which have a protective effect on ascorbic acid. The loss in amla is slower than in the case of common vegetables, but the fact that loss does occur under such conditions suggests that ascorbic acid is unlikely to be very stable in other dehydrated vegetables and fruits not packed in containers from which oxygen has been excluded.

Urea Synthesis in Mammalian Liver

BACH and Williamson[1] claim to have shown that rat liver forms urea from ammonium lactate even when the activity of arginase is inhibited by high concentrations of ornithine[2]. They conclude that liver can synthesize urea without the participation of arginase.

The data presented by Bach and Williamson are capable of a different interpretation. A relevant feature of their experiments is the extraordinarily low activity of arginase. According to their graphs 3 and 4, 1 mgm. liver (wet weight) formed 1·26 μgm., or 0·75 μgm., urea per hour, the first figure referring to an arginine concentration of 12·4 mgm. per cent, the second of 7·5 mgm. per cent. The potential arginase activity of rat liver under similar conditions, that is, at the same arginine and *p*H, is shown in Table 1[3].

TABLE 1. ARGININE ACTIVITY OF RAT LIVER AT DIFFERENT ARGININE CONCENTRATIONS (*p*H 7·4; 0·025 *M* PHOSPHATE BUFFER; 4 ML. TOTAL VOLUME; 40 MINUTES INCUBATION AT 40°).

Concentration of arginine	Urea nitrogen formed by 1 mgm. (wet weight) ground rat liver
1112 mgm. per cent	369 μgm.
556 „	371 „
278 „	347 „
139 „	265 „
69·5 „	180 „
34·8 „	117 „
17·4 „	75 „
8·7 „	43 „

TABLE 2. ARGINASE ACTIVITY IN THE EXPERIMENTS OF BACH AND WILLIAMSON COMPARED WITH POTENTIAL ARGINASE ACTIVITY.

Arginine concentration	Arginase activity (μgm. urea nitrogen formed per mgm. wet liver per hour)	
	Potential activity	Bach and Williamson
12·4 mgm. per cent	88	1·3
7·5 „	63	0·8

The comparison of the arginase activity observed by Bach and Williamson with the potential activity obtained by graphical interpolation from Table 1 shows that no more than a minute fraction—about 1·3 per cent of the total arginase—was active in the experiments of Bach and Williamson (Table 2); presumably it was only the arginase from the surface layer of the slices or from disintegrated cells which reacted. The inhibition by ornithine refers to this fraction only. The bulk of the tissue arginase—more than 98 per cent—did not come into play in the inhibition experiments of Bach and Williamson. These, therefore, do not show that the arginase in their liver slices was inhibited, and it is thus unnecessary to conclude that there is a urea formation without arginase.

[1] Bach, S. J., and Williamson, S., NATURE, **150**, 575 (1942).

[2] This inhibition was first observed by R. E. Gross (*Z. physiol. Chem.*, **112**, 236; 1920). L. Hellerman and C. C. Stock (*J. Biol. Chem.*, **125**, 771; 1938) suggest that it may be due to the formation of metallic complexes of ornithine.

[3] The activities vary somewhat with sex, age and other factors, but are always of the same order of magnitude (see E. Baldwin, *Biol. Rev.*, **11**, 247; 1936; H. D. Lightbody, *J. Biol. Chem.*, **124**, 169; 1938).

IT seems scarcely possible to compare the activity of arginase observed with intact cell material suspended in bicarbonate buffer with that of ground tissue in phosphate buffer. There is also no linear proportionality between arginase activity and weight of slices[1].

If part of the arginase activity in the experiments with slices was caused as Krebs suggests by 'disintegrated cells', this criticism could surely be more justifiably applied to his experiments with ground tissue.

Krebs's criticism leads to the assumption that the 'tissue arginase' is incapable of decomposing added arginine but is active in the formation of urea from added ammonium lactate (via arginine). No explanation is given for this hypothetical difference.

Details of our work will be given elsewhere in due course.

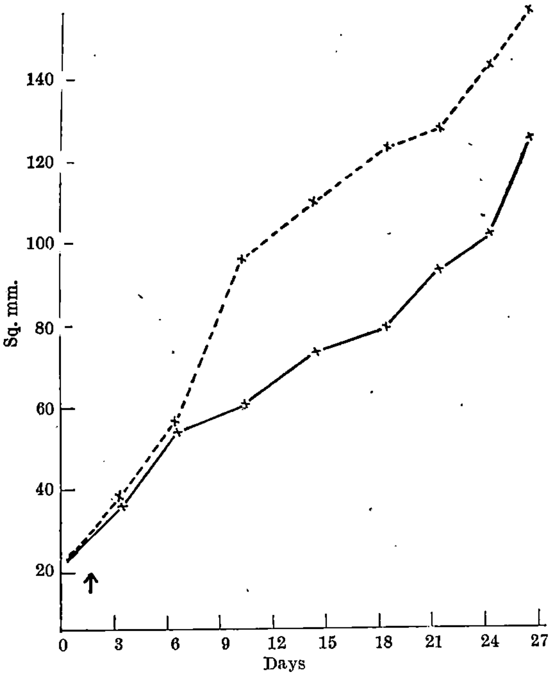
Growth Stimulators in Urinary Extracts

IN a recent communication by Werner and Doljanski, the growth-promoting effects of certain tissue extracts upon tissue cultures are described[1]. The methods of extraction indicate that the active extracts may contain protein or protein-associated groups.

It may be of interest to note that in the fractionation of the growth-inhibiting extract of urine, H. 11 Extract[2], which is now being used in the treatment of cancer, certain fractions have been obtained which are stimulatory to the growth of transplanted tumours. Such fractions are protein-free and can contain only substances of relatively low molecular weight. It therefore seems likely that non-protein growth-promoting substances are present in the tissues.

An example of such a stimulatory solution is that obtained when neutral H. 11 Extract is fractionated by precipitation with copper salts. Extraction of this precipitate with dilute hydrochloric acid yields an insoluble tarry substance which is partially soluble



- - - - - - - Treated (average of 7 tumours).
———— Untreated (average of 10 tumours).

Extract given in doses of 0·5 c.c. b.d. intraperitoneally. First injection 11 days after inoculation.

Tumour size evaluated as product of two diameters.

in sodium hydroxide. The alkali-soluble part is found to be growth acceleratory, as indicated by the accompanying graph.

As these results were only incidental to the main research on substances inhibitory to cancerous growths, no further investigations were made. It is felt desirable, however, to record them for the use of other research workers in this field.

The 'Age' of Terrestrial Matter and the Geochemical Uranium/Lead Ratio

IN 1937 Stefan Meyer[1], of the Radium Institute in Vienna, using the data then available, obtained a value for the 'age' of the sun, or rather of terrestrial matter (assumed to be of solar origin). Assuming matter to have taken on its present elementary composition when radioactive disintegration was also started, Meyer calculated the length of time required for producing all the uranium- and actinium-lead in existence through disintegration of uranium I and of actino-uranium respectively. In his calculation Meyer made use of the figures for the isotope ratios of uranium and lead determined by the mass spectrograph, and also of the geochemical uranium/lead ratio worked out by Goldschmidt. Finally, he assumed the activity ratio between the uranium and the actino-uranium series to be as 25 : 1. The result gave $(4 \cdot 6 \pm 0 \cdot 4) \times 10^9$ years as the age of the sun and, incidentally, the half-period of actino-uranium was found to be $(7 \cdot 0 \pm 0 \cdot 5) \times 10^8$ years.

Thanks to recent very accurate measurements by J. O. Nier[2], it is now possible to revise these calculations. Also the half-period of U^{235} has been found by independent methods ($7 \cdot 1 \times 10^8$ years). Using the latter value, the calculation can be carried out without using the hypothetical value of the geochemical uranium/lead ratio, which can be determined instead through the calculation. From Nier's determination the following constants are used: Isotope ratio of lead $Pb^{204} : Pb^{206} : Pb^{207} = 1 \cdot 5 : 22 \cdot 6 : 22 \cdot 6$; Decay constant of actino-uranium, $\lambda_{acu} = 9 \cdot 72 \times 10^{-10} a^{-1}$; Isotope ratio of uranium, $\frac{U^{238}}{U^{235}} = \beta = 139 : 1$.

From the law of radioactive decay it follows that:

$$\lambda_U t_a = \ln U_a / U_0. \quad . \quad . \quad . \quad . \quad (1)$$

If U_a was the number of uranium atoms t_a years ago and U_0 their present number, we find

$$U_a = U_0 + \alpha_u \Sigma Pb. \quad . \quad . \quad . \quad (2)$$

From equations (1) and (2):

$$t_a = (1/\lambda_u) \ln(1 + \alpha_u \Sigma Pb / U_0). \quad . \quad . \quad . \quad (3a)$$

For the actinium we find a similar equation

$$t_a = (1/\lambda_{acu}) \ln(1 + \alpha_{acu} . \beta . \Sigma Pb / U_0), \quad . \quad . \quad (3b)$$

where λ_u is the decay constant of uranium ($1 \cdot 535 \times 10^{-10} a^{-1}$), α_u the ratio $Pb^{206} / \Sigma Pb = 0 \cdot 226$ and α_{acu} the ratio $Pb^{207} / \Sigma Pb$ is $0 \cdot 226$.

By a graphical method we find from the preceding equations $t_a = 5 \cdot 33 \times 10^9$ years, whereas the geochemical lead/uranium ratio is found to be 5·6. It should be observed that the latter figure is derived directly from the radioactive constants. It agrees fairly well with Goldschmidt's assumption that per 100 atoms of silicon there are 0·0008 atoms of lead and 0·00016 atoms uranium present, giving a lead/uranium ratio of 5 : 1. We further find the present-day lead/actino-uranium ratio to be 750 : 1, whereas the uranium/urano-actinium ratio at the starting point, 5·33 billions of years ago, should have been as 1·78 : 1.

The age of matter thus found is seen to agree with the short-time scale now generally adopted in cosmic physics. It is of the same order of magnitude although numerically less than the new maximum age for iron meteorites given by Paneth[3] at $7 \cdot 8 \times 10^9$ years.

The figure here found for the age of terrestrial matter obviously represents a *maximum*, since any non-radioactive genesis of the lead isotopes Pb^{206} and Pb^{207} would mean a corresponding reduction in the time required for their production through disintegration. On the other hand, the age as stated only applies to the uranium isotopes, leaving the possibility open that when they were evolved the other elements may have existed for an indefinite time.

Effect of Air Currents, Light, Humidity and Temperature on Slugs

In view of the communication by Kalmus[1], it is of interest to record a brief summary of results obtained during an attempt to determine the causes of activity in slugs. The results will be considered under four headings, namely, responses to (1) air currents, (2) light, (3) humidity, and (4) temperature.

(1) *Air Currents.* A gentle draught of air (just perceptible to the observer's cheek) was played across the path of slugs (*Agriolimax reticulatus* and *Limax maximus*) just in front of the animals. The slugs turned away, going through the following movements. The tentacles were withdrawn, the head moved to right or left and the tentacles extended again. This process was repeated until the tentacles eventually remained extended and the animal moved away from the draught, presumably because the tentacles were no longer stimulated. Air played on the tail or body of the slug increased the speed of locomotion or, if the animal was at rest, induced activity. The same result was obtained using saturated air, showing that the effect was not due to the temperature drop (see below) caused by the evaporation of water which occurs when dry air is used. Air currents thus have a dual effect: (*a*) stimulation of the tentacles affecting the direction of locomotion, and (*b*) stimulation of the body or tail affecting the occurrence or speed of locomotion.

The above effects were readily demonstrated on a specimen of *Limax maximus* moving over a glass plate. Observation of the sole showed that stimulation of the tentacles by air currents involved immediate inhibition of the locomotory waves, while stimulation of the body or tail initiated waves or increased their speed. This inhibition of the locomotory waves by anterior stimulation is in accord with experiments in which a posterior half of a slug, completely severed from the head end, produced locomotory waves without ceasing for two hours after isolation.

(2) *Light.* In some instances slugs (*A. reticulatus*) kept at constant temperature in the dark showed increased activity when illuminated by electric light, though the increase was never as marked as in the temperature responses described below. The effect was short-lived, adaptation occurring quickly. In the final experiments using 72 animals at a time and noting activity at 15-minute intervals (instead of 5-minute as in previous experiments) no effect was obtained, possibly because adaptation occurred within 15 minutes. (In considering these experiments it is necessary to remember that a light was used for taking the readings in the dark, and the animals were thus illuminated for occasional short periods (1–2 minutes). The animals showed a typical avoiding reaction at the boundaries of well-defined regions of bright light. The boundary was, however, traversed if this was the only way in which the slug could avoid facing into a draught (see above).

(3) *Humidity.* At room temperature (16–18° C.) slugs (*A. reticulatus*) were found to be no more active at high than at low humidities. No orthokinesis comparable with that described by Gunn[2] in the woodlouse or by Pielou and Gunn[3] in the mealworm was observed. Slightly greater activity was obtained at low humidity. This may be explained as a response to the fall in temperature (see below) which occurs when a damp object is introduced into a dry atmosphere.

Humidity might affect the animals indirectly by altering their water content. Experiments on *A. reticulatus* and *L. maximus* showed that when loss of water by evaporation and mucus production exceeded a certain minimum value, the distance moved after the animal was transferred to an arena was reduced. The nature of the normal habitat of slugs makes it unlikely that such a reduction in water content would occur owing to evaporation alone, particularly as slugs can be shown to absorb water readily from damp objects with which they are in contact. Loss of water by mucus production may affect the occurrence of activity, and since mucus is produced during locomotion, may also limit its duration. Howes and Wells[4] observed weight fluctuations due to water content in *Arion ater* living under laboratory conditions but made no correlation with activity.

(4) *Temperature.* Slugs (*A. reticulatus*) respond readily to temperature changes. No correlation was observed between degree of activity and temperature when the latter was kept constant. Activity was, however, invariably stimulated by rising temperature above a critical value of about 20° C. Below this value the effect was reversed and activity stimulated by falling temperature. (In both cases the rate of rise or fall was about 1° C. in 10 minutes.) If the temperature was kept constant at any value, the activity fell to a low level. Some evidence has been obtained that temperature changes towards the critical value of 20° C., that is, in the reverse direction to those above, reduce activity below the level observed at constant temperature.

The results of these and related experiments will be published in detail elsewhere.

Discoveries by Accident

It is not derogatory of a discoverer to say that his discovery arose from an accident; for the power to use accidents, events the occurrence of which was not intended, is the mark of one form of scientific genius. Probably all experimenters are presented with about the same number of accidents which, if they had had the wit, would have led them to important discoveries; but most of us fail to appreciate their significance until the discovery has been made by somebody else; we may then fail to remember them or forget them to save our self-respect. I know that I had at least three such accidents that would certainly have led Röntgen to discoveries, if not as important as X-rays, at least of considerable technical and scientific interest. Two of them I missed entirely, and the third I used very imperfectly.

Doubtless there is another form of scientific genius that proceeds from triumph to triumph according to an ordered plan; but it is seldom certain that the progress was really as orderly as it appears when the results are presented. Even if this form must be reckoned the higher, science would never have reached its present position without the other.

RESEARCH ITEMS

South African Bored Stones

A. J. H. GOODWIN, of the University of Cape Town, has given an account of the bored stones of South Africa in No. 1 of the new series of Communications from the School of South African Studies published by the University of Cape Town. Bored stones are of various kinds—as described in the article—but, generally, may be visualized as balls of stone so pierced that they can be hafted on to sticks, which are then used for digging or other purposes, the weight of the stone materially assisting the operation. The age of these bored stones varies considerably, some being quite modern and some of unknown antiquity, and culturally speaking they have been used by Bantus, Bushmen and prehistoric peoples. They are figured in some of the so-called Bushmen paintings. The present article analyses a large amount of material and will be very useful for reference purposes to students of South African Stone Age archæology.

New Palæolithic Industry from East Anglia

AN interesting paper on a new palæolithic industry from the Norfolk coast appears in the *Geological Magazine* (79, July–August 1942) under the names of D. F. W. Baden-Powell and J. Reid Moir. The problem of the number and relationships of the various glacial deposits in Norfolk has evoked much literature, but this short article may well be preferred to some of the longer treatises. For the first time, the Corton sands at Corton are properly taken into account and correlations made between the deposits there and at Hoxne. A very interesting flint industry found in the "Corton" sands at Runton and hence named *Runtonian* is also described. The artefacts are apparently usually small and include neatly trimmed round scrapers, points, etc. The whole industry might perhaps be assigned to an early Clactonian culture since it certainly belongs to the flake-tool culture group, and plain, unfaceted striking platforms are the rule. It is to be hoped that Baden-Powell and Reid Moir will not rest content with this small article; it should be treated as a synopsis to a more comprehensive work on the prehistory of these parts of East Anglia.

Biology of the Brown Trout

THE results of the research by A. E. J. Went and Winifred E. Frost form the fifth of the series of the survey of the River Liffey begun by the late Rowland Southern and continued after his death in 1935 by Miss Frost (River Liffey Survey, V. Growth of Brown Trout (*Salmo trutta* L.) in Alkaline and Acid Waters. *Proc. Roy. Irish Acad.*, 48, B, No. 4; 1942). Variation in the size of brown trout from different localities has given rise to much discussion. In general, in waters of low *p*H values the trout were small and slow-growing, whereas in limestone waters they were of the large quick-growing type. The present work is based on sets of scales together with other data relating to length, weight, sex, date of capture, etc., most of which have been collected by Miss Frost from brown trout taken by angling in the River Liffey and its tributaries. The main part of the material was obtained from Straffan (alkaline water, mean *p*H 7·9) where the trout were of relatively large size, and from Ballysmuttan (acid water, mean *p*H 5·5) where they are seldom more than four ounces in weight. It is suggested that the difference in growth-rate in the two localities is mainly due, not, as it is often considered, to the age of sexual maturity, which is found to differ little, but to a longer period of rapid (summer) growth and more active growth during the period of slow (winter) growth at Straffan than at Ballysmuttan.

Subantarctic and Antarctic Algal Communities

C. SKOTTSBERG describes the communities of marine algæ in subantarctic and antarctic waters (Kungl. Svenska Vetenskapsakademiens Handlingar. Tredje Serien. 19, No. 4; 1941). The work is based on his personal observations during the Swedish Antarctic Expedition (1901–1903) and the Swedish Magellanic Expedition (1907–1909). The algal communities were practically unknown in the regions visited except that the 'kelp belt', the association of *Macrocystis pyrifera*, had attracted attention for centuries. This, the most famous of all southern communities, ranges from the Peruvian coast to Cape Horn and is circumpolar in the antarctic, forming a belt outside the breakers but approaching close to the shore in smooth waters. It was a great misfortune that the major part of the antarctic collection was lost with the ship in the pack-ice of Paulet Island. A large amount of work, however, has still been possible. The four districts concerned—South America from Chiloë to Fuego, the Falkland Islands, South Georgia and West Antarctica ("Graham Land")—are treated separately and there are distinct differences in the algæ of these regions. There are some interesting deep water communities. The red algæ dominate in deep water, whereas the littoral species often show a brownish violet tinge. The author believes that, judging from his own material, in the antarctic at least a small number of red algæ are able to exist at a depth greater than 40 m., especially as the Desmarestia association extends to almost this depth, but that there are no special deep-water species justifying the recognition of a separate elittoral algal region, and that records from below 50 m. need corroboration.

Genetics of the Potato

SEVERAL viruses of the potato cause a lethal necrosis of some varieties when these are grafted on to infected stocks. This necrosis only occurs on those varieties which are intolerant of the virus, and which rarely, if ever, carry the infection in the field. C. H. Cadman (*J. Genetics*, 44, 33–52; 1942) has shown that the products of top-necrosis due to virus X after grafting occur in those varieties which carry a dominant gene Nx. This gene segregates in an autotetraploid manner; the occurrence of equational exceptions and the statistical examination of the segregation ratios show that Nx is situated far from the centromere. It should be possible to raise varieties which are intolerant, that is, practically immune from virus X.

Great Iron Boulder from Ovifak

H. Löfquist and C. Benedicks give a detailed account of the core from the great iron boulder brought by Nordenskiöld from Ovifak to Stockholm ("Det Stors Nordenskiöldska Järnblocket fran Ovifak: Microstructur och Bildningssätt." Kungl. Svenska Vetenskapsakademiens Handlingar. Tredje Serien. 19, No. 3; 1941). This huge mass of 25 tons belongs to the Mineralogical Department of the State Museum of Natural History (Riksmuseet) and was successfully drilled out in 1938. The core obtained was divided into five specimens and a complete metallographic investigation was made. Chemical analyses of samples taken close to these specimens show that the iron boulder consists of nickel-bearing, sulphur-rich massive iron with a high carbon content, making a natural raw iron. The microstructure, on the whole, agrees well with the analytical results, and minute investigations were made on all the constituents. The general conclusion is that there are strong reasons for the view that the iron boulder has been formed from iron sulphide to which carbon has been added. The genesis of the Ovifak boulder may be explained as the result of the following contact-metamorphosis: "One of the boulders of the nickeliferous pyrrhotite of the neighbourhood has happened to be enclosed in a crack in which molten basalt has risen, after having absorbed carbon from the coal beds broken through. . . . Under the combined action of the high temperature of the magma and its carbon, the sulphides of the pyrrhotite have been dissociated, giving carbon-rich iron, i.e., a natural crude iron containing nickel, being Ovifak iron." This work is in Swedish with an English summary.

Crystal Structure of Phosphorus Pentachloride

THERE is proof from electron diffraction experiments that the molecules of some phosphorus pentahalides have the configuration of a trigonal bipyramid, and the same configuration is found for a number of other molecules of similar formula. The appreciable electrical conductivity of solutions of phosphorus pentachloride and other observations suggest that it may be able to exist in an ionized form. The physical properties of the solid lend support to this idea, and a comparison of the Raman spectra in various states shows that the bipyramidal molecules do not persist in the solid. An examination of the X-ray spectrum by D. Clark, H. M. Powell and (independently) A. F. Wells (*J. Chem. Soc.*, 642; 1942) has now given the very interesting result that in the crystal the substance exists in ionic form. The unit cell is tetragonal and contains tetrahedral PCl_4^+ and octahedral PCl_6^- groups. These are arranged in a structure essentially of the cæsium chloride type, but distorted, since the ions are not spherical. The structure bears some resemblance to that of tetramethylammonium iodide but belongs to a lower symmetry class of the tetragonal system. The phosphorus to chlorine distance varies from 2·06 A. in PCl_6^- to 1·98 A. in PCl_4^- and is interpreted as related to change of effective nuclear charge. The P to Cl distance in PCl_4^+ is short by about 0·08 A. of the length calculated from the sum of the normal tetrahedral covalent radii derived from methyl compounds, with a correction for charge. Similar shortenings have been observed for many halogen compounds.

Estimation of Added Calcium Carbonate in National Flour

AT a meeting of the Society of Public Analysts and Other Analytical Chemists held on November 4, E. N. Greer, J. D. Mounfield and W. J. S. Pringle described "The Estimation of Added Calcium Carbonate (Creta Praeparata) in National Flour". Three methods have been studied and are described: (*a*) The sample is incinerated and calcium is determined in the ash by precipitation as oxalate and titration with permanganate; a blank estimation should be made on a sample of the same flour without added Creta. (*b*) The sample is treated with excess of standard hydrochloric acid and the excess titrated back with alkali; with this method also a blank estimation is necessary. (*c*) The carbon dioxide liberated by excess of hydrochloric acid is absorbed and weighed. If a control sample of the unfortified flour is available, the oxalate method is the most accurate; without a control sample the error may be as much as 20 per cent. Method (*b*) also requires a control sample and when the amount of Creta is about 7 oz. per sack the method is accurate to 3–4 per cent. Method (*c*) is accurate to within about 3 per cent even in absence of a control, and this method is therefore the most useful of the three.

Crystal Structure of Graphite

A FURTHER discussion of the faint extra lines found on X-ray powder photographs of well-crystallized graphite by Taylor and Laidler (NATURE, 146, 130; 1940) is given by H. Lipson and A. R. Stokes (*Proc. Roy. Soc.*, A, **181**, 101; 1942). A new structure is proposed having hexagonal layers similar to those of graphite, but arranged in a different sequence. About 14 per cent of the new structure is present in the samples examined, ranging from natural graphite from Ceylon, Bavaria and Travancore to graphite extracted from the 'kish' occurring in the casting of carbon-rich steels as well as in graphite crystallized by arcing.

Obscured Regions in the Greenwich Astrographic Zone

IN a paper on this subject (*Mon. Not. Roy. Astro. Soc.*, **102**, 5) E. G. Martin gives the results of the separate counts for the Greenwich region (Dec. +64° to +87°, galactic latitude +4° to +51°), originally published in vol. 4 of the *Astrographic Catalogue*. A comparison of the average log N_m at different latitudes and longitudes with the figures by van Rhijn provides some very interesting results. The frequency curve shows that there is a considerable amount of asymmetry, negative residuals being in excess. On the assumption that the scatter is due to accidental error, the probable error in log N_m of a single count for regions at latitudes exceeding 25° is $\pm 0{\cdot}102$, and for those less than latitude 25° it is $\pm 0{\cdot}122$. There are twenty-nine regions in which the negative residuals are larger than three times the probable error, the largest residual being eight times the probable error, and it is considered that this is due to a real absorption effect. Nineteen of the outstanding regions are spaced in latitudes 4° to 20°, and only ten lie between latitudes 20° and 50°; this confirms the hypothesis that absorption increases towards the galactic equator. Among the five strips selected in galactic longitude to derive the separate mean values of log N_m, it was found that there is a tendency for the central strips to contain more outstanding regions than the outer strips, indicating a higher absorption around longitude 90°–100° and confirming a secondary maximum. It is very difficult to determine how much the absorption for each individual count amounts to in magnitude and also to find at what distance the absorption is effective, owing to the fact that actual counts are available only from magnitudes 10 to 13. An attempt was made to analyse the mean results of the counts for latitude 7°, and, while the result showed a density near the sun similar to that given by van Rhijn up to 1,000 parsecs, at 10,000 parsecs the density rapidly increased to a much larger value than that of van Rhijn.

TRACE ELEMENTS IN RELATION TO HEALTH

THE eighth scientific meeting of the recently formed Nutrition Society, or fifth of the English group, took the form of a whole-day conference at the London School of Hygiene and Tropical Medicine, on "Trace Elements in Relation to Health".

Dr. J. Russell Greig occupied the chair at the morning session, opening the proceedings with a brief reference to his own interest in 'pining' of sheep in Scotland. Prof. C. Harington took the chair at the afternoon session and finally summed up the day's discussion as a whole. Ten papers provided by fourteen contributors were included on the agenda paper, all of which will be published in due course in the *Proceedings of the Nutrition Society*.

(1) *Significance of Trace Elements in Relation to Diseases of Plants and Animals.* In this paper Dr. H. H. Green, of the Veterinary Laboratory of the Ministry of Agriculture at Weybridge, offered a 'bird's-eye view' over the whole field of trace elements of known economic importance in both plant and animal life, intended to serve as an introduction to the more specialized papers to follow. Commencing with a definition of 'trace element' as any element regularly occurring in minute amounts in living tissues whether it exercises any specific physiological function or not, metals such as aluminium and nickel were cited as apparently inert and merely present because incidentally taken up by the action of plant roots; elements such as copper and manganese cited as essential for both plants and animals, boron as essential for the plant but not known to be essential for the animal, cobalt as essential for cattle and sheep but not yet known to be essential for non-ruminants or for plants, selenium and molybdenum as probably unessential for both plants and animals but sometimes taken up by healthy plants in amounts which cause disease in the consuming animal.

Omitting elements such as lead and arsenic which, though known to be toxic, are not absorbed by plants in amounts dangerous to animals, and passing over the essential element iodine as "trace but no longer novel", the elements copper, cobalt, manganese, zinc and boron, were dealt with in some detail as involved in deficiency diseases, and fluorine, selenium and molybdenum as causing toxicoses.

The occurrence of relevant plant and animal ailments in various parts of the world was summarized, local names, prominent symptoms and methods of control being mentioned. Control varies from fertilizing apple trees with borax in Tasmania for control of 'internal cork', or pine trees in Australia for 'needle fusion', top-dressing pastures with copper sulphate for control of 'Urbarmachungskrankeit' in crops and 'Lecksucht' in animals in Schleswig-Holstein, or for control of 'falling disease' of ruminants in Australia, providing copperized salt licks to breeding sheep for protection against 'sway-back' of lambs in England or 'enzootic ataxia' in other parts of the world, supplying cobalt to prevent 'wasting disease' of cattle and sheep in Australia, 'Grand Traverse disease' in Michigan, and 'pining' in Scotland, to controlling the 'alkali disease' of Dakota or the 'blind staggers' of Wyoming by eradicating plants which take up excessive quantities of selenium from seleniferous shales and act as 'selenium converters' by finally returning that toxic element to the soil in a form more available for other plants.

The quantities of essential trace elements in plants are, however, no necessary indication of the quantities required by consuming animals, and animals may waste away when grazing on luxuriant herbage or complete the cycle of their being on plants showing obvious symptoms of vegetative failure.

(2) *Distribution of Trace Elements in Soils and Grasses.* Dr. R. L. Mitchell, of the Macauley Institute, near Aberdeen, pointed out that a very large number of elements is present in soils, each in traces of fractional parts per million upwards, but that the amount of any one of them may vary a thousand-fold from soil to soil. The variations correspond to the parent material from which the soil is derived, in the last resort from igneous rocks and the magmas from which they have crystallized; but certain geochemical rules prevail, and if any particular trace element occurs in a rock there must be present in it a mineral at least one of the constituents of which can be replaced by an atom of the element in question. For this reason elements such as cobalt, nickel and chromium would be expected in higher quantities in ultrabasic rocks than in acidic rocks, where elements such as barium would be more prevalent. If the origin of a soil can be directly traced to an igneous formation, it is possible to forecast the probable occurrence of its trace elements, but in practice the problem is complicated by weathering and metamorphosis and if, as often the case in north-east Scotland, the surface is derived by glacial drift from sedimentary rocks, the problem becomes individual for each soil considered. These points were illustrated by discussing the range of trace elements found by spectrographic analysis of Scottish soils, in respect of silver, barium, cobalt, chromium, cæsium, copper, gallium, germanium, lanthanum, lithium, manganese, molybdenum, nickel, lead, rubidium, tin, strontium, thorium, titanium, vanadium, yttrium and zirconium.

The occurrence of a given trace element in a soil, however, is not necessarily a guide to its occurrence in plants, and although there exists a general correlation between soil quantities soluble in dilute acetic acid and quantities found in the covering vegetation, trace-element deficiency diseases are sometimes found in plants growing on soils containing abundance. The natural *p*H of the soil is an important factor, as evidenced by the lime-induced 'chlorosis' of plants found in parts of England.

In general, trace-element deficiencies of plants and grazing animals can be rectified by incorporating small amounts in fertilizers, as little as 2 lb. per acre of a cobalt salt being sufficient to prevent the 'sheep pining' of certain pastures in Ross-shire. Among plant diseases in Scotland associated with trace elements were mentioned boron deficiency of turnips and sugar beet in the west and manganese deficiency leading to 'oat sickness' in the north.

(3) *Copper, Zinc and Other Trace Elements in Relation to Physiological Function and Enzyme Systems.* Dr. H. Mann, in this paper with Prof. D. Keilin, pointed out that, of the numerous trace metals detectable in tissues, definite physiological functions have so far only been assigned to iron, copper and zinc. To these, several distinct purposes can be assigned, of analogous character in all three cases. They either form oxygen carriers or catalyse reactions involving oxidation, reduction, or acid-base equilibrium. In each case the metal has definite physiological properties only when stoichiometrically bound with highly specific protein molecules which, although themselves inactive, determine the pro-

perties of the metallo-protein compounds and can be limiting factors in their formation. It is the specific protein which determines whether the trace element is to function as carrier of molecular oxygen in the circulating fluid or as catalyst promoting intracellular oxidation in the tissues, or perform any other function.

In dealing with iron, Dr. Mann discussed the rare iron-protein hæmerythrin, the commoner iron-porphyrin-protein oxygen-carrier hæmoglobins and myoglobins, the green hæmoglobin chlorocruorin of certain molluscs, and the oxidizing catalysts cytochrome, peroxidase and catalase. Among the copper-protein compounds are the blue oxygen-carrier hæmocyanins of some arthropods and molluscs, the oxidizing catalysts such as the phenolic oxidases which account for the rapid darkening of fruits and vegetables on bruising, and of insect cuticle after emergence from the pupæ. The function of the hæmocuprein of red blood cells is not yet known, although copper is recognized as essential for hæmoglobin formation. In the case of zinc, only one enzyme is yet recognized, the carbonic anhydrase of blood corpuscles, gastric mucosa, pancreas and other tissues. Its function is to catalyse the reversible dissociation of carbonic acid into carbon dioxide and water, and so facilitate the removal of oxidation products and the maintenance of acid-base equilibrium in the body. The fact, however, that the distribution of zinc is not strictly coincident with that of carbonic anhydrase suggests other zinc-protein compounds with other functions.

Of special interest is the enormously high activity of the trace metals in the form of their specific protein compounds. The enzymes are active when present as parts per thousand million, a level at which neither the metal itself nor the protein itself can be detected by any known chemical means.

(4) *Enzootic Ataxia or 'Swayback' of Lambs in England in Relation to Copper Feeding of Ewes During Pregnancy.* This contribution took the form of a cinematographic film illustrating the Derbyshire investigations of a group of workers under the general co-ordination of Prof. T. Dalling, recently translated from the chair of animal pathology at Cambridge to the directorship of the Veterinary Laboratory of the Ministry of Agriculture at Weybridge, into a disease of lambs termed 'swayback' in Britain and 'enzootic ataxia' in Australasia and other parts of the world. The disease can be controlled by supplying copperized salt during pregnancy to outwardly healthy ewes, the lambs of which otherwise develop the disease during fœtal growth and suffer high mortality incidence in the first week of life. Although the precise role of copper is not yet clear, the quantities of that element in the blood of affected lambs and their mothers is below that of unaffected controls. Unlike certain Australasian pastures, however, affected Derbyshire pastures cannot be incriminated as grossly deficient in copper.

The film illustrated the characteristic spastic paralysis of limbs with resultant inco-ordination during life, and the pathological lesions found at post-mortem. The latter comprised symmetrical demyelination of the cerebrum and secondary degeneration of the motor tracts of the cord.

(5) *Cobalt and Other Trace Elements in Relation to Disease in Australasia.* This paper, read by Dr. H. Chick on behalf of Sir Charles Martin, who had personal experience of animal diseases in Australia during his sojourn there about a decade ago. placed in historical perspective the classical researches carried out over the last fifteen years in that continent into diseases of cattle and sheep caused by deficiency of cobalt, of copper, or of both combined.

Along the coast of South and West Australia, areas occur in patches long known by farmers to be unsuitable for rearing ruminants, although they enjoy a rainfall of 20–40 in. and produce abundant herbage throughout the growing period. Animals could be fattened on them but not reared, since if confined to them for more than a few months cattle and sheep began to weaken, without characteristic lesions to suggest a cause, finally dying of starvation in the midst of apparent plenty. In South Australia the soil of these unsound areas consists of unconsolidated wind-blown sand and shells; in West Australia of loamy granitic gravel about five miles from the coast at an altitude of 500 ft. In the latter area the disease was termed 'enzootic marasmus' by Filmer, who found that, like the 'bush sickness' of New Zealand formerly attributed by Aston to iron deficiency, it can be prevented and cured by mineral licks containing the iron ore limonite. Very poor response, however, was given by therapeutic treatment with pharmaceutical iron salts, and in following up this observation Filmer subjected the limonite to chemical fractionation. Extracts freed from iron but containing zinc, nickel and cobalt were as active as the original material and trials of these elements separately led to the discovery that enzootic marasmus is a cobalt-deficiency disease preventable by administration of so little as 0·1 mgm. daily for sheep and 0·5 mgm. for cattle.

Parallel researches by Marston and others in West Australia were complicated by differences in symptomatology. In addition to the progressive weakness of enzootic marasmus, ataxia proceeding to complete inco-ordination of limb movements was observed, particularly in lambs and young sheep, and shown by Bull to be associated with demyelination of spinal tracts. After much exhaustive testing of possible causes, from poisonous plants to gross mineral imbalance, a trace element factor was suspected and Jansen's salt mixture, containing zinc, nickel, cobalt, manganese, aluminium, boron, arsenic, molybdenum and copper, along with the usual major elements, was tried. This gave excellent results, and by a process of elimination it was finally ascertained that the required combination was copper and cobalt. Unless both were included the experimental controls succumbed within a year.

Further investigation showed the occurrence of copper deficiencies alone, notably the enzootic ataxia of lambs in West Australia, while the bush-sickness of New Zealand was then found to be due to deficiency of cobalt and not iron. Arising from the Australasian investigations, similar diseases were then identified in many other parts of the world, including the long known 'renguerra' of Peru and the 'swayback' in restricted areas of England.

(6) *Sheep 'Pining' in Britain.* Mr. W. Lyle Stewart, veterinary investigational officer at Newcastle, dealt mainly with the occurrence of 'pine' in Northumberland, a wasting disease of sheep associated with anæmia. This is treated as the result of interaction between malnutrition and helminth infestation. Neither factor alone is sufficient to account for death. In fairly large-scale experiments a small ration of mineralized cake containing a variety of trace elements, including copper and cobalt, reduced incidence of the disease, and periodic dosing with anthelmintics achieved the same effect, but much

the best results were obtained by combining both treatments. In another series of experiments equally good results were obtained by combining fortnightly dosing with mixed trace elements in solution and monthly dosing with phenothiazine as anthelmintic. Live-weight gains of lambs over a short experimental period were 27 lb. for the controls, 31 lb. for trace element dosing, 36 lb. for anthelmintic treatment, but 41 lb. for the combined treatments.

(7) *Fluorine in Human Nutrition.* Biochemical aspects were dealt with by Dr. M. M. Murray, a clinical account of fluorine distribution was provided by Dr. D. C. Wilson, and radiological investigations were reported upon by Mr. F. H. Kemp.

Dr. Murray dealt briefly with sources of fluorine in drinking water, the main cause of chronic endemic fluorosis manifested most clearly as 'mottling' of teeth; and with compounds such as fluorspar and cryolite causing industrial fluorosis, characterized by osteosclerosis. It was pointed out that fluorine occupies a curious position nutritionally in that very small traces appear to be beneficial, whereas larger traces seriously interfere with bone metabolism. More fluorine was found by American workers in sound teeth than in carious teeth, and 'mottled enamel', occurring where fluorine in drinking water reaches about 1 p.p.m. during the period of development of teeth, is more resistant to caries. Fluorine affects the bones at all ages; adult workers exposed to industrial risk develop osteosclerosis but not mottled teeth. Little is known about the precise action of fluorine, but the low concentration at which it inhibits osteogenesis suggests a catalytic effect. Traces of fluorine can pass the placental barrier, and disorganization of calcification occurs in the fœtuses of experimental rats on high fluorine intake.

Mr. Kemp showed lantern slides illustrating cases of human skeletal fluorosis, including 'round back' of children and adults in areas of Great Britain in which mottled teeth are prevalent. It was not claimed that high fluorine intake is alone responsible for interference with spinal ossification in children, but merely that high fluorine in drinking water may influence development of such defects.

Dr. Wilson discussed the relationship between fluorosis and nutritional status, stating that although mottling and staining of teeth are proportional to the amount of fluorine in drinking water, the state of nutrition of the individual determines the character of the enamel and regularity of dentition. Nutritional status also influences the skeletal lesions in chronic endemic fluorosis, and dietary surveys in India have shown much more severe lesions in poor villages than in prosperous neighbouring communities. For early treatment of 'round back' associated with dental fluorosis of children in Oxfordshire, good results can be expected by combining school meals with attention to posture in physical training.

(8) *Industrial Fluorosis of Animals in England.* Under this title Mr. F. Blakemore, veterinary investigational officer at Cambridge, described an outbreak of industrial fluorosis in farm animals extending for about a mile in the direction of the prevailing winds from a high concentration of kilns in a brick-making district of England. Analysis of pasture grass and other plants showed surface contamination with fluorine compounds and this was traced to the flue gases drifting down from the chimneys, and thence to the high fluorine content of the clay used in brick-burning. Cattle are most severely affected and typical cases show lameness and enlarged atrophic bones with fluorine content up to 16,000 p.p.m.; mottling of the permanent incisors occurs in most cattle within the affected belt. Urinary fluorine is high even in animals without pronounced clinical symptoms, and its estimation in catheter samples has proved an excellent method of mapping affected farms. On removal of clinically affected animals from the district, urinary elimination of fluorine continues above normal, with rapid clinical improvement. The content of fluorine in surgically removed bone fragments fell rapidly over the first three months, but over the following five months showed little change from the residual high level.

A few parallel observations in the Manchester smoke belt showed no evidence of fluorosis at all.

(9) *'Teart' of Somerset: a Molybdenosis of Farm Animals.* Mr. W. S. Ferguson, one of the three Jealott's Hill investigators who established the etiology of this disease a few years ago, described the condition as one only affecting ruminants, chiefly dairy cows, and characterized by scouring and progressive cachexia. The dung becomes watery, foul and greenish yellow; hair covering of Red Devon cattle turns dirty yellow, and that of black beasts a rusty colour. Affected areas comprise about 20,000 acres in central Somerset associated with the Lower Lias geological formation, and smaller regions in north Somerset, Gloucester and Warwick. Spectrographic examination of affected pastures reveals abnormally high molybdenum, up to 100 p.p.m. on the dry matter as compared with 5 p.p.m. for healthy pastures, and the degree of 'teartness' is directly related to the water-soluble molybdenum content, which is highest in lush young grass and lowest in old herbage. The analytical conclusions were supported by reproducing the disease experimentally, by dosing with calculated amounts of sodium molybdate and by top-dressing sound pasture to raise the molybdenum content to that of affected pastures.

In searching for an antidote, it was found that oral ingestion of 2 gm. copper sulphate per cow per day prevents scouring and permits grazing of teart pastures throughout the season. Explanation of the mode of operation of the copper, and of the limitation of the molybdenum effects to ruminants, awaits further investigation.

(10) *Absorption and Excretion of Trace Elements.* Miss E. M. Widdowson, reading a joint paper with Dr. R. A. McCance, pointed out that there are no special characteristics in regard to absorption and elimination of trace elements except in so far as these can be deduced from their known chemical properties. Both absorption and excretion of silver as a trace element are limited by the insolubility of its chloride; in the case of barium by the insolubility of its sulphate. If divalent and capable of forming insoluble phytates and phosphates, as in the case of zinc and manganese, they tend to behave like the physiologically abundant calcium. If monovalent and characterized by solubility of their salts, they behave like the alkali metals or the halogens. The soluble milligram or so of lithium in daily human food behaves exactly like the concomitant 5,000 mgm. of sodium. Elements which cannot be excreted by the kidney in virtue of attachment to serum proteins will react alike, and zinc or manganese will tend to behave in the same way as iron.

The difficulties inherent in determining absorption and excretion of any element while the cycle of ingestion, intestinal absorption and partial return to he intestine by bile and digestive juices is in progress were stressed, and further parallels drawn between relatively abundant elements such as calcium and magnesium and trace elements such as trontium, tin, cobalt and nickel.

In his final summary of the day's discussion, Prof. C. Harington reviewed a number of the salient eatures in the light of his own experience of the history of development of the physiology of iodine, tressing the point that although much information on the importance of various trace elements may accumulate, final conviction concerning the significance of any particular one does not really penetrate he scientific consciousness of the community until precise physiological function becomes clear and the actual operative mechanism is biochemically demonstrated.

T. DALLING.
H. H. GREEN.

STAR MAGNITUDES AND IMAGE DIAMETERS IN PHOTOGRAPHIC PHOTOMETRY

FORMULÆ hitherto employed to determine the relationship between star magnitudes and image diameters on photographic plates have been empirical, and fail in certain circumstances. It is impossible to apply them in the case of bright stars which give diameters larger than a certain limiting value (and his value varies with different formulæ) and, in ddition, the formulæ take no account of the effect f star colours. D. L. Edwards has described a new method of investigation which gives very satisfactory esults (*Mon. Not. Roy. Astro. Soc.*, **102**, 5). The work was carried out at the Norman Lockyer Observatory, Sidmouth. Three different Zeiss triplet lenses were used: (*a*) aperture 14 cm., focal-length 70 cm.; *b*) aperture 10·4 cm., focal-length 50 cm., (*c*) similar o (*b*) but stopped down to 2 cm. aperture. The plates used were the Barnet Super Press (blue sensitive mulsion), and Ilford Hypersensitive Panchromatic, which gives a good scale of photovisual magnitudes without a filter. When the panchromatic plates were onsidered and measured diameters were plotted gainst H.D. visual magnitudes (only stars of ype *A*0 being used to determine the form of the elation for one colour only) the empirical formula $m=a-b(D-kD^2)$ gave the best fit. In this formula m is the magnitude, D the diameter, and a, b, k are onstants.

Measures made on Barnet Super Press plates were reated in the same way, except that photographic instead of photovisual magnitudes were used, and it was found that the above relation held as for the photovisual plates. In addition, the same values f k were also applicable, in spite of the different magnitude scales and of the different types of mulsion used. Good values of k were given by $=10^{-5}(140-13C)$, where C is the colour index.

The advantage of the first formula given above is hat it has a greater range of application to bright tars than earlier formulæ, and it also allows for olour effect.

Edwards has applied this formula to γ Cassiopeiæ. The series of photographs extended over the period June 1, 1940, until March 24, 1942. During 1940 the magnitude variations were more pronounced, but by the end of the year and also throughout 1941 they tended to become steadier. Considerable changes in the spectrum accompanied the more pronounced fluctuations. At, and just preceding, the minima of June 29, 1940, photovisual magnitude 2·76 and photographic magnitude 2·64, and also of September 21, photovisual and photographic magnitude each 2·53, the *H* lines showed well-separated double emission components with strong central absorption and rather faint 'dish-shaped' absorption fringes. The He I absorption lines at 4471, 4026, 3964 were strong and sharp, and O II absorption rather faint. During the rise to maxima at August 24 and October 7, the magnitudes on these dates being $m_{pv}=2{\cdot}20$, $m_p=2{\cdot}06$, $m_{pv}=2{\cdot}05$, $m_p=2{\cdot}06$ respectively, the *H* central absorption became fainter and the 'dish-shaped' absorption stronger. The He I lines became fainter and more diffuse, OII became a little stronger, and λ 3888 (He I) very strong.

It was found that the colour index changes were subject to considerable uncertainty and did not show such pronounced correlation with spectrum changes as the magnitude variations. The mean colour index over the whole period was $-0{\cdot}12$, and corresponds to the average colour index of *B*6 stars. As γ Cassiopeiæ is a *B*2 star, the average colour index of which is $-0{\cdot}30$, its average colour index suggests considerable reddening.

ULTRA-SHORT RADIO WAVE PROPAGATION

AT a meeting of the Wireless Section of the Institution of Electrical Engineers on November 4, Dr. R. L. Smith-Rose and Miss A. C. Stickland read a paper describing the results of an analysis of field intensity measurements obtained during the years 1937–39, over the Post Office radio-telephone link between Guernsey and Chaldon, England, on wave-lengths of 5 and 8 m. (frequencies 60 and 37·5 mc./s.). The path between the radio stations was almost entirely over sea and about 85 miles in length, of which some 36 miles were outside the optical range. The material analysed was in the form of continuous, twenty-four hours a day, records of the field intensity received at Chaldon from the transmitters at Guernsey.

A quantitative study of the records confirmed the similarity of the type of signal fading on the two wave-lengths, and the lack of both diurnal and true annual variation; on the other hand, the results suggested a long-term secular variation in which the amount of fading on 5 m. tended to increase to a maximum over the period of observations while that on 8 m. decreased. The period of two years over which the observations were taken was not sufficient, however, to allow of any conclusions being formed as to an explanation of this trend.

Comparison with meteorological data showed a marked correlation between periods of very little fading and the presence of low-pressure systems, while periods of slow fading recurred at times of anticyclonic conditions. This, together with the fact that fading, while always less in winter than in summer, showed no regular seasonal variation, led to the conclusion that the winter decrease was due to the greater prevalence of low-pressure systems during this season.

A simple theoretical treatment of the propagation of waves through the lower atmosphere shows that account must be taken of the various paths by which rays can pass from transmitter to receiver, these rays being subject to diffraction, refraction or reflection on the way. The received signal is the resultant of the various rays received, and it is clear that interference effects may result from the arrival of two rays simultaneously by different paths. Sudden changes in the temperature and water vapour content in the atmosphere produce corresponding changes in refractive index and so cause marked bending of the rays transmitted. In regions of temperature inversion these conditions may be specially marked, resulting in the ray being completely bent over and returned to earth in a manner analogous to reflexion from a discontinuity.

An explanation of the lack of fading in bad weather and of the pronounced fading in good weather is sought in the fact that, in anticyclonic conditions, temperature inversions and associated sudden changes in relative humidity are usually present at heights of 1–2 miles, whereas in cyclonic or depression conditions these are absent. While the existence and diurnal variations of temperature inversions may be different over land and over sea, the general structure of the atmosphere in an anticyclone is probably the same in the two cases; in particular, changes in water vapour content may obtain over sea, which give rise to refraction in the lowest layers, and thus cause sufficient bending of the direct rays to account for the received signal and its variations. As mentioned above, rapid fading occurred mainly on the wave-length of 5 m. and was usually superposed on flat or steady records and was present only in winter. It is thought that this is probably a shimmering effect due to turbulence in the atmosphere during bad weather. A similar effect had previously been noted by Ross Hull in the United States and was attributed to the same cause.

A more detailed study of the radio phenomena on the above lines has not been possible on account of the limitations imposed by the nature of the meteorological information available at the place and for the period of the wireless observations. In future investigations, this limitation may be at least partly removed, by improved meteorological technique for studying conditions in the lower atmosphere, and by making arrangements for special and close co-operation between those responsible for the wireless and meteorological observations.

FORTHCOMING EVENTS

Monday, January 4—Wednesday, January 6

AGRICULTURAL EDUCATION ASSOCIATION (at the Midland Agricultural College, Sutton Bonington, Loughborough). Conference.

Monday, January 4

SOCIETY OF CHEMICAL INDUSTRY (FOOD GROUP, PLASTICS GROUP AND LONDON SECTION) (in the Royal Institution, Albemarle Street, London, W.1), at 2.30 p.m.—Prof. E. K. Rideal, F.R.S.: "Catalytic Hydrogenation" (Jubilee Memorial Lecture).

Friday, January 8

INSTITUTION OF MECHANICAL ENGINEERS (at Storey's Gate, St. James's Park, London, S.W.1), at 5.30 p.m.—Mr. C. C. Pounder: "Some Types of Propelling Machinery available to Shipowners" (Thomas Lowe Gray Lecture).

NORTH-EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (at the Mining Institute, Newcastle-upon-Tyne), at 6 p.m.—Mr. C. Le Maistre: "War-Time Standardization".

Saturday, January 9

ASSOCIATION OF SCIENTIFIC WORKERS (in the Lecture Theatre o the London School of Hygiene, Keppel Street, London, W.C.1), a 2.15 p.m.—Conference on Problems connected with the Organisatio Application and Personnel of the Medical Sciences. (Chairman: D D. McClean.)

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or be fore the dates mentioned:

LECTURER IN MECHANICAL ENGINEERING—The Principal, Heriot Watt College, Edinburgh (January 7).

ASSISTANT TO THE ADVISORY OFFICER IN ANIMAL HUSBANDRY—The Secretary, West of Scotland Agricultural College, 6 Blythswoo Square, Glasgow (January 8).

WOMAN PSYCHOLOGIST for service at the Child Guidance Clinic—The Chief Education Officer, Education Office, Council House, Margare Street, Birmingham 3 (January 9).

REGIUS PROFESSOR OF GEOLOGY at Edinburgh University—Th Private Secretary, Scottish Office, Fielden House, 10 Great Colleg Street, London, S.W.1 (January 11).

SCIENCE GRADUATE (BOTANY), with experience in abstracting an knowledge of languages desirable—The Deputy Director, Imperia Bureau of Plant Breeding and Genetics, Cambridge (January 16).

RUSSIAN TRANSLATOR to work on literature in Agricultural Botan —The Deputy Director, Imperial Bureau of Plant Breeding an Genetics, Cambridge (January 16).

HONOURS GRADUATE TO TEACH BIOLOGY in the Bede Collegiat Girls' School—The Director of Education, 15 John Street, Sunderlan (January 18).

LABORATORY STEWARD for the Veterinary Laboratory—Th Veterinary Investigation Officer, University College of North Wale Bangor (January 18).

THREE JUNIOR ELECTRICAL INSPECTORS OF MINES—The Ministr of Labour and National Service, Central (Technical and Scientific Register (Section D.521), Sardinia Street, Kingsway, London, W.C.

RECONSTRUCTION AND SOCIAL SECURITY

THE full significance of the Beveridge report is only becoming apparent as its place in general reconstruction policies is appreciated. Already the report has brought the phrase 'freedom from want' out of the abstract into the concrete, and in doing so, as an article in the American periodical *Fortune* shows, makes a contribution to Anglo-American solidarity that should not be underrated. "We believe that it is possible, and therefore desirable, for the Government to set a minimum below which employment and the national income will not be permitted to fall. . . . Such a policy would in effect guarantee the existence of a job for every man who wants and is able to work. We do not think that the American voter will settle for less, and we see no reason why he should be asked to."

In the conditions or assumptions upon which Sir William Beveridge bases his Plan for Social Security, its linking with an all-embracing public health service and a national and international policy to maintain employment, he is clearly in line with tendencies in the United States which were foreshadowed in President Roosevelt's speech on "The Four Freedoms" two years ago, as the reception of the Plan outside Great Britain testifies. Already the report has put into our hands a weapon for political warfare of the first importance, when once the Government has recognized the opportunity and matched it with a series of social measures such as would restore the faith of the ordinary man throughout the world in the power of democracy to answer the imperious needs of a new age.

The exigencies of the war situation are therefore a reason not for delay but for action on the report. Sir William Beveridge, in the closing passage of his report, urges the importance of his proposals, or other proposals covering the same ground, as an aid to victory. His prescience has been brilliantly vindicated by the reception of the report abroad, the universal recognition of the connexion between the Beveridge Plan and the Atlantic Charter, and the acceptance of the report as a concrete effort to apply our principles and give a lead in building a world for the greater happiness of the ordinary man. There may be modification in detail, but there can now be no casting aside of the report without breaking faith. Action is imperative, and while it is right that there should be full deliberation over the proposals, procrastination would be a peril to the common cause as well as to ourselves.

Emphatically the first need is for decision as to the acceptance of the principles involved. This is the first step to be taken, before the detail of preparing the necessary legislation and bringing the scheme into being ready for the end of the War can be undertaken by some person or body appointed for that purpose. Decisions as to the rates of benefit and contribution can be left until the probable level of prices after the War is better known.

What is true in this question of the prevention of want is no less true of other aspects of reconstruction.

The prevention of want and the prevention of idleness, as Sir William Beveridge emphasized in his lecture to the Fabian Society, are distinct problems, needing distinct solutions. None the less, they are related problems, and the Beveridge report has the further merit that it places the whole question of reconstruction in its right perspective and calls for action all along the line in the attack on the five giant evils of physical want; of disease, which often causes want and brings other troubles in its train; of ignorance, which no democracy can afford among its citizens; of squalor, which arises mainly through the haphazard distribution of industry and population; and of idleness, which destroys wealth and corrupts men. Statement of a reconstruction policy by a nation at war is statement of the uses to which that nation means to put victory, when victory is achieved. In a war which many nations must wage together as whole-hearted allies, if they are to win victory, such a statement of the uses of victory may be vital.

Sir William Jowitt's speech, like that of Mr. Eden, in the recent two-day debate in the House of Commons on reconstruction, afforded some further evidence that the Government has fully in mind the wide range of problems involved, but the debate was chiefly of interest for its indication of a general sense that it is high time for general discussion to crystallize in terms of policy. Mr. Attlee has since affirmed the Government's resolve not to return to a scarcity economy, but to base policy on the utilization of abundance, and, in particular, has pledged the Government to an attack on the four great problems of unemployment, housing, social security and education, in the last of which, he said, investigations have reached an advanced stage. What is required, however, is decision on questions that determine policy. Of some of the vast territories on the map of the future which Sir William Jowitt and Mr. Eden endeavoured to unfold in response to Mr. Greenwood's appeal, a few, like those covered by the Barlow, the Beveridge, the Scott and the Uthwatt reports, have been fully explored. Others are now being explored by committees more or less well qualified and more or less adequately equipped. The recommendation of the Beveridge report for a further immediate investigation of the finance and organization of medical services with a view to the establishment of a comprehensive health and rehabilitation service is an example of other fields as yet marked out only in the broadest outline. The urgent need everywhere is to press forward the work of inquiry and, where this has been completed, for the Government to take clear and authoritative decisions of policy.

It is at this point that the Government's inaction is disquieting. The announcement of a new Ministry of Town and Country Planning is a decision to create machinery, not a decision of policy, and ill conceals a reluctance to reach a decision on the most important recommendations of the Uthwatt and the Scott Committees and the Barlow Commission. Again, there is a hesitant note about recent pronouncements on education, which the decision practically to suspend arts courses in the universities of Great Britain will emphasize. Further, the Beveridge report removes the last reason for delaying a decision on family allowances.

First among the decisions of principle now or soon required from the Government are clearly those on physical reconstruction and development of rural and urban Britain, on the integration of social services, and on education. In regard to these, it may well be argued as further reason for urgency that, though there may be division of opinion as to method, there can be little as to objectives. There is vital work to be done on which there is no controversy on Party lines. Whole towns, for example, must be reconstructed because the enemy has left no option, civic life has to be restored and strengthened, and the mobilization of peaceful industry to be achieved with the demobilization of the defence forces and war industries. These are obligations laid upon us by the impact of war, and they will summon for their discharge a spirit of public service which is the pride of all Parties and the monopoly of none.

The failure to implement sound planning on the lines lucidly and cogently recommended by impartial experts of unimpeachable qualifications, as in the Uthwatt report, or to allow them to be whittled down by the mere fear of action on a scale commensurate with the need, is to miss a great opportunity. Every social advance entails, and always has entailed, an adjustment of private interests to the requirements of public interest.

The interdependence of domestic and external policies, though it must be kept carefully in mind, for freedom from want cannot be achieved in isolation, either from attack on the other problems emphasized by Sir William Beveridge, or from other nations, must not be an excuse for procrastination or indecision. A world economic survey in this field would assuredly yield valuable results in the assessment both of want and of available supplies, a matter in which the Allied Post-War Requirements Bureau is only covering a part of the field. There need, however, be no delay in taking the decisions on policy and the establishment of the machinery and the preparation of legislation while the final facts determining the level of need and contribution are being ascertained.

There can be no doubt as to the value of general confidence that the Government had effective plans for maintaining employment after the War, and would use all the powers of the State, so far as necessary, for that purpose. That confidence, as Sir William Beveridge rightly insists, would be in itself a major contribution to victory, and nothing could more surely engender that confidence than the demonstration in those fields where the exploratory work is complete that the Government is ready and determined to act. As Mr. Greenwood rightly observed, it is the Government's business to lead and to make proposals for the future which honourably fulfil, so far as within its power, the promises that have been made. There can be no sheltering behind a smoke-screen of non-controversy. The test must be, not whether proposals or policy are controversial, but whether they are necessary and desirable in the national interest.

It is true that there must be frank and balanced recognition of all the elements demanded in a collective national effort. The Social Security Plan, for example, may have repercussions on our export trade which must be considered, as was frankly recognized by Sir William in his notable address before the Fabian Society. Maintenance of employment, upon which the success of a social security scheme depends, is the most urgent, important and difficult of reconstruction problems. Methods of solving it must be agreed and settled during the War. The demobilization plans of the Government must include not merely dealing with the armed forces and converting the war industries to peace production, but also a great development of export trade to pay for the food and raw materials which used to come as payment of interest on our overseas investments and for our shipping services. National planning and direction in the use of our resources are also essential. Both capital and labour, as Sir William Jowitt emphasized, must be more fluid, and barriers of custom, trade union rights and property rights which hinder the use of national resources in the way most urgently needed must be abolished.

In the execution of the plan it will be vital to preserve initiative and enterprise. The practical problem is that of discovering how to combine the proved benefits of private enterprise at private risk in the past with the necessity of national planning in the aftermath of War. That problem can only be solved by thorough and impartial investigation, and we may well hope that it will not be neglected by the committee appointed to formulate detailed proposals on the organization of industry to which reference is made in the recent statement; "A National Policy for Industry". Moreover, any further extension of Government activity in the economic field clearly involves reconsideration of the machinery and methods of government, including both the central organization and the Civil Service. We must face the possibility that for new jobs we may require a new type of official and a new organization. Sir George Schuster suggested in the reconstruction debate that we may need to develop a new career of what might be termed industrial statesmanship. There are already great industrial organizations which provide places for men of this type, but men of like calibre and experience are required on the Government side, who understand industrial processes and trade and yet are in a position to see the tasks and problems from the point of view of the Government as representing the whole community. Sir William Beveridge's own suggestion was for an Economic General Staff.

The question of the democratic institutions by which the organizing power of the Government can be integrated with the driving force of individual enterprise is one of the fundamental problems that confront us, and none makes more searching demands on lucid and intrepid thinking. There can be no quarrel with Sir William Jowitt's statement that the Government is surveying industry by industry because the structure of industry will not fit into a common mould. Different methods of co-operation and control may well be developed for different industries, but while the exact methods by which Government control and planning are to be exercised for particular situations require investigation and consideration, it is imperative that there should proceed simultaneously on the Government side an overhaul of the whole machinery of Government, including not merely the structure, recruitment and adequacy of the Civil Service as an instrument of modern government, but also of the ministerial and cabinet responsibilities and relations which are involved.

Those wider and fundamental considerations, rather than departmental interests or sectional views, should determine the choice of the machinery to be used in planning; between, for example, the recommendations of the Barlow Commission and the Scott and Uthwatt Committees. That is the least satisfactory feature of Sir William Jowitt's announcement of the establishment of a Minister of Town and Country Planning. Such a Ministry may, it is true, develop ultimately into the wider Ministry required to ensure full co-ordination and the formulation and execution of an adequate national policy. There is, however, nothing to indicate that the decision is based on a full examination of the structure of the Government machine, rather than on a desire to gain time and meet an embarrassing demand for action, as the successive changes of policy in this matter of planning might suggest.

It is well that there should be no hasty steps which might prejudice the establishment of machinery and institutions best adapted to serve the needs of the whole nation, and to reconcile the virtues of freedom and initiative with the order and discipline inevitable in a measure of planning. There must be timing in our planning: education is only one sphere where this is all-important. Democracy cannot seize the full opportunities which the War has opened up without fundamental and constructive thinking on these issues. Meanwhile, however, there is plenty of room for action to secure the ground required for further advance, to prevent obstruction by sectional interests and privileges, and to work out the technical and administrative details of the measures required to give effect to a national policy aimed at securing freedom from want and from unemployment, a programme for health and education, and the elimination of the squalor which arises through haphazard distribution of industry and population or the waste and abuse of resources or amenities. Wide though the range of Sir William Jowitt's survey, welcome as may be his remarks on housing, welfare and nutrition, agriculture, forestry, water supply, electric power supply and education, he said little to indicate that the Government has reached the stage of decision and action. Words alone will no longer satisfy the country as to the Government's earnestness in the matter, or fulfil the hopes and expectations which the Beveridge report and the speeches of Government spokesmen both in Great Britain and in the United States have already aroused. There can now be no turning back. The Beveridge Plan is not the only one which points to courageous simplification with great savings in administrative costs and in efficiency at the centre. From scientific workers as from other members of the community comes the demand that the Government shall match both the opportunity and its own declarations with decisions and administrative and legislative acts worthy of the cause in which we contend. They would be as inspiring to the nation in its war effort as the implementing of a social security policy would assuredly be in giving strength and a renewed impetus to the cause of the United Nations.

NORTH-WEST AFRICAN PREHISTORY

The Prehistoric Archæology of North-West Africa
By Frederick R. Wulsin. (Papers of the Peabody Museum of American Archæology and Ethnology, Harvard University.) Pp. xii + 173 + 12 plates. (Cambridge, Mass.: Peabody Museum, 1942.) 3 dollars.

THIS is a book some of us have been wanting for a long time. From the prehistorian's point of view, north-west Africa is an extremely interesting region, and until now information about it could only be obtained in 'bits and pieces', often in articles which were difficult to come by. It is true that the author does not pretend to have visited the area he deals with, still less to give the results of his own excavations in the field; but he has examined most of the available literature critically, and as a result has pieced together a consistent account of the whole subject. A certain school of thought has grown up recently which appears to consider that no publication can be of much worth which does not give the results of personal excavations and investigation in the field. Those who take this view perhaps forget that their own results will necessarily have to be utilized by future researchers in the same way as Mr. Wulsin has used his sources, and their findings similarly subjected to critical study.

That the final conclusions given in this book will be universally accepted in their entirety is, of course, unlikely—indeed there are a number of alterations which will probably have to be made—but none the less the whole collects together conveniently a mass of information and will form the basis for all future discussion on the prehistory of this area.

The opening chapter sets the stage for the ensuing work from its environmental point of view. The area is defined and the climate, both present and prehistoric, considered; and it is interesting to note that apparently there has been little climatic change since Roman times. There follows a chapter on the Lower Palæolithic sequence. Here the author seems to accept the possibility that some of the *coup de poing* industries found on the surface in this area could be of much later date than their equivalents in western Europe (p. 13). But surely it is not so much the similarity in the shape of tools, ranging from South Africa to western Europe, that matters, impressive as is this fact alone; the point is the similarity in the evolution of the industries in these far-flung areas. Yet such an evolution took place under diverse conditions, and different materials were used for fashioning the tools. Surely this similarity in the evolution of the industries argues for more or less of similarity in date. Should there have been any great time lag, the different conditions in the different areas would have given rise to different developments. Indeed it would seem to me that there must actually have been slow cultural interpenetrations—like the movements of molecules in a liquid—which helped to give rise to the uniform developments that we find.

The relationship between the Lower Palæolithic industries and the geological changes as shown by strand lines is next considered. Here the author accepts Vaufrey's conclusion that no pleistocene bridge existed across the Mediterranean. If this were really so, north-west Africa would certainly have been, as suggested, rather a backwater than a highway—though none the less interesting for that—and communication between Africa and Europe would, until later times, have been almost entirely through Syria. One ventures to wonder whether this question is quite certainly settled. The author's tentative dating of the Chellean to a Mindel-Riss interglacial phase is, I think, probably incorrect. The industry at El Hank on subsequent investigation appears to be mixed Chelleo-Acheulean, and it would surely seem more likely that the true Chellean is contemporary with the final stages of the 90 m. shore-line and thus Gunz-Mindel in age—a correlation which agrees with the results of investigations in the Somme valley.

In his chapter on industries and their variants, the author deals with the middle stone age which, as always in Africa, is difficult to pin down and presents a number of variations. I wonder whether it is wise to use the term Mousterian until it has been definitely proved that Neanderthal man lived in the region and made these industries? But this question involves a definition of the term Mousterian. Mr. Wulsin uncompromisingly classes the Aterian as a Mousterian with one new tool, the tanged point. Actually tanged points have been found in Mousterian levels both in Jersey and at La Ferrassie. But surely the true Aterian is more than that. Among other types occurring, what about the points with thinning flaking on their under surfaces? That the Aterian has middle stone age traditions is undoubted, but can one not see later stone age contacts present? Its date, anyway, would seem to be late middle stone age. A chapter on the Upper Palæolithic follows next. Here a distinction is made between the Capsian culture and the Oranian culture, which has a rather different distribution. Both develop into Neolithic industries. One of the troubles in this southern region is the lack of the distinctive and drastic climate changes which give rise farther north to clear-cut distinctions between the various cultures. In Africa a culture, and the fauna too, just tend to continue on and merge into the succeeding culture, even when this latter is really mainly due to migration from outside the region and not to simple evolution of the predecessor.

Mr. Wulsin, naturally, does not discuss the problem as to whether there is any cultural connexion to be seen between the early Upper Palæolithic of north-west Africa and the Perigordian of western France; this would have made an intriguing digression. In passing, one can note a misprint on p. 81, where the word Caspian appears instead of Capsian in the table. Chapters on the Neolithic and early historic periods follow. There is still, of course, much work to be done on the desert pottery. It is unfortunate that many of the results obtained by the Wellcome and the Mond investigators still remain to be published. A most interesting chapter (illustrated) on the rock-shelter art follows. The author seems to accept Vaufrey's view that the drawings are Neolithic. It would seem, however, probable that an earlier rock-shelter art existed in the region, and that some of the drawings belong to this earlier date and culture. The Grotte d'in-Ezzan lies outside the region under review, but the earliest paintings there do form a link between the earliest art in Southern Rhodesia and that of eastern Spain. The latter is certainly in part older than the Neolithic. Finally, there is an excellent résumé on the skeletal finds and a general conclusion. A useful appendix on the prehistoric mammals of Algeria is given, and an excellent bibliography concludes the work.

The whole volume is lucidly written and well got up and misprints are rare; indeed with the exception of the 'Caspian' for 'Capsian' already noted there are none which are immediately obvious. Mr. Wulsin has done an excellent piece of work which will notably lighten that of all future investigators of north-west African prehistory. M. C. BURKITT.

THE COUNTRYSIDE AS IT WAS

Country Ways

By Esther Meynell. Pp. v+152. (London: Chapman and Hall, Ltd., 1942.) 12*s*. 6*d*. net.

Field Fellowship

By H. J. Massingham. Pp. 192+16 plates. (London: Chapman and Hall, Ltd., 1942.) 8*s*. 6*d*. net.

ENGLAND was last swept by a wave of faith during the Victorian era. Men worshipped wholeheartedly at the shrine of progress and were so intent on their end that they scarcely had time to notice the means they were employing. Then came the great reaction against this boundless faith and optimism. Men could not help noticing the consequences of their work: the dark factory filled only with gloom, machinery and hands; the slums and the slag-heaps that littered the countryside; and the appalling intellectual poverty of the bulk of the population. The city dweller, seeking ways of overcoming these blots of civilization, looks forward to an era of light and airy factories and homes built of modern materials if need be, glass, modern alloys and brightly coloured plastics, with gas and electricity as sources of light, heat and power.

The literary country dweller tends to take the opposite view. Seeing the slum, the slag-heap, and the soulless factory, he longs for the time before these existed, the era of the medieval village, the wood fire and the village pump; the era in which change, if it came at all, came extremely slowly. Village life was hard but satisfying, devoid of doubt or change, where every good workman was a craftsman and extremely proud of his craftsmanship. There were no mere mechanical machine minders in those days nor any leisure for such passive occupations as cinema-going. These two books, in their different ways, both describe this way of life, both seeing the village through rose-tinted glasses.

Mrs. Meynell's book describes country life as it was, illustrating her story with well-chosen quotations from contemporary authors. She is unashamedly parochial—her countryside is Sussex—but the book gains in vividness by this rigid geographical limitation. She knows her authors well and quotes sympathetically from many hitherto neglected. It is one of the most charmingly written of country books, and will delight every lover of the countryside.

There are only a few statements to which exception can be taken on grounds of scientific accuracy. Her statement that "the principle of ploughing—which is the inversion of the soil—remains the same, however eagerly man seeks after many inventions" is certainly not valid in the semi-arid regions. The ploughs used in the Middle East, which probably antedate the European by several millennia, have no mouldboard and only break up the surface of the soil without inverting it. The cause of the dust bowls in America and elsewhere is in part due to the unfortunate use of the European instead of the Asiatic plough. It cannot be due, as she suggests, to the use of artificial fertilizers, which are not used there owing to lack of water.

Mr. Massingham's book is a collection of articles about various aspects of country life. The longest section gives an admirable account of village architecture, showing in detail how sensitive the village builder used to be to the inherent qualities of his local material, and how his buildings displayed these qualities. Then there is a very sympathetic essay on W. H. Hudson which does full justice to his memory.

In the remaining thirty-seven short articles Mr. Massingham is an unrepentant longer for the past. What seems to be wrong, he says, with English village life is that it has changed since the seventeenth and eighteenth centuries, and almost every change has been for the worse. He writes appreciatively and with knowledge about old customs and trades, and so scathingly about modern ones that he is not concerned too much with mere scientific accuracy. Thus he is very fond of wholemeal bread, and sees, to his dismay, that the inhabitants of his village eat, in peacetime, white bread baked from white flour that has been milled in a large roller-mill situated at a port. What easier than to accuse the big millers of encouraging people to want to eat white bread. Yet Drummond and Wilbraham pointed out in their book that people were clamouring for white bread a full century before the 'big business' miller and the roller mill. Parliament tried several times in the eighteenth century to make people buy a good nutritious standard loaf, but the clamour for white bread continued, though it was more expensive and the whiteness was often obtained by using alum and perhaps other adulterants.

The picture of the countryside to-morrow need not be so black as Mr. Massingham implies. Mechanization of agriculture means using machines to do work previously done by hand, but it does not necessarily mean cultivating 1,000 acres with 100 horse-power tractors. To-day the corn ranch can be mechanized, and there is no reason why a mixed dairy farm of 100 acres and small fields may not be as completely mechanized in the future, though the dairy herd could, and probably would, receive as much personal care as in the past.

Mr. Massingham naturally deplores the loss of ancient crafts in the villages that followed the introduction of the factory, but he seems to have overlooked the new crafts now being acquired. The village garage mechanic is often a superb craftsman, but he uses steel, the oxy-acetylene torch and the power-driven lathe instead of iron and the treadle lathe of his ancestors. But that makes him none the less as genuine a craftsman as the village carpenter, though his workshop may smell of oil rather than of wood shavings.

These two books serve the valuable purpose of emphasizing that village life had an unhurried simplicity and gave a contentment to its inhabitants that is frequently lacking at the present time. One of the great problems for the future is to fuse this essential completeness of village life with the intellectual ferment so characteristic of the present time. Few would willingly wish to retain the intellectual stagnation that was too often a characteristic of village life in the past.

E. W. RUSSELL.

FOUNDATIONS OF ASTRONOMY

Foundations of Astronomy

By Prof. W. M. Smart. Pp. vii+268. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1942.) 16*s.* net.

PROF. W. M. SMART needs no introduction as a writer of astronomical books. These range from popular accounts such as "The Sun, the Stars and the Universe" to his valuable and comprehensive work "Stellar Dynamics", dealing with the movements of the stars.

The work now under review falls in the gap between popular descriptions of astronomy and general text-books for university students, such as the standard "Text-book on Spherical Astronomy" by the same author, now in its second edition. "Foundations of Astronomy" is intended for students taking a first-year course in astronomy in the universities and for all those interested in the subject who feel the need for a more solid foundation than the many descriptive books can provide. The author hopes also that the book will be of value to the many young men in the naval and air forces, who are required to have some knowledge of astronomy in its application to navigation as an introduction to the Service manuals in which greater emphasis is laid on technical matters.

Commencing with chapters on "The Geometry of the Sphere" and "The Celestial Sphere", the book gives definitions of most of the astronomical terms, accompanied by full and careful explanations, which will be found simple to follow, and by illustrative examples. A prominent feature in these explanations is the use of appropriate diagrams, well thought out and produced. Along with these definitions there occur many descriptions and explanations of natural phenomena which will be found illuminating. It is worth noting that the spherical trigonometry used is made to depend on one formula only—the cosine formula—and that this dependence is direct in each case.

Although the astronomy is mainly positional, the chapter on "The Stars" includes a brief introduction to the spectrum and to some of the important and fascinating results which may be obtained by studying the constitution of the light from the stars. A chapter on the "Determination of Position on the Earth" is also included.

A useful feature is the inclusion of a number of examples for the student at the end of nearly every chapter, together with a collection of answers at the end of the book. Appendixes give tables of astronomical constants and the elements of the planets and the satellites, and the book possesses a useful index.

The work is beautifully printed and shows very little evidence of war-time production.

A few minor misprints and obscurities have been noted, but only one seems likely to cause confusion; in section 138, on the "Heights of Lunar Mountains", it should be noted that only a particular case is concerned, when M is on, or very near, the moon's equator (incidentally, Y is not a cusp).

"Foundations of Astronomy" as a whole gives a simple and adequate account of astronomical terms and usage; further, it is at the same time just a little more than a bare text-book in that it describes rather more phenomena than are needed to explain the definitions. The mathematical attainments of the student are carefully considered, as is indicated by the use of asterisks to point out sections which may be omitted from a first reading, and by the very careful explanations, particularly in the more elementary parts—the true "Foundations".

J. C. P. MILLER.

DRAINAGE OF OIL WELLS

Oil Well Drainage

By Dr. Stanley C. Herold. Pp. xv+407. (Stanford University, Calif.: Stanford University Press; London: Oxford University Press, 1942.) 30*s.* net.

PETROLEUM technologists, especially on the production side, will be familiar with the author's "Analytical Principles of the Production of Oil, Gas and Water from Wells", published in 1928—a severely mathematical treatise of a complex subject. Reviewing that volume the writer stated at the time that it was "unquestionably a remarkable effort for one man and nothing quite like it has appeared before in the annals of petroleum literature". The same can be said of this, Dr. Herold's latest work. This time it is the story of oil well drainage shorn of mathematics (except in a brief appendix) but replete with recorded incidents and observations skilfully interpreted in terms of what is unseen in natural oil reservoirs. The basis of this work is primary analysis of any particular North American oilfield by reference to a questionnaire of twenty-one questions (introduction) to which appropriate answers, where they can be given, are collated and resulting data segregated according to whether the oilfield is Palæozoic or Cenozoic.

This division into "older" and "younger" constitutes a twofold classification governing considerations of reservoir energy; the function of natural gas; radius and area of drainage; regional drainage and water encroachment; drainage across property lines; effects of stratigraphy and structure on drainage; effects of reservoir penetration on drainage; effects of multiple zones on drainage; effects of rates of production on drainage; effects of field development on drainage; drainage by wells of all or no gas; injection of gas, water or oil; reservoir content, ultimate recovery and reserves; abandoned oil and gas; curtailment, proration and conservation.

There are always snags in any attempt at simplification of highly variable functions, especially of fluids like petroleum and natural gas. For example, oil wells drawing from Tertiary deposits may simulate Carboniferous or older formational types of production and *vice versa*. The admittedly rarer instances of Mesozoic oil may possess production characteristics of either Cenozoic or Palæozoic pools; the author apparently sees no reason to suspect a third type of production peculiar to Mesozoic formations, but he does not neglect such possibilities. Another interesting point: two types of production provide two types of drainage and, according to the author, where an oil well at any specified time of its life is producing exclusively to the pattern of one type of production, its reservoir is subject to only one corresponding type of drainage and there is no compromise between the two types. But conditions may alter within the reservoir when the well may change its production and drainage pattern from one type to the other.

This is admitted, but surely it does complicate the issue considerably; whether such change can always be detected from performance of the well or behaviour of reservoir, as suggested by the author, is a debatable point, especially, for example, in the case of production from multiple sand lenses embedded in clay, for example, Trinidad.

Although this book deals essentially with the physical features of production and drainage, the mathematical basis or proof for the theses submitted is constantly in the background and one feels that the period 1928–1941 has, by increased experience in many fields, served rather to confirm than to amend the author's earlier analytical results. In fact, in a delightful preface, he acknowledges James Perrin Smith's advice to him to tell the story "in simple language and do not fail to cite the field examples of drainage that you will have found". This has been done and done well, in a volume of some four hundred pages, thirty-six line diagrams of oil fields and relevant subjects heading the chapters, and in an easy, informal, conversational style that in no way detracts from the masterly grip Dr. Herold obviously has of a subject he has made very much his own.

Whether the profusion of small-type marginal notes throughout the text, plus the use of several different point sizes, including Gothic type captions, is intended as an artistic presentation of a subject that has few of the arts and most of the sciences, is doubtful and, in these days of austerity printing, the reader may think this has been rather overdone. But no one, not even "the operators, leaseholders, landowners, attorneys at law, legal experts on contracts, politicians and governmental agents", for whom the story is told in this way, can fail to derive a measure of contentment from its unfolding; to that list may well be added the "petroleum technologist", to whatever specialized branch he devotes his ability and learning.

H. B. Milner.

NON-SINGULAR CUBIC SURFACES

The Non-Singular Cubic Surfaces

A New Method of Investigation with Special Reference to Questions of Reality. By B. Segre. Pp. xi+180. (Oxford: Clarendon Press; London: Oxford University Press, 1942.) 15*s*. net.

This is a very remarkable monograph; it is a direct product of war circumstances. After a curt verification of the existence (Cayley, Salmon, 1849) of a symmetrical system of twenty-seven lines, each met by five pairs of mutually intersecting lines, the author turns to a diagrammatic representation of the lines, by the joining segments of nine points which lie in threes on three coplanar concurrent lines. This is reached by considering how the lines would vary in a continuous deformation of the surface into three planes, and, beautifully executed as they are, the various diagrams serve the author's purpose well. Actually, the representation is the dual of one considered by Bennett, in which the lines of the surface are represented by the points in which the rays of three coplanar pencils, α, β, γ, each of three rays, meet one another; in this representation a line of the (Steiner) system of nine lines, represented by the intersection of a ray b of the pencil β, with a ray c of the pencil γ, meets the four lines indicated by the intersections of the other rays of these two pencils, and meets the six lines indicated by the intersections of b and c with the rays of the pencil α. This law of intersection is unaltered by the interchange of the rays of a pencil among themselves, or by the interchange of the pencils.

It can be shown that there are forty ways of arranging the twenty-seven lines in such three associated Steiner systems, indicated by the intersections of three pencils of three rays. Thus there are 40×6^4, or 51,840, ways of arranging the twenty-seven lines among themselves so that all intersections persist. The *group* of operations which effect these arrangements is also obtained by the author by combining the thirty-six transpositions of the lines of the various double sixes; his discussion involves a masterly exposition of the relations among the lines. He shows, too, as Burnside had shown, that the group can be generated by combining only six such transpositions. He does not refer to Coxeter's conclusion that the group can be generated by combining one such transposition with a single cyclical change of nine tritangent planes, containing the lines of three associated Steiner systems.

In pursuance of his main object, the author next obtains the five Schläfli types of real surfaces, $F_1, \ldots, F_5$, with, respectively, 27, 15, 7, 3, 3 real lines (the last type consisting of two pieces). However, to study the groups of possible interchanges of the lines of these various types, many distinctions of character are considered for the lines. A real line is elliptic or hyperbolic, according as the involution on the line, arising from the tangent planes through it, has imaginary or real foci; and hyperbolic lines are of two kinds. An elliptic line is right- or left-handed according to the direction of rotation of the tangent plane through it, as the point of contact moves along the line. An imaginary line is (in von Staudt's phrase) of the first or second kind. All these, and other distinctions, must be preserved in the allowed exchanges of the real and complex lines of the surface, the aggregate of which constitutes the group. The result of a complicated discussion is that the respective orders of the groups of the real surfaces are 60, 36, 4, 24, 24.

After this the author proceeds to the consideration of the regions into which the real lines divide the surface. He computes, with an interesting examination of the shapes of the various regions, the number $r = 2 - \alpha_0 + \alpha_1 - \alpha_2$, wherein α_0 is the number of intersections, or corners, of the regions, α_1 is the number of segments, each terminated by two corners, and α_2 the number of regions; and finds the values of r for the respective types of real surfaces to be 7, 5, 3, 1, 1. A remark is possible in regard to these numbers: For the surfaces F_1, F_2, F_3, there exist double sixes of which one half consists, respectively, (1) of six real lines, (2) of four real lines and two conjugate complex lines, (3) of two real lines and two pairs of conjugate complex lines. If we compute the number r for a (projective) plane, using the joining lines of 6 (or 4, or 2) real points therein to determine the regions (with two other lines in the last case) we obtain $r=1$. But, if we make holes in the plane, bounded, say, by circles the centres of which are at the 6 (or 4, or 2) points considered, the values of r for the desiccated plane will be 7 (or 5, or 3). The suggestion of Cremona's representation of the cubic surface on a plane is obvious.

The last chapter of the volume, largely algebraical, is devoted to Sylvester's representation of the equation of the surface by the cubes of five linear functions. It is shown that there are two types only, of non-singular surfaces, which cannot be thus given by five (or fewer) cubes, but that these are given by six cubes. One type, with vanishing discriminant, requires seven cubes. The author also applies Sylvester's form to obtain the five types of real surfaces, distinguishing between them by inequalities among the coefficients multiplying the five cubes.

It will be seen from this skeleton survey that the book is one for which, for long years, the reader will be grateful to the author—and to the Clarendon Press. H. F. BAKER.

HIGH-SPEED COMPRESSION-IGNITION ENGINES

High-Speed Diesel Engines

With Special Reference to Automobile and Aircraft Types; an Elementary Textbook for Engineers, Students and Operators. By Arthur W. Judge. Fourth edition, revised and enlarged. Pp. vii+536+45 plates. (London: Chapman and Hall, Ltd., 1941.) 25*s*. net.

THAT a fourth edition of this book has been published only eight years after its first appearance shows that it meets a demand. The author has compiled a vast and valuable fund of information and has been very well supported in the presentation of this matter by the publishers. The greater is the regret that the author has not found it possible to reduce the number of errors and to avoid presenting, as in many instances, incorrect pictures of various aspects of his subject. To assist the student—and also the author in preparing a new edition—the following points are mentioned.

In the development of high-speed compression-ignition engines, extending over nearly twenty years, it is inevitable that many designs of combustion chamber and of injection equipment should be put forward and for various reasons afterwards dropped. In his preface, the author explains that he has retained many of these "in view of their historical interest". This would be well justified if he had indicated those designs that are obsolete and those which continue to be built; but the reader is left in complete ignorance on this distinction.

A similar vagueness surrounds many of the technical and experimental subjects treated by the author. Views of writers of scientific papers are often quoted or embodied in the text, the references and dates of the papers being usually quoted; but the value of these would be greatly enhanced, and a more accurate presentation given, if the author, after suitable analysis, had stated which of these had proved, in the light of later evidence, to be incomplete.

Some of the errors relating to combustion chambers are as follows: on p. 140, the statement appears that the Lanova combustion chamber was produced by the inventor of the Acro combustion chamber "acting in co-operation with F. Lang". This is misleading, but is nevertheless true, since Lang was the inventor of *both* combustion chambers. On pp. 143 and 144, reference is made to the Omo and the Oberhänsli combustion chambers, and the latter is said "to resemble the Omo". They are one and the same, the designer being the Swiss engineer, Oberhänsli, while the company controlling the commercial development is the Omo A.G., of Zurich. The M.W.M. design on p. 120 is given as a modified type of Acro combustion chamber: while it is similar, it was the result of independent development. A modification was, however, actually made by the Saurer company to the Acro design, by giving a 'cross-stream' motion to the air. The author attributes this modification to a designer, "Kreuzstrom" by name.

Contrary views are often given without suitable analysis, following the method of compilation adopted by the author. For example, the picture of the initiation of combustion presented on p. 94 differs from that on pp. 99 and 100. In discussing the influence of injection advance on ignition lag, on pp. 101 and 102, the author, near the bottom of p. 101, reaches the conclusion, given in italics: "the ignition lag will therefore be greater as the injection is advanced". On p. 102, he goes on to give the results of tests by Dicksee which, with one design of combustion chamber, confirm this and, with another, contradict this conclusion. This is followed by the correct conclusion that the result also depends on the combustion chamber; but this is not given in italics by the author, and a reader taking a cursory glance at the passage would be completely misled. If, however, the author had analysed the subject and had correlated the results with Bird's work in Fig. 53, or better with Wolfer's later work at Cambridge with Bird, which is not mentioned, a correct picture would have resulted.

On pp. 179 and 181, the author refers to the excellent pioneer work of Taylor and Hawkes at Farnborough, reported in Taylor's paper in 1927, and writes, with italics: "Another interesting point observed was that *as the torque was reduced, so was the specific fuel consumption*". Although slow-running compression-ignition engines had revealed such characteristics near full-load, this may have been a striking result in 1927 for a high-speed unit, but the author himself, notably in Figs. 15, 33, 263 and 297, shows that this has long been recognized as the normal characteristic of compression-ignition engines. This is a typical fault of compilation.

Errors and slips in references are numerous, and the following may be mentioned: p. 69, 1926 p. 555 for 1932, p. 685; Figs. 40 and 44 are obviously from the same reference but are not acknowledged; p. 36, 1831 for 1932; p. 169, 1931–32 for 1934, while Fig. 124 is from this reference but not acknowledged. 'Junkers' is usually given as 'Junker'.

Many of these are minor matters to those who have read widely in the subject; but in a work described on the title page as an elementary text-book for engineers, students and operators, they become of vital importance. Reference to the numerous original papers is difficult for such readers, and the responsibility of the author is great. It is to be hoped, therefore, that in the fifth edition which will certainly be called for, the author will convert his work from being merely good to superlative. S. J. DAVIES.

AN INTERNATIONAL ANTI-LOCUST CAMPAIGN

By Dr. B. P. UVAROV

Anti-Locust Research Centre,
Imperial Institute of Entomology

As an outcome of a series of intensive investigations carried out during 1930–38 by entomologists of several nations on a common plan, practical schemes for the preventive control of the three species of African locusts were formulated[1]; but the outbreak of the War in 1939 made the postponement of schemes, which were of necessity international in character, apparently inevitable.

Efforts to save the situation, however, were continued and full credit is due to the respective Governments for establishing two of the three projected organizations, although on a necessarily restricted scale. The organization for the control of the Red locust (*Nomadacris septemfasciata*), with headquarters at Abercorn, Northern Rhodesia, came into existence in 1940 and is now a joint British-Belgian undertaking. Its field work is progressing, and regular patrolling of the outbreak areas has already been organized.

The original outbreak areas of the African Migratory locust (*Locusta migratoria migratorioides*) are on the middle Niger in the French Sudan. Since swarms of this locust, if allowed to spread, would overrun the greater part of the African continent, the organization for the prevention of its outbreaks was planned as a French one, but supported financially by all the countries concerned. The isolation of French West Africa made the fate of this plan very uncertain, and considerable anxiety was felt in other countries of Africa that a new outbreak of the Migratory locust might develop on the Niger unchecked. It was, therefore, welcome news to learn that a "Centre du surveillance antiacridien" has been established on the Niger, as a purely French organization, though its work is certain to benefit a number of other countries.

No details are available as to whether the organization is sufficiently strong and extensive to cope with any emergency; but in any event its existence means that the beginning of the outbreak will not pass unnoticed. In fact, reports have come through that some signs of renewed activity of the Migratory locust were observed last spring on the Niger, but that the first incipient swarms have been destroyed. In view of this news, an effective strengthening of the French organization would be in the direct interest of the whole of West Africa, Equatorial Africa, Belgian Congo and all East African countries from the Anglo-Egyptian Sudan down to Southern Rhodesia, Mozambique and Angola.

The third species, the Desert locust (*Schistocerca gregaria*), presents the greatest difficulty from the point of view of its preventive control. The western region of its invasions comprises the drier zones of West Africa, Morocco, Algeria and Tunisia, and the investigation of its outbreak areas in that region had not been completed when a new invasion commenced in 1940; at present the invasion is fully developed and requires measures for direct control of swarms on a large scale. The eastern region of the Desert locust extends from India, through Persia and Arabia into Eastern Africa and the Sudan. Some of the original outbreak areas here have been discovered, and an organization for their preventive control should have come into operation in 1939–40, but the proximity of the war zone made this impossible. As a result, the first swarms had a chance to develop unchecked, and at present the Middle East, India and East Africa are faced with the prospect of repeated invasions during the next two to three years. The production of food and fodder is of considerable importance to the Allied war effort, since local shortage would have to be replaced by importation, with consequent extra demands on shipping space. Hence an anti-locust campaign had to be organized throughout the threatened countries.

Studies on the seasonal migrations of the Desert locust, carried out by the Anti-Locust Research Centre during the last twelve years, have shown that the whole region from India to East Africa forms an interconnected migration area. Swarms bred during summer monsoon rains in India move in the autumn to southern Persia and Arabia; the latter country receives at the same time swarms bred during the summer monsoon in Africa. Some of the invaders breed in southern Persia and Arabia, and in the following spring swarms move to the borders of Soviet Middle Asia, into Iraq, Transjordan, Palestine, Syria, Sinai and Egypt, where a spring generation is produced; later in the season there is a dispersal of swarms westwards to East Africa and eastwards to India for subsequent breeding in the summer monsoon rains.

The existence of such extensive movements of swarms makes it futile for each country to attempt its own isolated control operations, as has been the practice in the past, when a united anti-locust policy had little chance against the isolationist tendencies. Paradoxically, war conditions have removed many difficulties and have made it possible to organize, not a dozen small campaigns aimed merely at the defence of crops in each country, but the development of a single plan embracing all the countries involved and assuming the character of offensive operations. The plan aims at the extermination of locust swarms not only where they represent an immediate danger, but also in the desert areas where they may be harmless locally but represent a potential threat to other countries.

A campaign of this kind should be based on exact and timely information with regard to the movements of swarms, and special efforts have been made to improve and enlarge the existing locust information service. The present conditions have made possible its extension to areas which used to be inaccessible, so that now the developments in the whole region can be fitted into a single picture on which forecasts of expected movements can be based. It is a point worth mentioning that, during the present locust outbreak, no country has been invaded without receiving a timely warning from the Anti-Locust Research Centre, whereas in the past the invasions happened unexpectedly and defence measures had to be improvised in haste, with disastrous consequences.

In planning the campaign it was necessary, first of all, to take into account that in several of the countries concerned there exist efficient local entomological organizations. Such organizations in Egypt, Palestine, the Sudan and Kenya have undertaken to act as local centres for collecting information, while they also render great services to all surrounding countries by the preparation of poison bait and by the training of native technical personnel. The Anglo-Egyptian Sudan, with its model anti-locust organization, has naturally become a most important base and a training ground, not only for the technical staff who are sent to the 'locust control school' from other countries, but also for the newly appointed locust entomologists.

The second group of countries comprised those with anti-locust organizations of their own, but with resources insufficient for large-scale operations. War conditions have made it difficult to obtain, for example, poison for baits, and supplies had to be acquired in bulk and distributed where they were needed, while reserve stocks were laid down at conveniently situated bases. In the case of Persia, outside assistance with regard to supplies, however, did not solve the difficulty. Southern Persia was expected to become this winter an important, probably even the main, concentration area of swarms, and this forecast is being fulfilled. The local Persian entomological organization would be adequate in a normal year, but it was clearly impossible to expect it to deal unaided with the present emergency. Moreover, the immediate importance of locusts in the sparsely populated and little cultivated areas of southern Persia is much less than their threat to India, Soviet Middle Asia and the whole of the Middle East where they may spread next spring. On the other hand, such concentrations of swarms throughout the winter and subsequent breeding in early spring make southern Persia a convenient ground for large-scale operations designed to reduce the number of swarms available for invasions. These considerations led to the organization of a joint campaign in which Persian, British, Soviet and Indian experts are working side by side according to a single plan and pooling their resources.

Finally, there are some countries where there exist no organizations capable of undertaking locust operations. To leave them out would mean creating sanctuaries for locusts where they would breed undisturbed and then move in vastly increased numbers to more fertile regions. In this respect, the vast peninsula of Arabia represents a problem in itself. It has been established that over-wintering of swarms and their breeding in early spring occur in Arabia on a large scale, but that in late spring practically the whole peninsula is evacuated by swarms which spread to the surrounding countries, including eastern Africa. From the local point of view, locusts are scarcely of any economic importance, the population being largely nomadic, but the interests of other countries demanded the inclusion of Arabia in the general plan of campaign. The only part of the peninsula where operations could be organized by the local Government is Aden and its protectorates, where some assistance was needed only as regards supplies and technical personnel. Elsewhere, everything must be done by special motorized parties led by experts. Again, as in Persia, the collaboration of several countries has made this possible, and a plan has been prepared according to which several of the most suspected areas will be covered by the British, Egyptian and Indian parties. Very scanty information with regard to the interior of Arabia and obvious difficulties of work in such a country make this part of the campaign somewhat hazardous, but even if the immediate practical success is incomplete, valuable experience will be obtained for use in the next campaigns.

Ethiopia required special treatment. Owing to its geographical position it plays an important, but still very imperfectly understood, part in the seasonal migrations of locusts. Practically no data on this subject were available before the Italian occupation, and the short period of Italian rule coincided with the clear interval between the two outbreaks of the Desert locust. Therefore, it was essential, from the general point of view, both to ensure that the breeding of locusts and the movement of swarms in Ethiopia should not remain unknown, and to endeavour to introduce modern control methods into local use. A special anti-locust mission has been sent to Ethiopia, and its first aim is to create an efficient locust information service, as well as to demonstrate modern methods of control, and to train local technical personnel which may form the nucleus of an Ethiopian anti-locust organization. The work of the mission is proceeding with a considerable measure of success, and this large and important blank in the maps of locust movements in Eastern Africa is now being filled.

Such are the scope and the aims of the present anti-locust campaign in the Middle East and East Africa. Its general direction, requiring the close collaboration of many Government Departments, is in the hands of an Interdepartmental Committee on Locust Control at the Colonial Office, while the technical and the scientific side, including the planning of operations, is directed by the Anti-Locust Research Centre, under Sir Guy Marshall. The British experts who have been specially engaged for the liaison work between different countries and for directly conducting operations where this is required, form a Middle East Anti-Locust Unit, attached to the Middle East Supply Centre, which makes the necessary administrative arrangements for the provision of transport, the procuring of supplies, their distribution, etc.

With the campaign still in its initial stages, it may be too early to say whether the organization just outlined will prove to be adequate to meet the situation, which is certain to become increasingly serious. However, preparations have been made while the outbreak is only developing, and the first season should show whether any modifications are needed to meet the peak of the outbreak expected to be reached in 1943–44.

In these times, when the possibilities of planned application of scientific knowledge on a scale unrestricted by national considerations are attracting general attention, the present anti-locust campaign may constitute a useful test case. Four features of the campaign should be of general interest. First, the campaign has assumed its international scope quite naturally, because the situation could not have been dealt with efficiently on a narrow national basis. Secondly, the co-operation of the various countries concerned was obtained without difficulty, because their self-interests coincided with the common interest. Thirdly, the necessary unity of operations was achieved not by attempting to introduce a rigid central direction, which would inevitably cause friction, but by offering the co-operating countries a definite practical plan based on a sound scientific foundation. Finally, the whole organization is kept together by the demands of the work in hand rather than by formal agreements, and this makes it very flexible and easily adjusted to meet changing conditions.

---

[1] NATURE, 142, 174 (1938).

THE INTERFEROMETER IN LENS AND PRISM MANUFACTURE*

By F. TWYMAN, F.R.S.

THE optical system used by Michelson in his interferometer, which was applied by him to so many important purposes, has since 1917 been gradually coming into use in a modified form as a routine test in the manufacture of lenses and prisms. The various forms in which it has been used have been the subject of a series of patent applications[1] and have been described in various technical papers[2], which are of little interest except to specialists in optical manufacture. The general principles of the instrument may appeal to a wider circle and are sufficiently well illustrated by the two simplest forms called, respectively, the prism and the lens interferometer.

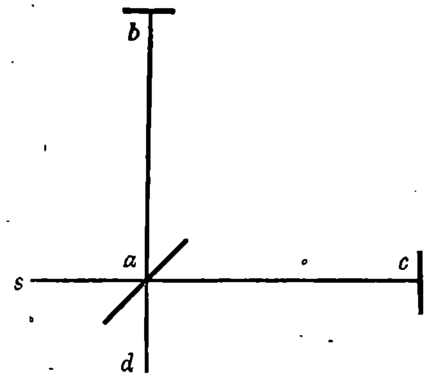

Fig. 1.

All the forms are based on the system of mirrors illustrated in the paper by Michelson and Morley (*Phil. Mag.*, 1887) and shown in Fig. 1. The effect of this system of mirrors is optically almost identical with the process of putting two flat glass plates together face to face to form Newton's colours. These are formed by interference of the light reflected from the two opposing surfaces, and are the same in their nature as the Newton's rings which are caused when a shallow convex glass surface is laid on a flat one. This ring system was described by Newton ("Opticks", Book 2), who was the first to find a relation between such colours and the corresponding distances apart of the surfaces.

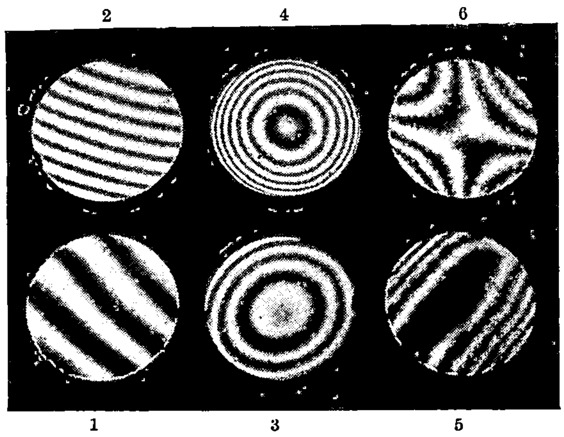

Fig. 2. APPEARANCES WITH PROOF PLATE.

1. Nearly perfect, the proof plate slightly tilted.
2. The same, but the proof plate tilted about 2½ times as much.
3. Astigmatic surface (slightly ellipsoidal).
4. Surface concave or convex, according to the colours.
5. Strongly astigmatic.
6. Astigmatic of the saddle-shaped variety, that is, concave in one direction, convex in the direction at right angles.

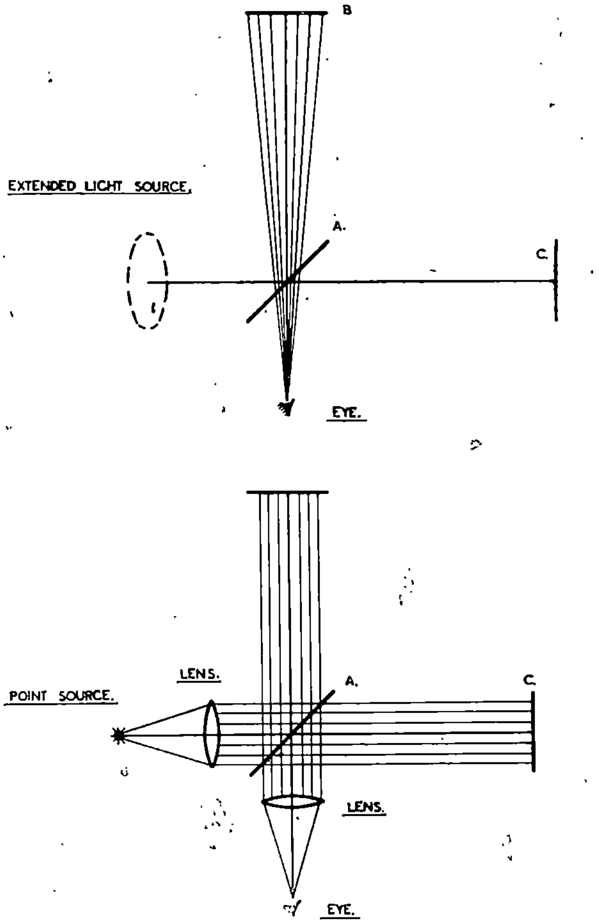

Fig. 3. DIAGRAMS OF MICHELSON (ABOVE) AND TWYMAN AND GREEN (LOWER) ARRANGEMENT.

Newton's bands have, of course, been utilized for many years, possibly for more than a century, in optical workshops, by the use of the optical proof plate. The optician has one surface which he calls the proof plate and on which he can rely as being of a standard flatness or sphericity, and he tests the flat or curved surfaces which he is making by putting the proof plate in contact with the work. Fig. 2 shows some of the appearances which may be observed.

Referring now to Fig. 1: *sa* is a ray of light which is partly reflected from *a* to *b* and partly transmitted from *a* to *c*, the mirror *a* being lightly silvered. If the paths *ab* and *ac* are equal, an image of *b* is formed in contact with *c*, and we have the conditions optically identical with those producing the Newton's colours when two plates are placed in contact. If the position of the mirror *b* is gradually altered we shall reproduce the optical effect of separating two such plates.

In the Twyman and Green prism and lens interferometers, the Michelson mirror arrangement is modified as shown in the lower part of Fig. 3. It will be seen that in the Michelson arrangement the

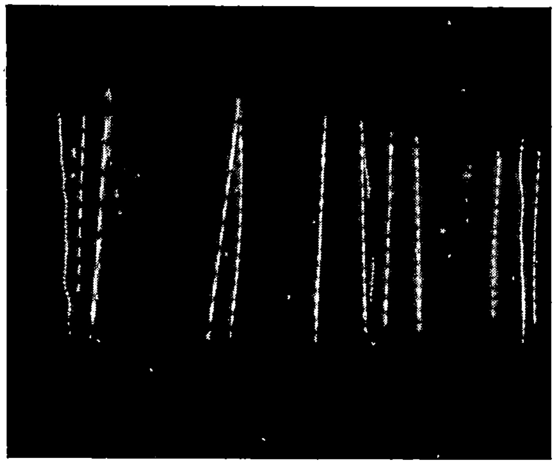

Fig. 4. FALL OF DUST PARTICLES.

rays which reach the eye come from the mirrors at various angles. An extended light source must be used otherwise only a small part of the field of view would be illuminated. If one of the plates is moved in a direction perpendicular to itself, one gets a system of rings exactly like the Newton's rings, which are seen when one separates two glass plates, while maintaining them parallel to one another and observing them at normal incidence. In the Twyman and Green arrangement of mirrors a point source is used and the spherical wave front proceeding from this is collimated to form an approximately plane wave front and so proceeds to the mirror system. On reaching the second lens it is once more converted into a spherical wave front converging upon the eye. The rays which reach the eye, therefore, have traversed the system parallel to each other, or to speak in the language of the wave theory of light, the beam of light traverses the mirror system with a plane wave front.

One part of the Michelson system has been omitted in these figures—a plate of glass of exactly the same thickness as that of the diagonal mirror. This is not necessary in the Twyman and Green instruments as used in the optical workshop, since monochromatic light is used, the light being obtained from a low-pressure mercury vapour lamp.

The simplest application of this instrument is to use it instead of a proof plate for testing the flatness of optical surfaces. To do this the mirror *c* is replaced by the object the polished surface of which it is desired to test; for that purpose the surface must be placed on a levelling table, and on adjusting the instrument, one then sees a contour map representing the imperfections of the polished surface, it being presumed that the mirrors are optically perfect. It may be asked, why use so complicated an apparatus when we could just as well use a proof plate? There are two objections to the use of proof plates: one is that particles of dust are always settling on the surfaces to be tested, so that no matter how carefully one cleans them there is a risk of grit being present between the proof plane and the surface to be tested. These prevent the surfaces coming close enough together to give brilliant Newton's fringes, and there is then an almost irresistible impulse on the part of the optician to attempt to force them together, with the inevitable result of causing scratches. It may be asked why, then, are precautions not taken to avoid such dust? This is not so easy. Fig. 4 is a photograph of falling particles of emery powder in still air. The particles are illuminated by a strong beam of light which is provided by alternating current of 50 periods per second, so that there are 100 flashes of illumination per second. The exposure lasts for a long enough time for the falling particles to appear each as a discontinuous line, like a string of beads, and the distance from one of these beads to the next is, of course, the distance traversed by the moving particle in 0·01 sec.

In this way it was found that the rate of fall of emery grains of an average diameter of 0·005 cm. is 6 cm. a second, and grains of this size are quite large enough to cause very bad scratches. If now we take a similar photograph in ordinary moving air of a workshop during working hours, we find that the movement of air is such as entirely to outweigh the tendency of the particles to fall. The particles move both upward and downward, according to the eddies of the air, and at vastly greater speeds than the rate of fall due to gravity. Good ventilation requires that the air in a room in which anyone is doing hand-work should be renewed at least six times an hour, and it is extremely difficult to fulfil this condition without causing currents of air sufficient to raise particles of this size against the action of gravity.

The other objection to the use of the proof plate is that it increases the time required for the piece of work to acquire a uniform temperature, and this may waste quite a lot of time. For example, in the final stages of polishing prisms, it is essential that, before testing, the temperature should be allowed to settle down. As a rough guide one may say that a 60° glass prism, 2 in. high and of 2½ in. length of face, which is being polished by hand, requires about half an hour to settle down. If the test is made sooner, the prism may be so much distorted by inequalities

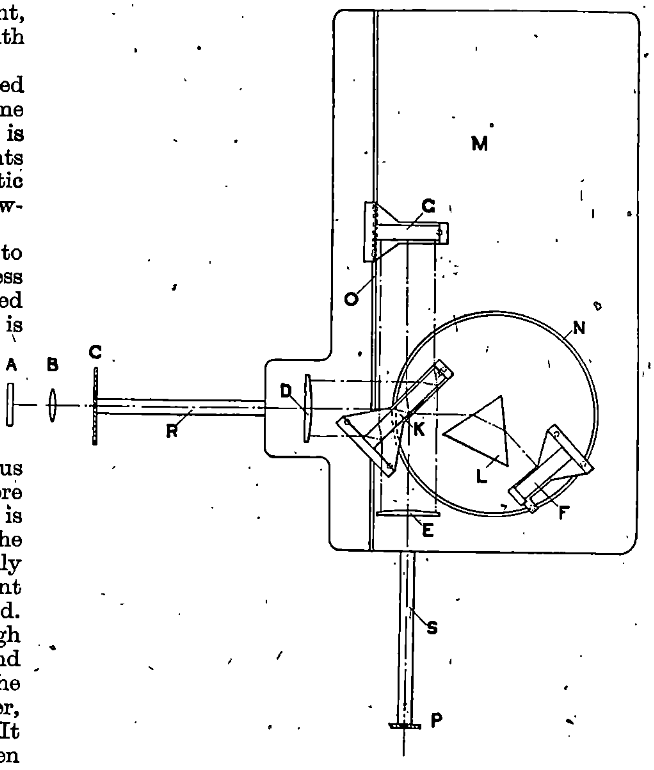

Fig. 5.

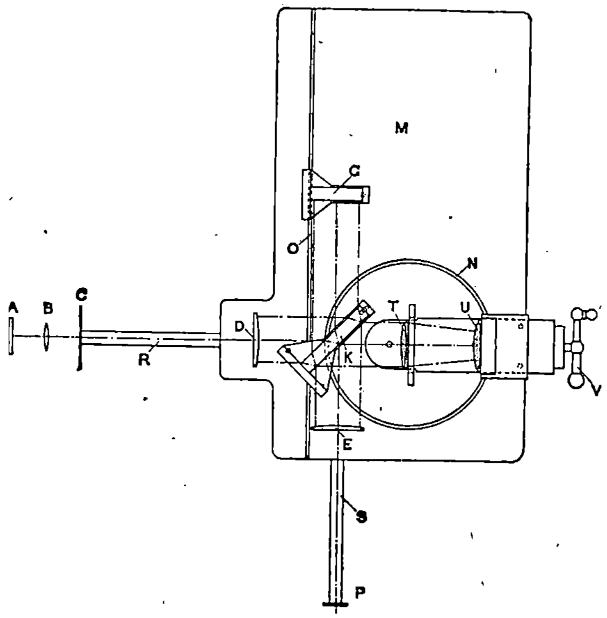

Fig. 6.

of temperature that the test is unreliable. If the test is made by a proof plate, then even if both proof plate and prism are allowed to become of the same temperature before being put together, the temperature is liable to become non-uniform owing to variation of workshop conditions. This liability is greatly reduced if the prism can be placed with all its surfaces exposed to the air, as on the interferometer.

Thus the interferometer may serve a useful purpose in replacing, on occasion, the very much simpler proof plate. This, however, is a very minor part of its use in the workshop.

All optical systems have for their purpose to receive a beam of light which originates from a point, and to alter the shape of its wave front in a predetermined way. For example : Fig. 5 shows the interferometer as arranged for testing a 60° refracting prism. Such a prism is required to receive a beam of light which has a plane wave front and to deliver it after transmission also with a plane wave front. If the wave front is distorted, whether that be due to the surfaces not being flat or the glass not being homogeneous, the appearance seen by the observer on the interferometer is an interference pattern which represents, in the form of a contour map, the aberrations of wave front produced by passage of the beam twice through the prism. We can, as it were, apply a proof plane to the wave front to ascertain how much it has been distorted by a piece of optical work.

Fig. 6 is an interferometer to which additions have been added for testing lenses. The right-hand mirror of the instrument has been removed and replaced by an optical system consisting of the lens *T* under test and the convex mirror *U*, so arranged as to send the rays back along their own path. If a plane wave falls on *T*, it should then, if the lens and mirror are perfect, emerge from *T* on its return path, still in the form of a plane wave. If it does not, we can see exactly what parts of the lens are responsible for the error and can usually, at the same time, judge quite easily from what cause the error arises.

There is a specialized form of instrument to deal with photographic lenses. Fig. 7 shows the appearances seen with a lens on the camera lens interferometer for a point off axis. The error is that characteristic of the form of aberration known as 'coma'.

The interferograms, if I may call them so, are, then, contour maps to a scale of half wave-lengths of the errors of wave surface caused by transmission through, or reflection from, the object under test.

Having observed in this way what is the error of wave front produced by an optical element, what is the optician to do about it ? That depends on practical considerations. If the piece is one of a number made together in a block, he may put it back with others for re-working. But first of all it is highly desirable that he should know whether the defect is due to the glass not being homogeneous or to the surfaces being imperfect, for if he has a number to do and the glass is heterogeneous, his production may easily be reduced to less than one half of what it is when the glass is perfect; and it may be cheaper, and indeed quicker, entirely to reject that particular batch of glass and go on to another.

For making such a decision the interferometer is invaluable. Suppose we are dealing with the production of high-quality plane parallel glass, and are having trouble of this kind, we can, with the utmost ease, determine both the variation of refractive index and the variation of thickness. We map out upon the surface of the plate, first the interference pattern obtained by the ordinary use of the interferometer, and then the pattern obtained by back reflection from the two surfaces—this can be done on one and the same instrument. Then it is a matter of quite simple arithmetic to say what are the differences of thickness and of refractive index at the points where the lines of the two patterns cross. An accuracy of 5 units in the sixth place of decimals in the refractive index, and 10^{-6} in. in the thickness, can be attained in this way.

If it is the refractive index that is at fault, and there is no other glass available, the optician may proceed to correct the optical performance by retouching. With the interferometer this is an extremely simple operation—as simple as levelling a seed bed in a garden. One rubs with a rouged pad on the high places until the interference appearances show that the work is good. The interferometer tells exactly where to rub and how much.

Now to give an illustration of other uses of the instrument.

Let us suppose that two 60° angles are to be compared, one being the standard. One prism is stood

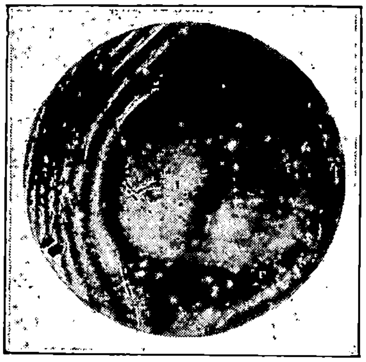

Fig. 7.

on the other, and they are placed on the instrument in place of the mirror *F* (Fig. 5) so that the interference fringes are obtained from both surfaces. The top prism is then tapped gently until the face under observation is parallel to that of the standard. Both prisms are now rotated so that their other faces are presented to the beam. Needless to say, this rotation must be very carefully done to avoid shifting the top prism relative to the bottom one. A slight rotation must now be given to the diagonal plane of the interferometer, in order to make the fringes on the standard horizontal. Then if there is any angular difference between the prisms, the fringes seen on the other prism will be tilted, the number of fringes cutting the horizontal separating line being a measure of this angular difference. If the interference bands are formed by the green light of a mercury vapour lamp, each band represents 10^{-5} in.

To test the 90° angle of a roof prism the side mirror *F* of the instrument is swung round to the right-angle position and the roof prism placed on a table of suitable height to reflect the light on to the mirror. The appearance of two horizontal bands indicates that the angle of the roof is not quite 90°. If the angle is smaller than 90°, then by pulling the telescope rod gently in a downward direction (which increases the path length of the light reflected in mirror *G*), the fringes will move inwards towards the dividing edge.

VENEREAL DISEASE

LIAISON BETWEEN SERVICE AND CIVIL AUTHORITIES

By MAJOR J. MARSHALL, R.A.M.C.

FOR the past two years, in the treatment of venereal disease, the Services in Great Britain have had the help and co-operation of certain civil clinics. Under a scheme devised by the Ministry of Health and the Service authorities, these clinics agreed to carry out surveillance and after-treatment of Service venereal disease cases on the same lines as those used in Service hospitals and clinics. Often the use of civil clinics has meant an immense saving of time and transport in districts where there is no convenient Service venereal disease centre. The purpose of this article is to show how the scheme is working in the Eastern Command and London District.

Service men who contract venereal diseases are always admitted to a Service hospital and are treated there until they are free from symptoms, non-contagious, and fit to resume full duties. After-treatment or surveillance is carried out at the clinic, civil or Service, nearest the man's station. Before a man leaves hospital, he is given verbal instructions regarding his after-care, and his medical officer receives a proforma giving the address of the chosen follow-up centre and naming the date and time for the first appointment. If the man is to attend a civil clinic his medical officer sends with him a case record card each day he attends. On this card is a pencilled scheme of treatment for the guidance of the civil specialist. It is appreciated on both sides that this is only a guide and does not apply where the civil specialist finds that other measures are necessary. A list of all clinics, civil and Service, in the area is sent to the unit medical officer when necessary. Regimental medical officers are encouraged to get in touch with the specialist at the local venereal disease centre whenever possible so that the best arrangements can be made to accommodate Service cases at the clinic.

If a Service man, without first consulting his own medical officer, visits a civil clinic and is found to be in an acute infectious condition, the specialist advises the man to report at once to the military authorities so that he may be admitted to hospital.

Civil clinics have no means of check on Service defaulters as, for reasons of security, unit locations cannot be disclosed. Most clinics, however, send lists of defaulters periodically to the Command venereologist, and the men are traced. In most cases they are found to be continuing treatment at another centre after a unit movement, but if they are true defaulters, arrangements are made for them to resume treatment.

Some civil clinics have arranged special sessions for Service cases and all have helped greatly in their efforts to deal quickly with Service men so that there shall be the least interference with duty. In certain clinics, where time, pressure of work, or other reasons have made it difficult for the civil staff to deal with Service men, the clinic has been lent to the Command venereologist for a few hours each week, and a special Service clinic has been opened.

For men leaving the Services before treatment is completed, arrangements are made for them to continue at the civil clinics nearest their homes.

Every effort is made to bring the female source of infection under treatment. When a patient knows by whom he has been infected, he is encouraged to write to the woman, telling her of the importance of seeking medical advice, and enclosing a sealed addressed letter for her to take to the specialist at the civil venereal disease clinic nearest her home. This letter informs the specialist of the nature of the suspected disease. When his patient permits, the specialist informs the sending hospital that the woman has attended and of his findings. The number of women brought under treatment by this method has more than justified the scheme.

When dealing with marital cases it is often a great help in avoiding family upsets if the same doctor can deal with both parties. This is especially the case in those instances where a man has unwittingly exposed his wife to infection during the incubation period of one of the venereal diseases, and commanding officers are co-operating by allowing a man time off to accompany his wife to the clinic on the first visit. In this connexion the London Lock Hospital has helped by lending its female clinic for a morning each week when the Command venereologist may see Service men's wives who are resident in London. The Command specialist is able to transfer to members of the honorary staff of the hospital any special cases falling outside the province of venereal disease, such as obstetric or gynæcological conditions.

In conclusion, it may safely be said of the collaboration of the civil and Service venereal disease systems that both sides have done their best to make the scheme a success, and that the results have been most encouraging. The thanks of all concerned are due to the civil venereologists, public health and hospital authorities who have assisted so greatly in this matter.

OBITUARIES

Sir Henry Miers, F.R.S.

Sir Henry Miers passed peacefully away on December 10 in his eighty-fifth year at his home in West Hampstead after a fortnight's illness. A man of unusual versatility, he gained eminence as a mineralogist and crystallographer, as a university administrator, and as a museum authority. Having had the advantage of what was commoner in his day than now, a classical education, before taking to mathematics and science, he had the gift of a fluent and lucid style of writing, as is evident in his numerous publications. Despite the partial failure of eyesight which afflicted him in his closing years and restricted his activity, he maintained up to the end his interest in all the matters that had formerly occupied his attention. When reading became difficult, he took up as a hobby the study of plants.

Henry Alexander Miers came of a family that had already shown some proclivity towards science. John Miers, F.R.S., well known as a civil engineer and in his later years as a botanist, who accompanied the great seaman, Lord Cochrane, at his invitation to South America in 1818, in order to develop the mineral resources of Chile, and in the course of his travels made an extensive collection of South American plants, now in the British Museum, was his grandfather, and Edward John Miers, who was on the staff of the Zoological Department of the British Museum from 1872 until 1885, when ill-health compelled his retirement, and was an authority on Crustacea, was his elder brother. He himself was born at Rio de Janeiro on May 25, 1885, his father, Francis Charles Miers, being at that time in business there as a civil engineer.

Miers was educated at Eton College, where he was a King's Scholar, from 1872 until 1877, and at Trinity College, Oxford, where he held a classical scholarship, from 1877 until 1881. He transferred his studies to mathematics, however, and graduated with second-class honours in mathematical moderations in 1879 and finals in 1881. In 1900 he proceeded to the newly instituted degree of D.Sc.

On going down from Oxford, Miers joined the staff of the Mineral Department of the British Museum on the inducement of Mr. (afterwards Sir Lazarus) Fletcher, who was keeper, in 1882, very soon after the removal of the collection from Bloomsbury to the new building at South Kensington. He assisted in the arrangement of the specimens in the Mineral Gallery and in the preparation of the crystallographic catalogue which had been projected. As the result of his studies he published numerous articles and memoirs on the morphology of various minerals. With his museum duties he combined the post of instructor in crystallography at the Central College, South Kensington, from 1886 until 1895. He was editor of the *Mineralogical Magazine* from 1891 until 1900.

In 1895, when N. Story-Maskelyne retired from the chair of mineralogy at Oxford and the opportunity was taken to revise the post, Miers was appointed to fill the vacancy and became the first Waynflete professor, the post having been combined with a fellowship at Magdalen College. Hitherto only courses of lectures had been given, so that Miers had as his first task to effect teaching arrangements and organize laboratory work as well as improve the mineral exhibition in the University Museum. Among his earliest pupils was H. L. Bowman, who became so fascinated with the subject that he remained to assist him, and eventually succeeded him in the chair. Miers took up a task which he had in his mind for some time, namely, the preparation of a comprehensive treatise on mineralogy; it was published in 1902 ("Mineralogy: An Introduction to the Scientific Study of Minerals", Macmillan). The second edition, which appeared in 1929, was undertaken by Bowman. During this period Miers carried on the research, upon which he had been privately engaged in London, on the conditions which determined the kind of crystals formed in a saturated solution, and cleared up many obscure points.

While at Oxford, Miers soon acquired a reputation for administrative ability, and consequently, when in 1908 a successor to Sir Arthur Rücker was sought in the difficult and onerous office of Principal of the University of London, he was chosen. Although no great changes occurred during his period of office, it was in the following year that a Royal Commission was appointed under Lord Haldane's chairmanship to investigate the whole question of university education in London. It reported in 1913, but owing to the outbreak of war in the following year, nothing was then done to carry out any of the recommendations in the report. Soon after, in 1915, Miers was translated to Manchester as vice-chancellor of the University, and such success did he achieve in this office that he was pressed to remain after reaching the normal age for retirement, and did not vacate the post until 1926. It was a great pleasure to him to return to teaching by acting as professor of crystallography.

When he had finished at Manchester, Miers returned to London to live, and settled down at West Hampstead for the rest of his life. He was by no means idle: he was promptly elected a trustee of the British Museum, thereby creating a precedent, for never before had a former member of the staff become a trustee, and was also appointed a member of the Royal Commission on National Museums and Galleries, which issued its interim report in 1928 and its final report in two parts in 1929 and 1930, and in 1931 of the newly created Standing Commission on Museums and Galleries. Simultaneously, he was invited by the Carnegie United Kingdom Trust to report on the museums, other than national, in the British Isles, and with the help of S. F. Markham did so in 1928. Almost immediately afterwards, the Carnegie Corporation of New York asked him to make a similar survey of the museums in British territory overseas. With the aid of S. F. Markham, C. Squire, and D. W. Herdman he reported on the museums in Canada and British Africa in 1932; he himself visited both countries. It was an obvious consequence of this work that in 1928 he was elected president of the Museums Association, and once again he proved so successful that he was prevailed upon to continue in office for an unprecedented length of time, and did not vacate it until 1933.

During 1904–9 Miers was president of the Mineralogical Society, and during 1932–37 of the Gemmological Association. In 1941, owing to his defective sight, he was compelled to resign from the trusteeship of the British Museum and membership of the Standing Commission on Museums and Galleries. He was knighted in 1912, elected a fellow of the Royal Society in 1896, and awarded the Wollaston Medal by the Geological Society of London in 1934. Numerous other distinctions, including honorary degrees, were conferred upon him.

G. F. Herbert Smith.

Dr. E. J. Allen, C.B.E., F.R.S.

THE Rev. Richard Allen of Lancashire, and his wife Emma Johnson, of Bideford in Devon, had good reason to be proud of their family of eight, which consisted of five sons and three daughters, four of whom survive. The sons were the late Dr. H. N. Allen, professor of electrical engineering and afterwards principal of the College of Science at Poona; the late Mr. C. B. Allen, assistant general manager of the Midland Bank; the late Dr. E. J. Allen, F.R.S., until 1936 director of the Marine Biological Laboratory at Plymouth; Mr. E. L. Allen, of the School of Art, Redditch; and Dr. H. S. Allen, F.R.S., professor of natural philosophy at St. Andrews.

Edgar Johnson Allen, the second son, was born at Preston in 1866, educated at Kingswood School, Bath, and at the Yorkshire College, Leeds. He graduated as an external student of the University of London with honours in chemistry in the Intermediate B.Sc. (1884) and physics in the Final B.Sc. examination (1885). For financial reasons some years were spent in teaching posts, including the headmastership of a school in the West Indies. After his return to Europe, he was engaged in post-graduate study in zoology in the University of Berlin and also at University College, London. In 1900 he graduated as D.Sc. in the University of London and won the Sherbrooke Scholarship. He had already received a research grant from the Royal Society (1893) which enabled him to work at Plymouth.

In 1895 he became director of the Marine Biological Association's Plymouth Laboratory and secretary to the Council, posts which he held for forty-two years, until his retirement in 1936. Under his guidance the Laboratory prospered and became a centre of marine research. It became a centre of physiological research also, for Allen realized the importance of marine animals and plants as subjects for the study of general problems of biology and medicine. Accordingly, it came about that the last scientific paper read by one of his old staff on his way to take up duty as a naval officer was before the Royal Society of Medicine upon the semi-circular canals of the ear, studied through the response of single nerve fibres.

During the earlier years much of the research and the observational work at sea were carried out by Allen himself. But as years went on his duties as director became more arduous and his time was occupied with routine, with advising younger men and attending to the wants of the numerous research workers who came to the Laboratory from distant lands. The impact of the visitors upon the regular staff was, in his view, specially good for the latter, and tended to prevent the departmental miasma of an official laboratory from enveloping them. It was, therefore, a pleasure to him when his attention was directed to Sir Lawrence Bragg's presidential address to the Institute of Physics last July and it was suggested that his moulding of a research institution was upon the lines considered by Bragg to be most desirable.

But though his unremitting and unselfish care for his laboratory left him little time, Allen contrived also to be a good Plymothian and served upon a number of committees. He gave much thought also to the Tees and Mersey Survey Committees of the Department of Scientific and Industrial Research and to the work of the Water Pollution Research Board.

Allen's work brought him general recognition in the learned world. In 1914 he was elected a fellow of the Royal Society. In 1922, at Hull, he was president of the Zoological Section of the British Association. In 1923 the Hansen Memorial Medal and Prize came to him from Denmark. In 1926 he received the Gold Medal of the Linnean Society, followed by the Darwin Medal of the Royal Society in 1936 and the Agassiz Medal for Oceanography of the National Academy of Sciences, Washington. In the previous year he had been made C.B.E. He was also a foreign member of the Royal Academy, Denmark, and an hon. LL.D. of the University of Edinburgh.

Of Allen's forty-three published papers and addresses, twenty-five appeared in the *Journal of the Marine Biological Association*, which he edited for so long. Some of his best early work on the nervous system of the Crustacea appeared in the *Quarterly Journal of Microscopical Science*, and other work on crustacean embryology and histology appeared in the *Proceedings of the Royal Society*; while his work on regeneration and reproduction of the Syllid Procerastea was published in the *Philosophical Transactions*. His work on the culture of planktonic diatoms opened up a trail which has since been actively followed. Of his papers two, on estuarine fauna, were with R. A. Todd. The first diatom paper was with the late E. W. Nelson and in two, dealing with the genetics of Gammarus, he collaborated with Mrs. E. W. Sexton.

E. J. Allen's end came peacefully on December 7 after one day of indisposition, while still full of interests and enjoying a retirement with leisure he had previously lacked. W. R. G. ATKINS.

Lieut. W. Neil Paton, D.S.C., R.N.V.R.

AFTER many valiant aerial combats, which won him the Distinguished Service Cross and a mention in dispatches, William Neil Paton was reported missing off Malta in June last and has now been officially presumed killed. Marine biology has lost a recruit of great promise. Born in September 1914, the second son of Dr. and Mrs. J. Hunter P. Paton of St. Andrews, he was educated at Oundle and Magdalen College, Oxford. After graduating in 1937 he joined the Oxford University Expedition to Grand Cayman and returned in the following summer with a rich zoological collection. He then joined me in experimental work on the vertical migration of the marine plankton being carried out at the Millport Marine Station and was later appointed to the research staff of the Station.

Soon after the outbreak of war, Paton volunteered for service with the R.N.V.R., and received his commission in the spring of 1940. Later he transferred to the Fleet Air Arm and was stationed at Malta. The Admiralty reported the award of the D.S.C. in the following terms: "for outstanding courage and determination in the face of the enemy. This officer carried out sixteen air operations from Malta in all of which he made contact with the enemy and in seven of which enemy shipping was destroyed or damaged. On eight of the operations he was leading the force and was largely responsible for its success". He was mentioned in dispatches for his last action: "the enemy ships, escorted by a strong force of shore-based fighters, were attacking an allied convoy bound for Malta when our aircraft engaged them and pressed home a determined attack in the face of bitter resistance".

Paton threw himself into his scientific work with the same determination; he was a splendid experimenter, never discouraged by failure, always seeking a way to get over difficulties. I am at present preparing his work for publication. He was a man of wide interests and a very human personality, endearing himself to all he came in contact with. To end this brief note I cannot do better than quote a letter from his Oxford tutor: "it is a literal statement of fact to say that life is poorer because one has not sometimes the thought that Neil Paton may be coming around".

Our sincerest sympathy goes to his parents who lost their other son, also in the Fleet Air Arm, in the same way: missing, then presumed killed.

A. C. HARDY.

WE regret to announce the following deaths:

Prof. Rudolf Abel, formerly professor of hygiene in the University of Jena, the eminent German bacteriologist, aged seventy-four.

Prof. F. D. Adams, F.R.S., emeritus Logan professor of geology, dean of the Faculty of Science and vice-principal, McGill University, on December 27, aged eighty-three.

Prof. Franz Boas, emeritus professor of anthropology in Columbia University, on December 21, aged eighty-four.

Dr. Mabel C. Buer, lecturer in economics in the University of Reading, on December 9, aged fifty-one.

Sir Bryce Chudleigh Burt, C.I.E., M.B.E., director of animal feeding stuffs, Ministry of Food, secretary of the Indian Central Cotton Committee during 1921–28, agricultural expert to the Imperial Council of Agricultural Research during 1929–35, on January 2, aged sixty-one.

Prof. W. Caldwell, emeritus professor of philosophy in McGill University, aged seventy-nine.

Prof. F. M. Cornford, F.B.A., emeritus professor of ancient philosophy in the University of Cambridge, on January 3, aged sixty-eight.

Mr. F. W. Harbord, C.B.E., the well-known metallurgist, on December 27, aged eighty-two.

NEWS and VIEWS

New Year Honours List

THE following names of scientific men and others associated with scientific work appear in the New Year honours list:

Baron: Sir Charles Wilson, president of the Royal College of Physicians.

Baronet: Mr. W. M. Goodenough, chairman of the Nuffield Trust for the University Medical School, Oxford.

G.B.E.: Sir Henry Dale, lately director of the National Institute for Medical Research, president of the Royal Society.

K.C.B.: Sir Wilson Jameson, chief medical officer, Ministry of Health and Board of Education.

Knights: Prof. J. H. Clapham, president of the British Academy; Prof. F. Clarke, professor of education, University of London; Prof. A. C. G. Egerton, professor of chemical technology, Imperial College of Science and Technology, and joint secretary of the Royal Society; Jhanendra Chandra Ghosh, director of the Indian Institute of Science, Bangalore; Mr. S. H. Howard, inspector-general of forests and president of the Forest Research Institute, Dehra Dun; Pestonji Rustom Masani, lately vice-chancellor of the University of Bombay; Mr. W. A. Stanier, chief mechanical engineer L.M.S. Railway and scientific adviser to the Minister of Production; Brig. E. O. Wheeler, surveyor-general of India; Mr. J. Wright, chief engineer, Central Electricity Board.

C.M.G.: Mr. D. Yates, a leading metallurgist of South Australia.

C.I.E.: Bhagavathulu Viswanath, officiating director, Imperial Agricultural Research Institute, New Delhi; Mr. R. A. MacGregor, chief metallurgist, Department of Supply, Calcutta.

Prof. G. A. R. Kon

PROF. G. A. R. KON, whose appointment to the chair of chemistry at the Chester Beatty Research Institute, Royal Cancer Hospital (Free), was recently announced, is a graduate of the University of Cambridge; but his career as a chemist has until now been connected with the Imperial College of Science and Technology. Beginning research there in 1914, he was one of the band of workers associated with the late Sir Jocelyn Thorpe in the founding of his school of organic chemistry. Prof. Kon's early work dealt with ring formation and the like, and in the course of it he came across certain ketones exhibiting unusual properties. After the presentation of his D.Sc. thesis in 1922 he followed up these early observations, embarking on a long series of investigations dealing with three-carbon tautomerism, a phenomenon which had not, until then, received systematic attention. One outcome of this work, to which Prof. R. P. Linstead also made substantial contributions, was the elucidation of the chemistry of the glutaconic acids. The contradictory nature of these compounds, which had previously been the subject of controversy between Thorpe's school and that of Feist in Germany, was shown to be due to the simultaneous existence of three-carbon tautomerism and stereoisomerism.

In 1932 Prof. Kon wrote the section on homocyclic compounds in the "Annual Reports on the Progress of Chemistry", and this date marks a complete change in the direction of his work. Having been hitherto concerned solely with aliphatic compounds, he directed his attention to problems connected with the sterols and related substances. He synthesized "Diels's hydrocarbon", $C_{18}H_{16}$, which forms the basis of the sterol skeleton, and helped to evolve the formula of the cardiac aglucones on the basis of the degradative work of Jacobs on strophanthidin. He then turned his attention to the triterpenes. Aided by a number of capable pupils, he largely elucidated the constitution of bassic and quillaic acids. The latter result, in turn, necessitated the revision of the structure of related compounds belonging to the β-amyrin group, for which a new formulation was proposed. A feature of this work, made possible by collaboration with P. Bilham, was the use of the surface film method for ascertaining the position of the functional groups in these large molecules.

William Hedley : Locomotive Pioneer

ON January 9, 1843, William Hedley, one of the pioneers of the locomotive and iron railway, died at Burnhopeside Hall, near Lanchester, Co. Durham, and was afterwards buried at his birthplace, Newburn on the Tyne. He was then sixty-three years of age, having been born on July 13, 1779. He seems to have had a good education and in his 'twenties became a viewer at the colliery in the village of Wylam, eight miles west of Newcastle-upon-Tyne, where George Stephenson was born in 1781. The colliery was the property of Christopher Blackett, a man with progressive ideas, who in 1804–5 had had a locomotive built at Gateshead to Trevithick's plans. This engine, it appears, was never put into service. In 1811, with Blackett's approval, Hedley made both model and full-size experiments to show that a locomotive with smooth wheels could operate successfully on smooth rails. These experiments led to the construction of some of the earliest locomotives, which were used for the transport of coal from Wylam Colliery to the staithes at Lemington, five miles lower down the river. One of these engines, supposed to have been built in 1813, is the historic *Puffing Billy*, now in the Science Museum, South Kensington. Hedley was as much concerned with the winning of coal as its transport, and during the last twenty years of his life worked or owned various mines in Durham and Northumberland. His own share in the development of the locomotive was clearly stated by him in a letter of December 10, 1836, to Dr. Lardner, who in a lecture at the Literary and Philosophical Society, Newcastle, had spoken of George Stephenson as the "Father of the Locomotive".

Chemical Industry in Europe

IN a recent issue of the *Chemiker Zeitung* an attempt is made to show that chemical industry in Europe is gradually increasing its productive capacity; to such an extent indeed that, after the War, Europe will be entirely independent of Anglo-Saxon domination. Presumably under the beneficent leadership of Germany, together with the organizing and technical skill that this is supposed to include, Europe would no longer need foodstuffs and raw materials from the British Empire: these would be replaced by synthetics, and the reign of *Ersatz* would be almost universal. A survey is made of the chemical industries of the chief European countries, from which Germany, and, of course, the U.S.S.R., are excluded, as also is Turkey. Many of the data, however, are pre-war, or hopeful forecasts of the future. This is more particularly the case with Italy, where some index figures are quoted for the period 1935–39 to show the rapid rise in her chemical output. In France also, practically all that could be said is that a large company has been formed for the production of synthetic fuel from lignite. It is said to be financed by the Banque de Paris, doubtless backed by German financiers or industrialists; but it will be three years before the requisite plant, using the Fischer-Tropsch process, can be installed.

If the intention was to show that European chemical industry, apart from spasmodic attempts to increase output of war munitions, is laying firm foundations for post-war expansion or even taking any appreciable steps in that direction, then the record, on the German writer's own showing, indicates complete failure. As a piece of propaganda it could scarcely deceive even the Germans themselves. Much more space, indeed, is devoted to countries not yet overrun by the Nazis, such as Spain and Sweden, and it is clearly and indubitably shown that only in those countries has any real progress been made in the chemical and allied industries. This is confirmed by non-German and more reliable sources. As a matter of fact, in the German record, many important items are omitted, as if the writer had suddenly realized that he had already said too much and exhibited too painfully the great contrast between German-occupied and unoccupied Europe. Spain's progress in the matter of nitrogenous and other fertilizers is described at some length, and reference made to new factories for the manufacture of tanning materials, sulphur and copper from pyrites, leather, textiles and artificial fibres. Many of Sweden's recent developments in chemical industry are also noted. Compared with these, the few details given about the occupied countries are insignificant trifles, and relate mainly to more or less temporary expedients to replace with indigenous products those which can no longer be obtained from Germany.

The U.S.S.R. in War-time

THE broadsheet "Soviet Planning in War-Time" issued by P E P (Political and Economic Planning) gives a useful objective account of the ways in which the Russian economy has advanced from one mobilized for war in 1941 to a battle economy, and of the general background of this economy. The machinery of Soviet planning functions through three main stages: first, a comprehensive survey of existing resources; secondly, the formulation of a plan, which is simply the laying down of a series of output programmes which must be carefully dovetailed into each other so that they are consistent; and, thirdly, a mechanism for checking their progress and for providing the elasticity necessary for periodic adjustments. This machinery was evolved over a considerable period of time, and the broadsheet gives a brief account of the purposes and achievements of the three Five-Year Plans. It was only during the Second Five-Year Plan that the consumption of foodstuffs and living standards generally rose to any appreciable extent, but an important aspect of that period was the development, partly for strategic reasons, of industrial and raw material resources east of the Urals. Both the First and the Second Five-Year Plans between them largely achieved their objectives of the creation of modern large-scale industry and a mechanized agriculture as the basis for raising living standards to a higher level and for national self-sufficiency in war-time.

The Third Five-Year Plan provided for further increases in the output of industry and agriculture, but its most striking feature was the huge increase in the resources devoted to defence. Moreover, the whole organization of Russian economic life, with its machinery for central planning and its high degree of military preparedness, makes for a greater degree of continuity between peace and war economies than in any other country except Germany. Owing to the absence of excess capacity, the war sector from the outset had to be expanded at the expense of the peace sector of the economy. The producers' goods industries were, so far as possible, adapted to war production and the output of these industries was reduced. Agriculture was seriously affected by labour shortage due to mobilization, which was only in part made up by urban workers and spare-time labour. Excess purchasing power seems to have been skimmed chiefly by increased subscription to State loans. To offset the heavy losses in production resulting from Nazi occupation of European Russia, great efforts, apart from the evacuation of industrial plant and rolling stock, have been made to increase the absolute absorptive capacity of the Ural and Asiatic regions. New sources of raw materials are being exploited, new power stations established, new coal pits sunk and new oil wells drilled. New plantations of rubber-bearing plants, of sugar beet, etc., have been developed, and new substitutes and methods are being employed for the manufacture of sugar and soap. In all this, scientific workers have played a great part, as well as in the simplification and rationalization of many technical processes.

The Solway Tides

A great tidal wave occurred on the Solway estuary on the night of December 9–10, when 3,000 acres between the Rivers Sark and Esk were under water and Sark Toll Bar marriage house was isolated, while 7-ft. fences on Sark Foot farms were submerged. The tide was 25 ft. and was made abnormal and destructive by the wind that came in the wake of a great tidal wave. On the Scottish side the floods reached the highest recorded level since 1900, cattle and sheep were drowned, farmhouses isolated. A 9-ft. embankment was broken in two places along the River Annan and houses were flooded in the Scottish town of Annan. It might have proved more costly but for the fact that because of the mild weather few farmers had brought their sheep down from the mountains to the estuary marshes. The Solway Firth has a history of great tides serious to local farming. Some years ago a tide with less water than that of December 9 killed nearly 1,000 sheep, owing to all the winter flocks being on the marshes. In 1942 the Solway had its usual two high tides of the year, in August and November, and the December one was unexpected.

English Lakeland Fauna

There has been a considerable extension of our knowledge of the fauna of the English Lakeland by the activities of the Carlisle Natural History Society. A list of 292 species and sub-species has been drawn up in a manuscript book on "The Birds of Lakeland" to be published after the War, a considerable number of nesting species being added to the Rev. MacPherson's old "Fauna of Lakeland". At a recent meeting of the Society in Carlisle Museum, F. H. Day recorded six new species of Coleoptera added to the Cumberland list in 1942, bringing the total list to 1,849. The new additions are *Triplax aenea*, Schall.; *Gabrius velox*, Shp.; *Aphodius constans*, Duft.; *Liodes glabra*, King.; *Hylastes opacus*, Er.; and *Scolytes intricatus*, Ratz., from an oak log. It was also reported that in 1942 there had been an increase in the range of wall brown and peacock butterflies, also the cinnabar moth in coastal regions, while the rare greasy fritillary butterfly still maintained certain local haunts. A cream-coloured curlew nested at Hosketh Hill and the quail in a clover field at Durdar. The blackcock is still numerous in many haunts. There is a regular pied wagtail roost on the glass roof of Carlisle railway station and another roost in willows by the Caldew. The willow-tit has been recorded in a number of Lakeland localities and a grey shrike was reported from near Brampton at the end of November. Whooper swans remained on a local water until the second week of May.

Earthquakes Registered in Spain

During September 1942, thirteen strong earthquakes were registered by the seismographs at the observatory at Toledo. On September 1 there were three shocks, the first beginning with *iPz* at 9h. 47m. 34s. U.T., attaining an amplitude of 13 μ on the N.S. component at 9h. 52m. 01s. U.T. and finishing at 10h. 50m. U.T. The shock apparently came from an epicentre distant 2,980 km., the focus being some 250 km. deep. The other two shocks were much smaller. The earthquake on September 6, which registered at 16h. 06m. 34s. U.T., came from an epicentral distance of 9,470 km. and that on September 9, which registered at 1h. 37m. 59s. U.T., from an epicentral distance of 9,245 km. On September 24 an earthquake which began registering at 3h. 56m. 34s. U.T. attained an amplitude of 11 μ at Toledo at 4h. 42m. 46s. U.T. and finished recording at 5h. 10m. 00s. U.T. It came from an epicentre distant probably 11,710 km. The last earthquake registered in the month was on September 26 at 4h. 12m. 09s. U.T., probably from an epicentral distance of 8,465 km., and finished recording at 4h. 50m. U.T. The readings during the month were to a small extent confused by microseisms, and all readings are tentative.

Comet Whipple

Dr. W. H. Steavenson observed this comet on December 19, 22 and 29. On the last occasion he described it as large, at least 10′ in diameter, with a well-marked nucleus and a tail about 20′ long. Its magnitude was about 6 on December 29. As Dr. Steavenson is at present absent from his observatory, he was able to give only approximate positions of the comet by using a 3-in. refractor on an altazimuth mounting and estimating the positions from stars in the field. From his data Dr. M. Davidson has computed the following orbit and ephemeris, but they are only approximate owing to the nature of the observations. Those who observe the comet in the early part of the month, for which the ephemeris will probably suffice, should make the necessary corrections for later observations. The comet is approaching the earth and will be about 30 million miles away on January 28. It will almost certainly become a conspicuous naked-eye object during the month.

Crystal Photography with Divergent X-Rays

KOSSEL[1] has shown that when a single crystal is used as anticathode in an X-ray tube, the divergent characteristic X-rays generated in the crystal are diffracted, according to the Bragg relation, from the various planes in the crystal itself, and a photographic film placed in the neighbourhood of the crystal will show a pattern of black and white lines (conics if the film is plane) on a more or less uniform background. These are somewhat similar to the more familiar Kikuchi lines[2] obtained by electron diffraction methods, but they are much fewer in number and are better resolved. However, Kossel lines can only be recorded when the crystals used contain elements of fairly high atomic number. Fujiwara and Onoyama[3] have obtained similar black and white lines *within the central shadow* by using a convergent primary X-ray beam; and Linnik[4] predicted in 1929 that they would also be obtained by the use of a beam diverging from a pin-hole, but suggested that the inevitable background would spoil the pattern.

This is not necessarily the case. Using a very low input tube designed by Dr. A. Müller, which gives a beam of copper X-radiation divergent externally through an angle of nearly 180°, I have obtained patterns, as shown in the accompanying reproduction, with an exposure of 30 sec. or less, the crystal being a 1·5 mm. thick plate of diamond the octahedral face of which was in direct contact with the point source on the anticathode, the photographic film some 10 cm. away. In general, such patterns can be obtained with copper radiation from any organic crystal or crystal containing atoms of low atomic weight. The lines of the pattern are mostly *deficiency* lines (black in the reproduction but white on the original film) marking those places where the primary intensity has been *reduced* by reflexion, and these cannot show up strongly unless the crystal is thick enough for considerable reflexion to have taken place during transmission. On the other hand, the crystal must not, of course, be so thick as to absorb all the copper radiation. The *reflexion* lines from a thick crystal are weak because so much multiple reflexion takes place within the crystal, and they are in any event few because most reflected rays are directed away from the film, as a simple sketch shows. A thin crystal gives weak deficiency, but stronger reflexion lines. The separation s of the deficiency and reflexion lines, measured in the plane of any incident and reflected ray, is given by $s = \frac{\sin 2\theta}{\sin(\phi+\theta)} \cdot r$, where θ is the Bragg angle, ϕ the inclination of the reflecting plane to the plane of the film, and r the distance from the point source of X-rays to the point of reflexion; s is independent of the film distance. Application of this formula shows that it is the outer layer of the crystal (farthest from the source, but nearest to the film) which is responsible for the reflexion lines found on the film.

Although most reflexion lines are not recorded on the film, deficiency lines corresponding to values of θ very near 90° may often occur in a forward direction. This enables very accurate estimates of lattice distances to be made. Moreover, one or two half-minute photographs of a suitably shaped crystal can, in theory at least, supply all the information required to ascertain the unit cell and space-group, since measurements of the co-ordinates of four points on any one deficiency curve will give D, the film-source distance, θ the Bragg angle, and λ, μ, ν (two independent) the direction cosines relative to any arbitrary axes in the crystal, of the reflecting plane. It is not necessary, although it is convenient, for the crystal to have any external faces or to be placed with its crystallographic axes in any particular positions. On account of the short exposures required, this method (which is very simple in practice) might prove to be a useful way of examining non-permanent crystals.

Refractive Index of Coals

The polarization of the light reflected from coal surfaces has been examined by use of the same apparatus which served for an examination of the intensity of the light reflected at different angles of incidence[1]. As the photocell used had a response spreading from 4500 A. to 10000 A. with a maximum at 7500 A., a water cell was used to absorb the unwanted infra-red radiation. A No. 70 Wratten Monochromat filter was placed in front of the source, and an analysing Nicol prism before the photocell unit.

The reflected intensities of the two components, plane polarized parallel to and perpendicular to the plane of incidence, resolved by the Nicol prism, were measured for various angles of incidence. With increasing angle of incidence, the intensity of the perpendicular component increased whereas the intensity of the parallel component passed through a minimum and then increased. A clearly defined minimum was obtained when the photocell amplification was increased. With visual examination most specimens gave complete extinction at the Brewster angle, but zero readings were never obtained with the more sensitive photo-electric photometer. The angle at minimum intensity was used to calculate the refractive index of the specimen.

No.	Description of sample	Refractive Index		'Fixed carbon' (dry-ash free) %	Properties of samples

Filter No. 70 (λ = 7000 A.) used throughout.

As this method is less sensitive than those available for transparent substances, special care had to be taken to estimate the position of the minimum. For each determination the galvanometer deflexions were recorded over a region of about 4° each side of the minimum, which was then determined graphically. A typical result is shown in Fig. 1. The lower curve is for a natural cleavage surface, and the upper for the same surface after polishing. This was done with fine emery papers of decreasing coarseness, rotating the specimen through 90° with each change of paper, followed by polishing on 'Selvyt' cloth with moist Goddard's Plate Powder. Although the intensity of reflected light is increased by polishing, the position of the minimum is unaltered. The results were not affected by rotation of the surface in its own plane.

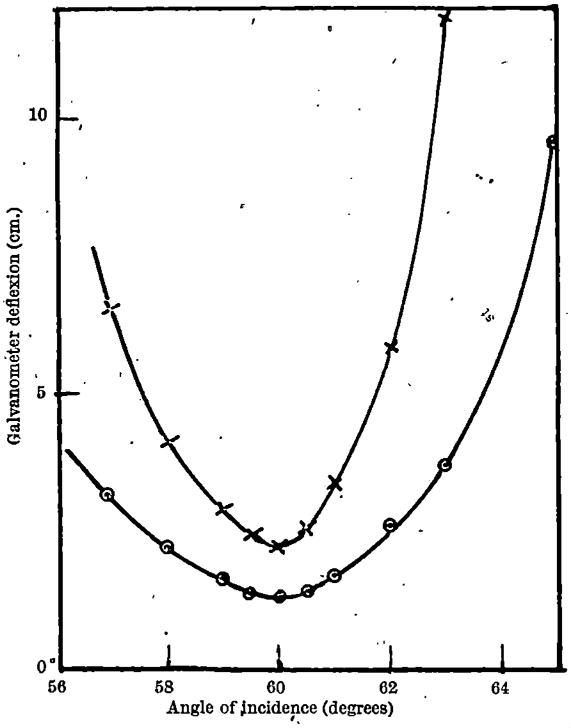

Fig. 1. Effect of polishing a coal surface. $\varphi = 60°$; tan $\varphi = \mu = 1{\cdot}73$. Crosses, polished surface; circles, natural cleavage surface.

A representative selection of results is shown in the accompanying table giving the refractive indexes, in directions parallel to and perpendicular to the bedding plane of the coals, for $\lambda = 7000$ A.

From a large range of results shown in Fig. 2 it would appear that: (i) perpendicular to the bedding plane the refractive index increases with 'rank' or geological age, as shown by the percentage 'fixed carbon' (proximate analysis), to a constant maximum of about 1·9 for anthracitic coals; (ii) parallel to the bedding plane the refractive index first increases

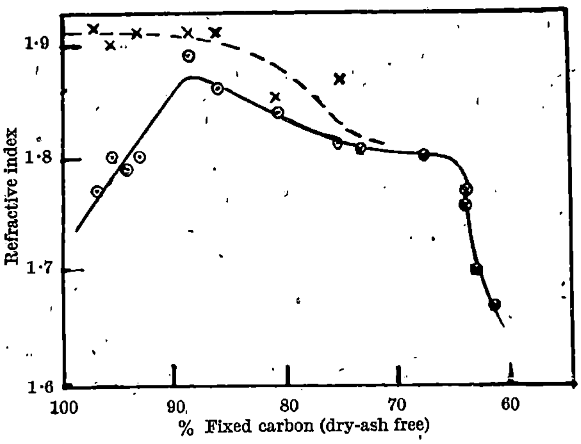

FIG. 2. REFRACTIVE INDEX IN DIRECTION PARALLEL (CIRCLES) AND PERPENDICULAR (CROSSES) TO BEDDING PLANE RESPECTIVELY.

with 'rank' and then decreases for anthracitic coals; (iii) the development of optical anisotropy coincides with the disappearance of coking properties.

For comparison, results for American coals are 1·76–1·87 for bituminous and semi-bituminous coals[2] and between 1·63 for a lignite and 1·80 for a bituminous vitrain[3]. Thanks are due to Dr. D. H. Bangham and Dr. C. A. Seyler for the loan of specimens.

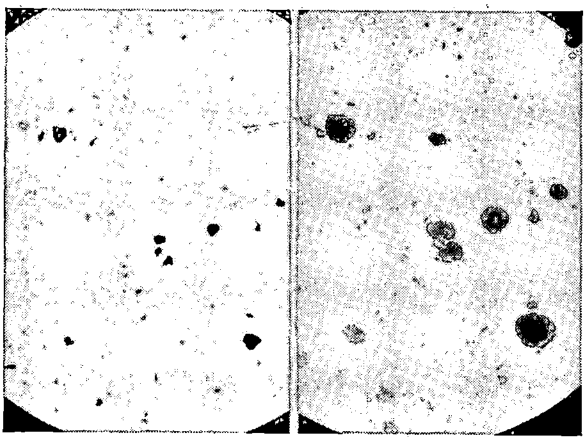
Microscope Observations of the Crushing of Coal

So far as I am aware, the peculiar effect described below of a disruptive pressure on small particles of coal has not hitherto been observed. The observations were made in the course of an examination of very fine coal dust from a ball mill which is claimed to grind coal to micron size.



Left hand: ground coal, Swallow Wood seam, dry mounted. Right hand: the same field after crushing the coal. The particles have spread and become translucent. A group of three particles have begun to coalesce to form a single sheet of substance. ×240.

The microscope showed that the sample of dust contained particles up to thirty microns in diameter. A micro-scalpel was pressed on a cover-glass near a selected particle and the effect was watched. As the pressure was increased there came a point at which the particle collapsed into smaller particles which under continued pressure spread and coalesced into a brown patch. Under further pressure the patch spread and became correspondingly lighter in colour and, when about 0·1 micron in thickness, broke into smaller pieces, and then disintegrated into a cloud of fine particles. The accompanying illustrations show the same field of a dry mount of some coal dust of the Swallow Wood seam, a coking coal, before and after it had been crushed on the slide. The particles have all spread and become translucent, and three of them in the centre of the field have begun to coalesce.

The effects of crushing vary considerably according to the type of coal, but in general it seems that coal can behave as a plastic substance. Even anthracites, which hitherto have been obtained only as opaque even in the thinnest section, have become translucent under the simple manipulation described. The observations will be published in more detail elsewhere.

Development of Penicillium on the Cut Surfaces of Certain Vegetables

WHILE making certain experiments designed to test the efficacy of various fungicides we encountered an interesting phenomenon. We noted that when the cut surfaces of potato tubers were dipped momentarily in a 2½ per cent solution of copper sulphate, Penicillium developed copiously on these cut surfaces within five days if they were kept under moist conditions, but similar untreated surfaces were uncontaminated by this or any other fungus. Further, cut surfaces of sugar-beet, turnip, Jerusalem artichoke, carrot and onion reacted similarly, although growth was less noticeable on carrot; here also untreated cut surfaces did not readily develop fungal growth.

As the effect was so striking the matter was explored further, and a similar reaction was found to occur when solutions or suspensions of other copper salts were used, namely, the acetate, chloride, nitrate, carbonate, chromate, formate and salicilate, also copper potassium sulphate and copper ammonium sulphate. With potato tubers, and when using copper sulphate, discoloration of the tissues preceded Penicillium development. It was noted, however, that with concentrations of copper sulphate below one per cent, Penicillium had not developed after seven days although discoloration had developed at concentrations as low as one in four hundred. As it was of interest to determine if this reaction could be produced with solutions or suspensions of other metallic salts, a number of these were tested, namely, the nitrates of barium, bismuth, calcium, cobalt, iron, lead, magnesium, mercury, nickel, potassium, silver, sodium, strontium and zinc. A marked and early growth of Penicillium occurred only when the cut surfaces were treated with the cobalt salt although it developed at a later date and to a much lesser extent with nickel and iron; very slight growth was noted after treatment with mercury.

A detailed account of these observations will be communicated elsewhere.

Effect of Parental Feeding on the Rate of Development and Mortality of *Tribolium destructor* Uyttenboorgaart (Coleoptera, Tenebrionidæ)

THE object of these experiments was to show the effect, on the rate of development and mortality of offspring, of feeding their parents on flour of different extractions. All experiments were carried out under the same conditions (apart from the food used), which were as follows:

Newly emerged first instar larvæ of *Tribolium destructor* (from eggs laid about 200 days after the first oviposition of the female) were put, in fours, in open 3 in. × 1 in. glass tubes; in a dark incubator; at 25° C. ($\pm \frac{1}{2}$° C.); and at a humidity of 50–60 per cent R.H. (usually about 56 per cent R.H.).

The two kinds of flour used, 85 per cent (National Wheatmeal) and 60 per cent (High Grade White Flour), were kindly provided by the Research Association of British Flour Millers, from a single sample of grain. The food was kept in the incubator, until it had reached equilibrium with the temperature and humidity, before being used; and an ample quantity (about 2 gm. per larva) was provided at the beginning of the experiments, for the full period of development, so contamination by fæces was negligible. The individuals were only examined at or near the pupal stage, and were treated very gently, so handling was inconsiderable.

In all experiments at least a hundred individuals were used, and no results, however extreme, were omitted in calculating the averages. The sexes were noted, but since they show no significant difference in length of period of development, males and females are not separated in the summaries. All figures given in the summaries show the average number of days taken from the emergence of the first instar from the egg to the eclosion of the adult from the pupa.

The mortality figures include all larval, prepupal and pupal deaths, but adult viability was not investigated. The experiments where parents were fed on 85 per cent flour, and their offspring fed on 60 per cent flour, were repeated as a check and it will be seen that the results (average 44·9; standard deviation 2·1; mortality 3 per cent) approximate very closely to those obtained in the original experiment.

The results show that the rate of development of the offspring is influenced by the food on which their parents are fed. Thus, whether larvæ are fed on 60 per cent flour or on 85 per cent flour, they develop more rapidly when their parents have been fed on 85 per cent flour than when their parents have been fed on 60 per cent flour. Indeed, so strong is the effect of parental food that larvæ develop more quickly on 60 per cent flour, if their parents have been fed on 85 per cent flour, than they do on 85 per cent flour if their parents have been fed on 60 per cent flour. Applying Fisher's t test to these results, the differences between larvæ fed on the same foods, but whose parents were fed differently, are highly significant ($P<0{\cdot}01$). The difference between the larvæ which were fed on 60 per cent and 85 per cent (parents 60 per cent) is also significant ($P<0{\cdot}01$). The difference between the larvæ whose parents were fed on 85 per cent is not significant (P between 0·1 and 0·05).

Similar conclusions are reached from a study of the mortality figures. These again show the advantage to the offspring of parents fed on 85 per cent flour, whether the offspring themselves be fed on 85 per cent or 60 per cent flour. The figures also show that the food of the parent has a greater effect on mortality than has the food of the larvæ.

These experiments are part of some work done voluntarily for the Pest Infestation Laboratory of the Department of Scientific and Industrial Research, and I wish to express my thanks to Mr. G. V. B. Herford and Dr. O. W. Richards for their readiness at all times to give help and advice.

RATE OF DEVELOPMENT

	Parents fed on 85%		Parents fed on 60%	
	Average	Standard Deviation	Average	Standard Deviation
Larvæ reared on 60%	44·4	±2·4	52·4	±5·3
Larvæ reared on 85%	43·9	±1·7	48·2	±3·8

MORTALITY

Parents fed on	85%	60%
Larvæ fed on 85%	7%	39%
Larvæ fed on 60%	14%	41%

Discoveries by Accident

PROF. RUSS will find it interesting, I think, to refer to the 1929 May Lecture of the Institute of Metals which was delivered by Sir Oliver Lodge on the theme of "States of Mind which Make and Miss Discoveries".

"It is instructive," said Sir Oliver Lodge, "to realise the state of mind which misses a discovery as well as, what is more commonly attended to, the more admirable state of mind which succeeds." Many experimenters had opportunities as good as Röntgen's to observe the X-rays which were generated in their laboratories. Sir Oliver Lodge cited the case of Rev. Frederick Smith who, on finding that the plates wrapped in a box near a tube were fogged, was—so to speak—annoyed at this disturbance of his experiments, and kept the plates out of the way.

I have always remembered the fascinating manner in which Sir Oliver Lodge elaborated the philosophy of the inventive mind in this lecture; and I have remained convinced that the "admirable state of mind" which led Röntgen to follow up his observation fully entitles him to recognition as the *discoverer* of X-rays.

RESEARCH ITEMS

Wooden Implements of a Primitive Tribe

An interesting light is thrown on the possible methods of early man by a description of modern stone-age man in the Musgrave Ranges of South Australia ("An Unrecorded Method of Manufacturing Wooden Implements by Simple Stone Tools." By C. B. Mountford. *Trans. Roy. Soc. South Australia*, 65, (2); 1941). The Pitjendadjara tribe is one of the most primitive in Australia, and among their few possessions are spear-throwers fitted with an adze stone on the end, and spears. The manufacturing process of the spear-thrower is described by the author. The tools used were natural stones selected for possessing some sort of cutting edge, but undressed. With these as the sole instruments a shaped slab was stripped from a small Mulga tree—a slow and laborious process—and the bark removed before it was taken to the camp. There the shaping and finishing took place with the help of smaller, but still unflaked, stones and finally with the aid of the adze stone of a finished spear-thrower. The adze stones themselves were merely flakes of chert with good cutting edges and were stuck into the handle end of the spear-thrower with spinifex gum warmed over a fire. When these stones became blunted with use there were some attempts to create a fresh cutting edge by tapping them with the wooden blade of a spear until miniature flakes were broken off. The throwing peg was made of wood and attached by spinifex gum to the tip of the spear-thrower and then securely bound with tendon. The stones used in these processes were all discarded and left behind, when finished with; and as such stones bear no recognizable trace of their use by human beings, a material culture such as that of the Pitjendadjara tribe might well become extinct without leaving any trace of its existence.

Pantothenic Acid in Tissue Growth

For their growth, many pathogenic organisms require pantothenate, of which there is usually more than enough in animal tissues. On the hypothesis that pantothenic acid takes part in enzyme reactions the progress of which is necessary to growth, H. McIlwain (*Biochem. J.*, 36, 417; 1942) postulates that pantothenate, to be used by an organism, combines with a particular part of it. By analogy with other enzyme inhibitors, it was expected that compounds structurally related to pantothenate might displace it from these enzymes and prevent their functioning. The inhibitions recorded for pantoyltaurine, pantoyltauramide and homopantoyltaurine show that their actions are clearly related to pantothenate and their quantitative interactions were of the character of competitive enzyme inhibitions, probably due to an analogue occupying the active centres to which pantothenate must have access for normal activity. These analogues had less affinity for the enzymes than had pantothenate and needed to be present in many times its concentration to prevent growth. Only organisms needing pantothenate were found susceptible to these compounds. Other analogues were inhibitory to several organisms not needing added pantothenate. Thus, exacting strains of *Cl. diphtheriæ* are inhibited, but not those needing added pantothenate. Such analogues may also act by interfering with pantothenate metabolism, since the latter organisms synthesized the compound.

Fishes of the Genus Bothriolepis

Walter Gross, in his work "Die Bothriolepis-Arten der Cellulosa-Mergel Lettlands" (*Kungl. Svenska Vetenskapsakademiens Handlingar*. Tredje Serien. 19, No. 5; 1941), describes in great detail two species of Bothriolepis from the Upper Devonian marls, Kokenhusen, Lettland. One of these, *B. cellulosa* (Pander), is already known; the second, *B. tuberculata*, is new and described here for the first time. Remains of both species occur in the same locality and in considerable quantity, chiefly consisting of the separate bony plates and jointed pectoral fins characteristic of these ancient fishes. The pectoral appendage, which is covered by hexagonal plates, is regarded by recent workers, including the present author, as a true pectoral fin. He suggests the possibility that the fishes here described may be only sexual forms of the same species, *B. cellulosa* being the female and *B. tuberculata* the male. The plates and fins differ in shape and markings and are beautifully preserved. The paper is illustrated by excellent photographs occupying twenty plates.

Sex Ratio in Cattle

It is sometimes believed by cattle breeders that one sire tends to produce a higher proportion of females than another, and that the sex ratio of the progeny is influenced by the age of the sire. J. W. Gowen (*J. Hered.*, 33, 299–304; 1942) has analysed the data from 3,559 births and reaches the conclusion that neither surmise is correct. Sex determination in families of cattle is at random in most instances, and the age of the sire or dam does not materially affect the sex of its progeny.

Effect of X-rays on *Drosophila pseudo-obscura*

The haploid chromosome complement of *D. pseudo-obscura* consists of a V-shaped *X*-chromosome, three rod-shaped and one small dot-like chromosomes. Nevertheless, genetical evidence indicates that the arms of the chromosomes are phylogenetically related to those of *D. melanogaster*. P. C. Koller and I. A. R. S. Ahmed (*J. Genetics*, 44, 53–72; 1942) and R. G. Helfer (*Genetics*, 26, 1–22; 1941) show that X-rays produce comparable results in the two species. The frequency of chromosome breaks per detectable changed sperm indicates that the same amount of ionization has similar effects in the two species. A considerable amount of data is given on the distribution and type of chromosome breaks and rearrangements found in X-ray induced and normal material.

Cytology of *Rhoeo discolor* and Tradescantia

P. N. Bhaduri (*J. Genetics*, 44, 73–127; 1942) has used the new cytological technique of Semmens and Bhaduri to analyse the nucleoli and secondary constrictions in *Rhoeo discolor* and several species of Tradescantia. As a result he has found that the twelve chromosomes of *R. discolor* which are derived from previous segmental interchanges show morphological differences, that non-homologous segments may be identified in otherwise homologous chromosomes, and that the number of nucleoli are increased by such interchange as well as by polyploidy. *R. discolor*, a structural hybrid diploid, has eight nucleoli in place of the more usual two in non-hybrid material. Similarly, the number of nucleoli and sat-chromosomes is higher in the species of

Tradescantia than would be expected. The size and relationships of the nucleoli are also of importance. Two homologous sat-chromosomes will give similar nucleoli, whereas nucleoli derived from non-homologous parts will probably differ. The author concludes from his analysis of *T. virginana* (4*n*) that it is not an autotetraploid, but is of hybrid origin.

Spectrophotometric Estimation of Vitamin A

J. I. M. Jones and R. T. M. Haines discussed "The Spectrophotometric Estimation of Vitamin A in Fish Liver Oils" at a meeting of the Society of Analysts and Other Analytical Chemists on November 4. The spectrophotometric estimation of vitamin A in low-potency fish liver oils is usually carried out on the extracted unsaponifiable matter, in order to get rid of irrelevant absorption at the characteristic wave-length of 325 mμ. It has previously been stated that no direct relation exists between the absorption so determined and that determined on the whole oil. Re-examination shows that there is a strong correlation between the two values for the same type of oil and that the difference is probably not due to irrelevant matter unless it be that such matter is always present in fixed relation to the vitamin A. Data for cod, shark, halibut and tunny liver oils show this correlation, but the nature of the correlation in cod and halibut is different from that in shark and tunny. There is evidence that the cause of the loss of absorption after saponification is not affected by wide variations in technique, but is related to the nature of the oil and may be connected with adsorption of vitamin by the soap formed during saponification.

Preparation of Deuterium Chloride

Although several methods have been published for the preparation of deuterium chloride DCl, they all have some drawbacks. H. C. Brown and C. Groot (*J. Amer. Chem. Soc.*, 64, 2223; 1942) find that by dropping deuterium oxide into excess of heated benzoyl chloride, the temperature being finally raised to the boiling point, deuterium chloride is evolved at a satisfactory rate. The product is analytically pure and the yield practically quantitative. The reaction occurs according to the equations:

$$C_6H_5COCl + D_2O = C_6H_5COOD + DCl,$$

$$C_6H_5COCl + C_6H_5COOD = (C_6H_5CO)_2O + DCl.$$

Hardness of Silver Alloys

The influence upon hardness of alloying with silver one or more elements which enter into primary substitutional solid solution has been studied by J. H. Frye, jun., and W. Hume-Rothery (*Proc. Roy. Soc.*, A, 181, 1; 1942). Accurate Meyer analyses made on annealed bars of vacuum-melted spectroscopically pure silver, assay silver, and on binary alloys of silver containing up to 5 atomic per cent of cadmium, indium, tin, antimony, zinc, aluminium, magnesium and gold show that in contradiction to the statements of some previous investigators, the ultimate Meyer hardness P_u increases as the grain size of the specimens diminishes. Reduction of the results to P_u values for one standard grain size enabled an accurate comparison to be made of the relative hardening effects of the different solutes. When these results are considered from the point of view of lattice distortion, it is shown that for a given atomic percentage of solute, the increase in P_u is proportional to the square of the lattice distortion for solutes in the same row of the Periodic Table. No simple relation was found for solutes from different rows of the Periodic Table, and for a given solute the relation between P_u and the composition is not necessarily simple. The conclusions are tested by experiments on ternary alloys, and data for copper alloys are discussed.

Diameters of Extragalactic Nebulæ

In an important note (*Proc. Nat. Acad. Sci.*, 28, 186; 1942), Dr. H. Shapley gives the results of a photometric comparison of spheroidal and spiral galaxies. It appears that, contrary to earlier indications, the open spirals with their widely extended arms are not appreciably larger than the structureless spheroidal forms. The new measurements, unlike the previous estimates, are based on precise microdensitometer readings taken on properly standardized plates, and reveal little difference in linear diameter between the various types of extragalactic nebulæ. The early suggestion that spiral arms are expelled dynamically from the nucleus during evolutionary development would thus seem to be premature: such features are to be regarded rather as due to a change of structure well within the main body of the system. If, as may well be, the direction of evolution is from spiral to spheroidal, then the condensed arms, supergiant stars and diffuse nebulosities of a spiral system must eventually merge into the featureless smooth form of the typical spheroidal galaxy by a process of internal readjustment and not by contraction.

Transit of Mercury on Nov. 11-12, 1940

Visual observations of this transit collected from Australia, New Zealand, Japan, the Philippines, and North and South America have been reduced and discussed by G. M. Clemence and G. C. Whittaker (*Pub. U.S. Naval Obs.*, 15, Part II, 1942). Altogether two hundred observations are combined in various ways to obtain the universal time of geocentric contacts II and III. The residuals from the indiscriminate mean are not distributed according to the normal error law, large values occurring too frequently, and the effect of excluding certain of the observations with large residuals is examined. Probable errors of ± 1·0 sec. and ± 1·2 sec. are assigned to the times of contacts II and III respectively. The adopted observed times *O* are then compared with the theoretical values *C* obtained after correcting the Tables of the Sun and Mercury for small errors of the elements. The so-called "fluctuations" *O*—*C* which result are caused by irregularities in the rotation of the earth, leading to errors in the reckoning of astronomical time. The fluctuation at contact II is 43·1 sec., while the value at contact III is 25·5 sec., the weighted mean of 36·1 sec. agreeing well with the 35·3 sec. obtained for the time of transit from lunar observations. The discordance between the two contacts indicates that the duration of the transit was 18 sec. less than the expected value, and consideration of the interval between contacts III and IV confirms this discordance. It may be attributed partially to physiological and psychological factors attending a difficult observation of this kind, but no completely satisfactory explanation can be given at present. The observations taken as a whole provide a welcome independent check on the results obtained by observations of the moon.

SCIENCE AND THE UNITED NATIONS

THE Conference on "Scientists of the United Nations and the War Effort" convened by the Association of Scientific Workers on December 5–6 covered a very wide field. Men of science must leave no doubt about their attitude to the ideologies and practices of the Nazis and Fascists. There is no question about the importance attached to science by the Nazis. Dr. Kuczynski, the famous statistician, speaking of Germany, told of the prestige there enjoyed by men of science. Speakers from Norway, Belgium and Denmark spoke of the attempts of the Nazis to impose their ideology through the universities and schools. These speakers and a Greek man of science, whose name was not published, also told of the resistance which the staffs of universities and schools are making. In Norway, for example, the universities have refused to do anything that was not legal before the invasion; the school teachers have resisted Nazi orders although one in five has been sent to a concentration camp.

The Norwegians had to face a clear-cut issue and made their choice; in Germany, as Dr. Kuczynski related, many men of science were not deliberate supporters of the Nazi regime; but, because they hoped to continue their work without interfering in public affairs, they have become active assistants of the Nazis. This leads to a point made by Dr. G. Lewi, formerly secretary-general of the Federation of Czechoslovak Chemical Industries, deputy chairman of the Association of Czechoslovak Scientists and Technicians in Great Britain, who said that men of science, on whose work the whole structure of modern civilization is built, may not remain aloof from running that civilization. If they do, they will compromise with evil and find themselves committed to the wrong side.

The part played by the people of the occupied countries in the development of science was stressed by many of the speakers. Austria, as Dr. Stock pointed out, has produced six winners of Nobel prizes for science—one per million of population; the three living prize-winners left the country after the Anschluss. Mr. Pevtich, press attaché of the Yugoslav Embassy, told of the numerous Yugoslavs who have made conspicuous contributions to science. Dr. Frankenstein, professor of international law at The Hague, spoke of the debt which German science owes to Jews, of the valuable contributions to the Allied cause by Jews in Palestine in making instruments of precision and of the chemical work of Dr. Weissman, the Zionist leader. During the civil war in Spain the encouragement given to science by the Republicans had borne fruit in the development of an extensive blood transfusion service, the first of its kind, and a new method of treating wounds. In China the growth of science has been checked by the Japanese invasion, but continues and has been concentrated mainly on problems, such as those of nutrition and agriculture, that will be involved in reconstruction.

In the selection of a person for any position, two criteria only should be considered: he should be whole-heartedly opposed to Nazism and Fascism, and he should be the best qualified to do the work involved. In a time of total war we cannot take irrelevant matters such as nationality into account. Prof. Cassin, legal advisor to General de Gaulle, was able to claim that all men of science among the Fighting French, both in Great Britain and the United States, are able to play their part to the full in the common struggle. Miss Simpson, secretary of the Society for the Protection of Science and Learning, told of the work that the Society has done, first in finding positions for refugees and later in securing the release of men of science who were interned in Great Britain; only twelve out of 526 appeals for release have been refused. Mr. T. H. Brind, of the International Labour Branch of the Ministry of Labour and National Service, spoke of the efforts made by his branch to overcome the difficulties that arise in getting full employment for alien scientific workers. However, several speakers expressed the view that adjustment is not complete. Even if no obstacles are raised by any Government Department there remains the prejudice of individual employers, which is likely to persist so long as the most ardent opponents of Nazism are labelled "enemy aliens". If the services of distinguished men of science are not used, agitation can be made and the matter is put right. But there is no machinery for redress in such a case as that of a young man who had served with the Pioneers in France, had distinguished himself in a course of training in making instruments of precision, but was then not employed on the work to which he had been trained; for fear of military discipline, he cannot let his name be used. Also, until the men of science who supported the Spanish Republic and are now in North Africa are freed, we are not using all the scientific personnel at our disposal.

Prof. S. Chapman discussed the use of scientific personnel in the War. He suggested that there is a danger of overlapping of work and that this might be avoided if a central directory be set up from which a responsible person could learn whether any question which he proposed to study was already under investigation.

At the end of the Conference the following resolution was passed:

"We, scientific workers from countries menaced or oppressed by Nazi-Germany and her Allies, assembled in London in a conference, have resolved on the following.

"We accuse Germany and her Allies of systematically destroying the scientific institutions and exterminating the scientists of the occupied countries, as an integral part of her warfare, with the intention of strangling the scientific life and culture of those countries.

"We pledge ourselves to give our best in the fight against such monstrous barbarism, and to answer to-day each new crime with a further intensification of our efforts on behalf of the suffering peoples of the world by striking harder against these enemies of mankind.

"We appeal to our colleagues on the Continent and throughout the world to increase their efforts of which we hear again and again with emotion and pride against the oppressors. Only deeds count to-day and this applies equally to the freedom loving scientists on the Continent and to ourselves.

"We warn those who to-day willingly work for our oppressors that retribution is near.

"We express our satisfaction that a very considerable number of foreign scientific workers have already found work in this country which enables them to use all their knowledge and training in the common war effort, and hope that soon all of us will have found a place where the best use can be made of our experience and willingness to serve.

"We shall work to ensure that the co-operation among the scientists of so many countries which is developing to-day shall be a model for the integration of the world scientific effort after victory has been won."

NEWTONIANISM AND SCHOLASTICISM

IN his presidential address to the annual statutory meeting of the Royal Society of Edinburgh, under the title "Aristotle, Newton, Einstein", Prof. E. T. Whittaker compared the modern revolution in physics, by which the ideas of relativity and the quantum theory have displaced those of Newtonian mechanics, with the revolution in the seventeenth century when Newtonian mechanics triumphed at the expense of Aristotelian Scholasticism. His main thesis was that the Scholastic ideas which were destroyed by the movement of which the work of Newton marked the culmination, were a perverted form of the true philosophy of Aristotle, and that the modern outlook represents a return—or at least a tendency to return—to the true Aristotelian outlook. The work of Tycho and Kepler disproved and overthrew the existing Scholastic cosmology, but it contained nothing inherently irreconcilable with the Scholastic metaphysics and might conceivably have been absorbed into the philosophy of the Schoolmen by a peaceful and conservative revolution. Actually, however, what was essentially a new metaphysic was introduced. The basic postulate of the Newtonian mechanics, in which it differed sharply from Scholasticism, was the fundamental and independent status accorded to space and time. Persistence of bodies in time and their displacement in space became the concepts to which everything in the external world had to be reduced, and bodies moved in obedience to the forces which acted on them in space and time.

A partial return to the Aristotelian view that all change is a transition between a state which is potential and a state which is actual came with the doctrine of the conservation of energy, in which force is ignored and a change is represented by a transition between potential and other forms of energy; and this tendency has more recently been emphasized by the quantum mechanics, in which the operator corresponding to classical potential energy is closely akin to the Aristotelian concept of potency. The introduction of 'minimum' principles, which culminated in 1915 when Hilbert introduced a 'world function' which determines all physical events in the universe by the condition that its integral taken over the whole of space-time is a minimum, marked another drift back to Aristotelianism, since such principles, like Aristotle's, are essentially teleological. General relativity, according to which gravitation represents a continual effort of the universe to straighten itself out, is so completely teleological that it would certainly have delighted the hearts of the Schoolmen. A free particle, in relativity theory, moves in a path determined solely by the curvature-properties of space; it is, as the Aristotelians would say, *in potency* with regard to space.

The importance of quantum theory from this point of view is that it shows that there are events in the physical world which cannot be represented on the background of space and time. Space and time must accordingly be deposed from the dominant position which they held in Newtonianism. We must begin not with space and time but with events; and the atom, which has a potency of various states, is correlated to the states as potency is to act. It endures as the atom, while it takes different states in succession. Thus, the proton and neutron are now regarded as two 'states' of a single entity, often called a 'heavy particle'. In Aristotelian terms, the heavy particle would be 'matter' and its determinations as a neutron or proton would be its two possible 'forms'. Matter is correlated to form as potency to act.

The peculiarities of modern statistical theory also are conveniently expressible in Aristotelian language. An electron can freely interchange its recognizability with other electrons; it has no sameness of being, no proper identity, no separate history. Its selfhood is merged in an electronhood which it shares with all other electrons, and which is correlated with it as potency to act. This reopens the question which engaged so much attention in the Middle Ages, regarding the nature of *universals*, or general terms, which represent the common basis of a class of individual objects.

Prof. Whittaker considers that these tendencies of modern physics should lead to more intercourse and mutual understanding between men of science and philosophers; for of all types of philosophy, the Aristotelian-Scholastic is, in its principles, the most congenial to the scientific mind. It is in a sense true that correct, even if in some respects limited, knowledge regarding physics can be combined with any view whatever on the fundamental questions of being and reality, but the effect of such segregated thinking has been to make science a departmental affair, having no influence on life and thought except indirectly through its applications. At the present time there is a movement in scientific circles aiming at securing for science a greater influence on human affairs, and even calling for a refounding of civilization on a scientific basis; but its advocates do not always understand that, as a necessary condition for the possibility of such a reform, science must be reintegrated into a unity with philosophy and religion.

ESKIMO CRANIOLOGY

THE first part of a catalogue of human crania in the United States National Museum was issued in 1924. It gave measurements of four short series from parts of Alaska. Since then the Smithsonian Institution has sent eighteen anthropological expeditions to the country, and the United States National Museum now has 2,200 Eskimo skulls, many of which are accompanied by the rest of the skeleton. The latest part of the catalogue to be issued* provides individual measurements of the whole collection of skulls, including a number for which data had been published previously. Dr. Hrdlička, the doyen of American physical anthropologists, has thus made another substantial contribution to the long list of his achievements in collecting, describing and analysing the material of his science.

For each specimen nineteen absolute measurements and twelve measurements of shape (indices and angles) are given. The set of characters which should be recorded in craniometric studies has not been standardized; and a fuller list has frequently been used. The aim in all cases has been to give a general description in metrical terms of the skull as a whole and of all its principal parts, such as the brain-box; orbits, nasal aperture and so on. Owing to the lack of international agreement, the same character has sometimes been measured by different observers in two or more ways, thus making the data less useful than they might have been with the same expenditure of labour. In spite of these drawbacks there is extensive comparative material for nearly all the measurements given in the Eskimo catalogue.

---

* *Proc. U.S. Nat. Mus.*, 91, 169–429 (1942). "Catalog of Human Crania in the United States National Museum Collections: Eskimo in General", by Aleš Hrdlička. (Washington, D.C.: Gov. Printing Office.)

Scientific workers other than anthropologists are unlikely to have any just appreciation of the scope and uses of such records. There has been no convenient digest of them, and the problems of racial history which they should elucidate apparently remain obscure. All countries in the world are represented by well-described series of skulls, and those long enough to give a reasonably good representation of a population—series comprising fifty or more fairly complete specimens of one sex, say—range from about 5000 B.C. to modern times. The peoples that have been best described in this way are the ancient Egyptian (about 5,000 specimens), Eskimo (Hrdlička, and Fürst and Hansen, 3,000), British (3,000) and Norwegian (Schreiner, 2,500). The number of Eskimos is now considerably greater than that for all other American peoples put together, if artificially deformed skulls are left out of account. It is fortunate for anthropologists that the arctic population did not adopt the unnatural practice which was common in most other parts of the continent.

Study of differences between the physical characters of Eskimo communities may be expected to throw light on the problem of the peopling of America. Dr. Hrdlička has discussed this matter at length elsewhere and he refers to it briefly in the notes appended to his new catalogue. Considered as a whole, the Eskimo population has long been recognized to be of a specialized type, as are the isolated human populations found in other remote parts of the world. The typical skull is characterized by a median ridge on the vault, and the great breadth and large size of the facial skeleton are other striking peculiarities. In spite of the basic similarity of the type throughout the population, average measurements given for local groups reveal clear differences in some characters. The cephalic index in particular makes many distinctions which are markedly significant. In general it is higher in the west and lower in Greenland, though the lowest value is for an Alaskan series which is also distinguished by being the oldest. It is assumed that the group must have spread in relatively recent times on account of linguistic and cultural similarities over all its present region. The inference is that the mixture or changes which led to physical diversity "took place not on the American continent but well back in the original habitat of the people, which doubtless was Arctic Asia". Although the evidence is fairly extensive already, it is necessary to ask for more—relating particularly to older Eskimo and related peoples—before skeletal material can be expected to reveal clearly the racial history of Eskimos in America. In considering such questions the need for fuller knowledge is constantly felt.

The cranial measurements given in the catalogue are not analysed statistically there, but they might be used to illustrate the essential nature of all modern populations of *Homo sapiens*. Variation within any subgroup is found to be very considerable, the range for any metrical character being not less than half the range for the total species. The more isolated populations, such as the Eskimo, are found to be only slightly less variable than those of Europe. Gradations within the culturally defined group, and also between it and neighbouring groups, are always observed. Anthropological data supply innumerable examples of character-gradients (or 'clines' as Huxley has recently named them), and it is owing chiefly to their existence that no agreement has yet been reached regarding the way in which races of modern man can best be defined.

Geneticists have hitherto taken little interest in polygenic characters such as cranial measurements, and it has not been shown that any skeletal characters which anthropologists might use for their special purpose are other than polygenic. A few characters of living people controlled by small numbers of genes are known, but there can be little hope of disclosing any details of the course of racial history by treating them alone. Evidence of a palæontological kind seems to be essential for that purpose. It may be anticipated that data such as those placed on record by Dr. Hrdlička will be used by future generations of anthropologists, even if they treat them by methods as yet unimagined.

G. M. MORANT.

FORTHCOMING EVENTS

Saturday, January 9

ASSOCIATION OF SCIENTIFIC WORKERS (in the Lecture Theatre of the London School of Hygiene, Keppel Street, London, W.C.1), at 2.15 p.m.—Conference on Problems connected with the Organisation, Application and Personnel of the Medical Sciences. (Chairman: Dr. D. McClean.)

Monday, January 11

ROYAL GEOGRAPHICAL SOCIETY (at Kensington Gore, London, S.W.7), at 5 p.m.—Discussion on Flying Maps.

Tuesday, January 12

INSTITUTION OF CIVIL ENGINEERS (at Great George Street, Westminster, London, S.W.1), at 2 p.m.—Sir Charles G. Darwin, F.R.S.: "The Extreme Properties of Matter" (James Forrest Lecture).

SOCIETY OF CHEMICAL INDUSTRY (CHEMICAL ENGINEERING GROUP) (JOINT MEETING WITH THE INSTITUTION OF CHEMICAL ENGINEERS) (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 2.30 p.m.—Dr. H. Ter Meulen: "The Solvent Extraction of Lubricating Oils".

ILLUMINATING ENGINEERING SOCIETY (at the E.L.M.A. Lighting Service Bureau, 2 Savoy Hill, Strand, London, W.C.2), at 5 p.m.—Mr. H. C. Weston: "Proposals for a New Lighting Code".

Wednesday, January 13

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, W.C.2), at 1.45 p.m.—Mr. Anthony Hurd: "Agriculture To-day and To-morrow", 3: "Research and the Farmer".

Thursday, January 14

PHARMACEUTICAL SOCIETY (at 17 Bloomsbury Square, London, W.C.1), at 7 p.m.—Mr. F. H. Cotton: "Synthetic Rubbers".

Friday, January 15

ROYAL SOCIETY OF ARTS (JOINT MEETING OF THE INDIA AND BURMA SECTION WITH THE EAST INDIA ASSOCIATION) (at John Adam Street, Adelphi, London, W.C.2), at 1.45 p.m.—Mr. Maurice Yeatts: "The Indian Census of 1941".

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

LECTURER IN MECHANICAL ENGINEERING in the Oxford Schools of Technology, Art and Commerce—The Chief Education Officer, City Education Office, 77 George Street, Oxford (January 17).

DIRECTOR of the National Froebel Foundation—The Secretary, National Froebel Foundation, 2 Manchester Square, London, W.1 (February 27).

CHAIR OF MINING—The Secretary, the University, Edmund Street, Birmingham, 3 (March 1).

SPEECH THERAPIST—The Education Officer, County Hall, Wakefield.

COAL CONSERVATION IN GREAT BRITAIN

IT would be difficult to overstress the importance of making the maximum use of the available coal in Great Britain; our survival as a first-class nation may indeed come to depend on the answers we give to some of the fundamental questions concerning the proper use of coal. Individually, they are well understood, and there is no great divergence of opinion as to the facts. Collectively, there is a lack of agreement as to policy, and a strange and fatal apathy on the part of Ministries and the fuel industries. This lack of understanding in the past has in no small measure brought about the present unfortunate and serious state of affairs, where confessedly we are unable to supply the consumer with our only native mineral, albeit the demand is less than in peace-time.

Certain aspects of the problems were referred to by Mr. E. V. Evans, the present technical leader of the gas industry, at a meeting of the Fuel Luncheon Club held on December 17 last. It is perhaps worth while directing attention to them, as the subject above all needs impartial discussion on a platform free from the sectional interests of the various coal-using industries.

Britain's world predominant position was built on coal; until the War of 1914–18 both coal and transport were cheap and only the very few were concerned to use coal economically. Bad habits persist, and it is a safe guess that at least 20 per cent of the coal used by industry in Great Britain in 1939 could have been saved by attention to methods of fuel economy. A committee of fuel technologists under Dr. E. S. Grumell is known to be at work to effect this saving.

The question before the public is how they shall obtain the heat, light and power they need in their daily life: from raw coal, gas or electricity? The three forms have been long competitive for the favours of the householder, and the tempting prices charged are not always fair. There can be no justification for price structures that put a tax on consumers who *must* use the commodity in order to subsidize adventure in markets that, in themselves, are uneconomic.

Surely, the various branches of the fuel industry should become complementary parts of one whole. This is the essence of the problem of co-ordination, and the solution can only be achieved by the findings of impartial judgment, sifting and balancing the advice of experts. The fuel industries themselves should be preparing for such comprehensive co-operation, which indeed has been largely achieved in certain American cities, but so far there is no sign of such vision in Great Britain.

The householder of the future will require to use both gas and electricity and perhaps some solid fuel for water and space heating. The old-fashioned coal fire grate, using raw coal and sending all the tar products and most of the heat up the chimney, is an anachronism. Surely it should be forbidden as a wasteful apparatus under the new fuel order announced on December 28, for only some 20–25 per cent of the heat in the coal reaches the room. It is responsible also for the smoke pall, for fogs and for the decay of stonework, metal and textiles. Until November 11 last, many of the present generation had never seen a London fog and realized what burning raw coal involved. It is criminal also to waste the raw hydrocarbon material present in coal tar. Great Britain has no native oil, a handicap the extent of which we have yet to realize, and it should be insisted that every ounce of tar is recovered and used as the raw material for motor-fuel and chemical industries. Perhaps the day may come when all coal, whether used for domestic or industrial purposes or for making electricity, is carbonized before use. Petroleum may well become scarce or we, as a nation, so poor that we cannot afford to buy it.

Light will be supplied by the electrical industry and should become cheaper, better and capable of decorative development as the lamp improves. Power applied to small units is also a matter for electricity. The cooking and individual heating load is claimed by gas, and the share that electricity is to take requires settlement. Water heating and central heating are best done with coke, for which they provide a valuable outlet. Both gas and electricity claim to heat small quantities of water.

It is quite clear that from the scientific and national point of view the burning of raw coal by the domestic consumer should be discouraged: a point not previously mentioned is that the transport and delivery of solid fuel to each household and the collection of ashes are wasteful factors. Rubber, petrol and man-power are scarce now, but however plentiful they may become they should not be wasted.

Both gas and electricity are 'on tap' in the home; the onus of maintaining an efficient load factor is thrown on the companies. The annual hourly load factor of the gas industry, that is, the relation to the plant required to meet the maximum demand, is of the order of 17–20 per cent. Fortunately, the provision of the gasholder makes it possible to even out the load to 50–60 per cent. The load factor of the electricity companies is 30–35 per cent: they can store steam but not electricity.

Both industries seek to obtain off-peak loads, presumably each from the other. Both have made great strides in economic production. Since 1916 the consumption of coal per horse-power hour for power has dropped from 5–7 lb. to 1¼ lb. The gas industry has increased the thermal efficiency of its process to about 80 per cent and increased the total amount of heat supplied by 13 per cent in the last eighteen years in spite of competition by the electrical industry. The replacement of the coal range by the gas cooker has involved a saving of some 15 million tons of coal a year, besides an enormous relief to the housewife.

As regards the future, the coal industry is endeavouring to design appliances that shall burn coal without smoke; the gas industry is preparing to demonstrate how greatly the interests of the nation and of the consumer will be served by the extended use of gas for space heating and water heating; and the electrical industry, always growing more efficient, is interested to take over such proportion of these loads as can be supplied remuneratively.

Some measure of guidance and of collaboration is necessary. In this, coal conservation must be included as the predominant factor. The appliances and methods that were in common use before the War and are in use to-day show striking differences in the amount of coal that has to be consumed to give *equivalent service* by different methods. According to Mr. Evans, for most domestic uses gaseous fuel shows a saving of some 40 per cent compared with either raw coal or electricity. Clearly we must try to establish and work to a sane national fuel policy, so that the resources of material and man-power in Great Britain are not wasted.

MEDICINE FOR PHILOSOPHERS

Physics and Philosophy

By Sir James Jeans. Pp. vii+222. (Cambridge: At the University Press, 1942.) 8*s*. 6*d*. net.

IF Sir James Jeans finds difficulty in defining philosophy (p. 16), there is no doubt of his qualifications for the task. Emerson, in his essay on Plato as a "representative man", defines philosophy as the account which the human mind gives to itself of the constitution of the world. It has been given to Jeans to participate effectively in our quest for the "constitution of the world"; as physicist, as mathematician, as astronomer, as cosmologist, he has opened windows on Nature—on the origins of planetary, stellar and nebular masses and on the interplay of matter and radiation. Now he attempts what he has earned the right to do: he speaks to us his account of the nature of reality, his views on materialism and what he calls mentalism, on determinism and free-will.

If we define the aim of science, including all utilitarian and humanitarian applications, as the endeavour to live the good life and to see into the mind of God, then at least part of that aim is realized when a mature man of science and thinker approaches the fundamental problems of philosophy by the path of mathematics and physics; and in fact without that background the discussion of philosophical problems tends to remain verbal and scholastic. It is, of course, sadly true that whereas we have had our poet and our man of science with the unmistakable characters of universality and agelessness—our Shakespeare and our Newton: we still await a modern *universal* philosopher, a thinker fully equipped as mathematician, physicist, biologist and psychologist, a new Aristotle. Sir James Jeans modestly states that his acquaintance with philosophy is simply that of an intruder, without any authority on questions of pure philosophy. Nevertheless he gives the pure philosopher a good deal to think about.

Perhaps the pure philosopher will wince most under the thrusts which Jeans gives him in the chapter entitled "The Two Voices of Science and Philosophy". While much of the book, as a survey of recent physical thought, is necessarily not new, in these sections Jeans has something vivid, pertinent and new to say to philosophers; and they may be considered as constituting Jeans's riposte (and an effective riposte they are) to the criticisms which have been made on him by professional philosophers. He analyses the relation between science and philosophy in terms of differences of language, differences of idiom and differences of method. His main reason for the differences of language is that philosophy "tends to think in terms of facts as they are revealed by our primitive senses, while science thinks of them as they are revealed by instruments of precision"; he illustrates this, in more than one part of the book, by a most engaging account of the differences between what the philosopher thinks he means by 'red' and 'redness' and what the physicist means.

Jeans is still more to the point in his account of the philosopher's *idiom*. He gives three types of this. First, "the philosopher usually thinks in terms of qualities, the scientific man in terms of quantities". Secondly, he accuses philosophers of "depicting the world entirely in black and white, and so ignoring all the half-tones, gradualness and vagueness which figure so prominently in our experience of the actual world", and illustrates by the law of the excluded middle, which has so devastated logic. (A pure mathematician might, however, have something to criticize in Jeans's statement that a fallacy lies in the supposition that quantities can be sharply divided into finite and not-finite.) Lastly, he accuses the philosopher of over-simplification. I confess I found myself uneasy on this point, for though Jeans is happy in his examples, as usual, he must be well aware that progress in a *scientific* problem nearly always attends on the right kind of simplification and idealization; in fact, it may be said that the role of mathematical physics is to make self-consistent statements about non-existent entities. As regards differences of method, Jeans criticizes the philosopher as being more *atomistic* in his thought than the scientific man—treating time as a collection of instants, and so on. Jeans is not, however, fortunate in his example of the scientific man seeing Nature as a theatre of *continuous* change, "as a *cinematograph* show rather than as a series of magic-lantern slides"; indeed, he later dwells on the snare of mistaking apparent continuity for genuine continuity, instancing the staircase at 45° with very small steps, which will always support a particle in equilibrium.

On the science of philosophy, Jeans is good; on the philosophy of science he is less good. In a sentence which I do not understand, Jeans says: "The métier of the philosopher is to synthesize and explain facts already known". Does Jeans exclude from the philosopher's province that of *criticism*? It seems to me that one of the principal differences between philosophy and science is that the problems of philosophy are permanent whereas the philosophical conclusions of science are ephemeral. Recently, indeed, physics has changed almost unrecognizably every twenty years or so, not only in the scope of its content but also in its conclusions about itself. What right have we to regard the present position in physics with the complacency which Jeans almost habitually assumes towards it? He attributes to it a degree of perfectibility which philosophical history teaches can be assigned to no construction of the human mind. In his concluding sentence he admits that the quest, and not the knowledge itself, gives the greater interest to thought; but where, in this volume, is that ceaseless interrogation of current conclusions which it should be the aim of a critical philosophy to conduct?

I fear that professional philosophers could find much to criticize in the current philosophy of physics, if it were wholly as given in this volume. A few instances are all I have space for.

First of all, for the honour of nineteenth century science, I must correct an unexpected slip on Jeans's part. He says that the mere permanence of the atom showed the need for a revision of the classical mechanics, for (p. 124) "the constants known to the classical mechanics cannot be combined to form a length at all"; surely e, m and c combine to give e^2/mc^2, which is not only of the dimensions of a length but also gives the order of magnitude of the radius of the electron in interaction with a proton, a length which is fundamental in recent electrodynamics. That the radius of the atom is of a different order of magnitude no more implies of itself a new constant of Nature than the size of the living cell.

Jeans repeatedly (pp. 139, 193, etc.) speaks of "ordinary physical" space and time as something quite familiar and distinct from the conceptual spaces of the mathematician; in a fundamental analysis we choose some particular conceptual space as convenient for particular physical phenomena. He speaks of "the special properties of *this particular world*" (p. 49) as though philosophically it were legitimate to speak of the totality of things as if these were but a part of a wider whole. On pp. 17 and 96 he describes the world as *unintelligible*, on pp. 82 and 174 he describes it as *rational*; whatever meanings I allow these two attributes, I find them contradictory. He is sweepingly condemnatory of older "aether" theories; but he blandly accepts the four-dimensional space-time "continuum" (a disguised aether) and speaks of Nature's "dodging action at a distance" by "making gravitation act on space" (p. 119), and though he admits that this only "postpones the difficulty" he does not take it up again. He never questions the conservation laws, although that of energy has led to the introduction of an unobservable particle—the doubtful neutrino; and although the conservation of linear momentum, applied to a set of discrete particles, is not without difficulties in the light of the theory of relativity.

Again, Jeans considers electric and magnetic forces as not real at all, but mere mental constructs. One may agree with this, but not for the reason given by Jeans, that they "do not even pass the test of objectivity" (p. 200); a vector or tensor is none the less 'real' because its components depend upon the axes chosen, and if we have to accept a four-dimensional continuum as real, why not a four-vector? He does not criticize the classical theory of relativity on its vulnerable ground, namely, that it ignores the uni-directionality of time for each observer. Lastly, he commits a philosophical error in the clause, "If we know nothing about a particle except that it exists" (p. 201), for we cannot *know* of the mere existence of a particle from our own perceptions; observation of the kind considered in physics could not merely indicate the quality 'existence'; it must make some numerical assertion about that existence.

In a lighter vein, Jeans says he is not clear about $2 + 2 = 4$. He seems to think that because two sea-serpents plus two sea-serpents might remain only two sea-serpents (perhaps by cannibalism?), therefore he is entitled to throw doubt on the proposition $2 + 2 = 4$ (p. 46). Surely this is a proposition not of physics but of pure mathematics, and such propositions, he admits (p. 49), are universal.

Jeans comes to no final verdict, but inclines to the view that phenomena do not form reality but are only an extrusion from a deeper-lying substratum, not in space-time. This, he thinks, may resolve the apparent conflict between causality and indeterminism. He might well here accept a spoonful of the medicine he hands out to philosophers: the answer to that conflict must surely be that it is falsely couched in terms of conflict, that we must not consider it as an antithesis of black and white but reconsider it in greyer shades, and that what mathematical philosophy might reasonably be asked for is a calculus which intervenes between classical causation and the nescience of probability theory.

E. A. MILNE.

NUMBERS, NUMBERS, NUMBERS

Guide to Tables in the Theory of Numbers

By Derrick Henry Lehmer. (Bulletin of the National Research Council, No. 105: Division of Physical Sciences, Committee on Mathematical Tables and Aids to Computation, Report 1: Report of the Sub-Committee on Section F, Theory of Numbers.) Pp. xiv+177. (Washington, D.C.: National Academy of Sciences, 1941.) 2.50 dollars.

THE U.S. National Research Council has embarked on the ambitious venture of producing a series of reports dealing with mathematical tables and aids to computation in every branch of mathematics, as well as in allied and associated subjects. All the reports are to take fully into account what is important in current research, and are to be written in such a way as to be intelligible for the most part to specialists in other fields. The reports are prepared primarily for scholars and others active in scientific work.

The present report, which is due to D. H. Lehmer, is the first of the series, and it sets a high standard indeed for the others. The book consists of three parts, of which the first is a descriptive survey, or rather some account of what the tables contain, often with a considerable amount of useful explanatory matter. This is written so as to be helpful to those most likely to consult the tables, including the amateur mathematicians who are more often attracted by number-theory than by other branches of mathematics.

The second part contains a bibliography giving the sources of the tables quoted in Part 1, and also some indication of the libraries in the United States and Canada where they are available. The third part contains a list of errata found in the tables, many by Lehmer himself.

Lehmer has produced an eminently readable and serviceable volume. He has brought to bear on his task more than a wide knowledge of number-theory and skill in calculation. Nothing appears to have been omitted that will conduce to ease in consulting the book, whether it is a question of arrangement, of explanation, or of reference. All arithmeticians are sure at some time or other to need this book and to have every reason to be grateful to him.

The volume suggests some reflections. In no other part of mathematics do tables of some kind play so important a part in research. This is not surprising since numbers are so fundamental in the mental development of man. Even in an early stage of civilization, the least curiosity or the slightest manifestation of intellectual activity led to the investigation of the properties of numbers. Then followed experiments with numbers and the gathering of numerical material. This led to empirical and inductive conjectures, some of which were proved in due course; and for many years practically every theorem in number theory was suggested in this way. There is ample evidence to this effect in the works of the great mathematicians Euler and Gauss, both of whom were renowned for their powers of calculation. Those conjectures, however, which were not soon proved, led to the further accumulation of numerical results used in testing the conjectures. Many results, the proofs of which now seem very simple, were very difficult to prove at first, and hence the great variety of tables in number theory.

The reader may be curious as to what has constituted the life-blood, so to speak, of arithmeticians. A glance at Part 1 of this book is most instructive, and I note a little of what is immediately intelligible. Probably the most useful are factor tables. In the early part of this century, D. N. Lehmer, the father of the present author, constructed a factor table for the first ten millions (and a few more numbers) which was published in 1909. No error has as yet been found in the 2,372,598 entries of Lehmer's table. Among the most interesting factor tables are those associated with the Mersenne numbers and giving the factorization of many numbers of the form $2^p - 1$, where p is a prime less than or equal to 257.

Prime numbers have long occupied the attention of arithmeticians, and there are many tables of various kinds. Empirical evidence suggested to Legendre and Gauss that the number of primes less than a given large integer x was asymptotically equal to $x/(A \log x + B)$, where A and B are certain constants. This was proved with $A = 1$, $B = 0$ by Hadamard and De La Vallée Poussin independently in the early 1890's. D. N. Lehmer utilized his factor tables to publish in 1914 a list of prime numbers up to a little more than ten million.

The Pellian Equation $x^2 - Dy^2 = 1$ or -1, where x, y are to be integers, is an equation famous in the history of mathematics since the seventeenth century. The first sizable table was published by Legendre in 1798 and went as far as $D = 1003$. It was continued by Bickmore up to 1500 and published by Cayley. Finally Whitford published in 1912 solutions for $1500 < D \leqslant 1700$, and D. H. Lehmer has produced a manuscript containing the solutions for $1700 < D \leqslant 2000$.

Among the tables which proved particularly useful for theoretical investigations were those dealing with quadratic forms in two variables; for example, the tabulation of non-equivalent quadratic forms $ax^2 + 2bxy + cy^2$ with given determinant $d = b^2 - ac$. This was started by Legendre, but extensive tables were computed by Gauss, the founder of the modern theory, and published after his death.

The study of the important partition function $p(n)$ was also materially influenced by tables. $p(n)$ is the number of solutions in positive integers of the indeterminate equation $x + 2y + 3z + \ldots = n$, and was introduced into analysis by Euler, who tabulated it up to $n = 59$ some time about 1750. This table was not extended until 1917, when the researches of Hardy and Ramanujan led to MacMahon's calculation of $p(n)$ for $n \leqslant 200$, and this was exceedingly important in the interpretation of new results for $p(n)$.

Goldbach's conjecture that every even number greater than 2 is the sum of two primes was propounded nearly two centuries ago. No proof of this has been found, though its truth is supported by many tables.

Finally, we may refer to tables dealing with

Waring's problem and in particular with cubes; for example, the conjecture, proved only recently by Dickson, that every positive integer is the sum of at most nine positive integral cubes. It is thought that only four cubes are required for sufficiently large numbers, but this has not been proved. Many tables give the least number of positive cubes required to represent a number n. Thus in 1835, Zornow gave tables for $n \leqslant 3000$. These were recomputed and extended by Dase to $n \leqslant 12{,}000$ and published by Jacobi in 1851. These were extended by Sterneck to $n = 40{,}000$ and published in 1903. Finally, an unpublished manuscript of Dickson continues the table to $n = 270{,}000$. Other tables of cubes have been computed by Western. Despite all these tables, it is not yet known whether every integer can be expressed as a sum of four cubes of integers of any sign (though the question is very simple with five). I venture to suggest, however, that tables will play a prominent part in answering the question.

L. J. MORDELL.

BRITISH ARCHÆOLOGISTS IN GREECE

The Annual of the British School at Athens

No. 38: Session 1937–38. Pp. xii+154+35 plates.
No. 39: Session 1938–39. Pp. viii+112+30 plates.
(London: Macmillan and Co., Ltd., 1940, 1942.) 42*s.* net each.

THESE handsome volumes render account of the archæological work of the British School at Athens in the two seasons preceding the outbreak of war, and illustrate its range and high standards of scholarship. They differ in contents, the earlier presenting a part only of the results of a single series of excavations; the later, seven shorter papers, of which only one is an excavation report, and the others are studies of inscriptions, museum collections, and the like.

The exploration of the upland plain of Lasithi in east-central Crete was undertaken by the late J. D. S. Pendlebury, with the assistance in 1937 of Miss Money Coutts and Miss Pascoe. In this secluded region the best-known site, the cave sanctuary of Psychro, was visited by Sir Arthur Evans in 1895, and explored by the British School in 1901–2. As its contents ranged in date from early bronze age to archaic Greek times, it was evident that the settlements in the plain below it had likewise a long history, spanning the cultural gulf between Minoan and Hellenic culture, and offering exceptional opportunity for examining the many problems, archæological and historical, of the transition. To this Pendlebury had already devoted several seasons, and the results here described are the reward of a type of intensive regional exploration which will supersede the older raids on isolated and fortuitous objectives, wherever local conditions are favourable, and mature students can be found to devote more than a single season to a 'dig'. To provide the means for such intensive study and prolonged acquaintance is one of the major preoccupations of the British School and similar institutions everywhere. The days of the 'wandering scholar' are not over, by any means—wide and planned travel remains a first pre-requisite—but reconnaissance is only the prelude to excavation as an instrument of scientific advance.

Main results of the work in Lasithi are the discovery of other cave sanctuaries, like Psychro; the examination of a mainly bronze age settlement, Kastellos Tsermiádhon, occupied from Neolithic to Middle Minoan times, when it seems to have been deserted except as a cemetery; and the revelation at Karphi, a strong natural fortress on the edge of the plain, of a 'city of refuge' established when the old Minoan regime collapsed at the beginning of the iron age, and maintained throughout the 'intermediate period', which seems to have ended about 900 B.C. Then, the open country being safer, the inhabitants of Karphi descended once more from the 'peg' to which they had clung for two centuries. Truly Aristotle was not far wrong when he described the Greek city-state as "coming into being to keep men alive", a *pis aller* to which Cretans have recourse again to-day. Here is a real piece of historical spadework, of which the intricate detail must be sought in this well-written record, fitting memorial of its brave and brilliant author, who was wounded in Crete in 1940, and thereafter murdered by Germans.

Two of the papers in volume 39 are of exceptional interest. Miss Benton's excavation of the cave-sanctuary on Polis bay in Ithaca is part of a concerted exploration promoted and largely maintained by the late Lord Rennell of Rodd, whose judgment as scholar and yachtsman was that the topographical descriptions in the "Odyssey" deserved archæological verification. In previous seasons Mr. W. A. Heurtley, then assistant director of the British School, detected the remains of a bronze age fort and habitation at Pelikáta, commanding all landing places in the northern half of the island, thus confirming the place-name 'City Bay' (Polis) for a cove practically uninhabited in classical or medieval times. On the steep side of Polis bay Miss Benton explored a cave-sanctuary the vogue of which began in the bronze age, and was continuous until late Greek times; and one of its votive offerings was inscribed in Greek "a prayer for Odysseus". In earlier Hellenic times a great dedication of bronze tripod-cauldrons attested the fame of the little shrine, whither gifts came from so far afield as Ionian and Italian cities.

Here, then, was the continuous vehicle of tradition from the days of the bronze age post above the bay to those of the poet of the "Odyssey". The argument is simple and conclusive: only Teutonic perversity could have argued that because Ithaca is now called Ithaca, Homeric Ithaca "must have been" somewhere else: *Sagenverscheibung* most pedantic. But the work was not easy. The cliff had subsided since ancient times, and Miss Benton had to grope for her tripods, knee-deep in a tideless sea.

During Schliemann's excavation at Mycenæ in 1877, a group of gold objects was found, outside the stone-built 'Circle', which commemorated the famous 'shaft-graves', but obviously belonging to the same culture as their splendid equipment. When the British School made supplementary excavations around the 'Circle', it became clear (as Schliemann himself supposed) that these objects came from another 'shaft-grave' which had been broken up when the 'circle' was constructed, or by a drain built soon after. Miss Helen Thomas now shows, by minute study of the gold-work and the site, that these treasures stand rather late in the 'shaft-grave' series, that they were looted from a grave of that period, but that what was found in 1877 had been hurriedly re-buried in the grave itself when the rest of the treasure was removed.

Among the other contributions, a report on the various charcoals found in Miss Winifred Lamb's excavation of an early bronze age settlement at Therm in Lesbos illustrates the great variety of calls on experts in other sciences, which are unavoidable in archæological work; and also the return which excavation can make, in evidence for the history of vegetation. Miss Bancroft, of the Imperial Forestry Institute at Oxford, identifies no less than seven varieties, including both vine and olive (not demonstrably cultivated) and a climbing plant like Salacia which does not seem to grow now in Lesbos.

JOHN L. MYRES.

SEASONAL RHYTHMS IN MAN

Seasonal Influence on Growth, Function and Inheritance

By A. B. Fitt. (New Zealand Council for Educational Research, Educational Research Series, No. 17.) Pp. xiii+182. (Christchurch, Auckland and Wellington: Whitcombe and Tombs, Ltd.; London: Oxford University Press, 1941.) 10*s.* 6*d.* net.

THE physiological cycles of lower mammals in relation to the seasons of the year must have been included in the earliest biological knowledge acquired by primitive man when he first began to observe the processes of Nature. On the other hand, corresponding functional rhythms in man are too inconspicuous to have attracted attention without deliberate inquiry. Even so, it has for a long time been recognized that the rate of growth of the human body is to some extent influenced by, or correlated with, the seasons. Data bearing on this question, partly the result of personal observations, have recently been collected and analysed by Prof. A. B. Fitt, and published by the New Zealand Council for Educational Research. These data include the weight and height increases of school-children, the weight increases in tubercular patients, seasonal fluctuations in muscular capacity, mental ability, mortality, suicide and delinquency, and the relation of weight, height, intelligence, etc., to the month of conception. The last subject is unfortunately included by the author under the general heading of "Seasonal Influence on Inheritance", a phrase which is clearly misleading, for the relevant data do not include a correlated study of the corresponding characters in the parents.

Prof. Fitt finds that the weight increase in children is at a high level in the autumn-winter half of the year and continues at a fairly low level in the spring-summer half. On the other hand, the height increase maximum coincides with the weight increase minimum. There is a phase of high vitality in the autumn, followed by a phase of low vitality in the spring. Rates of crime and delinquency are relatively low in the autumn and winter and high in the spring and summer, while the rates for suicide and insanity are similar to those for crime except that, instead of diminishing at the end of spring, they increase up to midsummer.

In considering the possible explanations of these periodicities, the author concludes that they reflect fluctuations in the 'stress' to which the growing individual is exposed at different seasons of the year. However, he does not define clearly the meaning of his concept of 'stress', and the reader gets the impression that this is little more than a convenient term for expressing the general results of the investigation. As to the cause of the periodical variations in 'stress', the author is strongly inclined to the view that they have an endogenous origin, that is to say, they are the expressions of an internal rhythm, possibly related to fluctuations in endocrine activity, rather than the result of environmental factors of temperature, light, humidity, diet, and so forth. Here many readers will find that Prof. Fitt proceeds much too fast for their liking. The discussion on hibernation in mammals and its relation to endocrine functions will possibly appear too indirectly related to the main thesis of the book, and the author seems too lightly to dismiss the influence of environmental factors as of little significance. We would suggest, in this connexion, that reference might appropriately have been made to the extensive studies on the effect of light on pituitary activity and thereby on general behaviour, particularly in birds and lower mammals. We note, also, that no reference is made to the detailed studies which have been made on seasonal differences in the growth of separate tissues such as the hair and nails. But perhaps it is a little ungrateful to point out such omissions, for undoubtedly Prof. Fitt's book is a valuable compendium of data of great importance to the sociologist and educationist.

The author concludes by briefly discussing some important implications which arise from his work, particularly in relation to the adjustment of the educational year to the seasonal rhythm of bodily functions. Even if it should be argued that the further analysis of more extensive data will be required before they can be confidently applied to educational policy, it will be agreed that Prof. Fitt has clearly pointed out the need for future research along these lines.

LAPLACE TRANSFORMS

The Laplace Transform

By David Vernon Widder. (Princeton Mathematical Series.) Pp. x+406. (Princeton: Princeton University Press; London: Oxford University Press, 1941.) 36*s.* net.

THE theory of Fourier integrals arises out of the elegant pair of reciprocal formulæ

$$f(x) = \frac{1}{\sqrt{(2\pi)}}\int_{-\infty}^{\infty} F(y)e^{-ixy}\,dy,$$

$$F(y) = \frac{1}{\sqrt{(2\pi)}}\int_{-\infty}^{\infty} f(x)e^{ixy}\,dx,$$

in which either of the functions $f(x)$ or $F(y)$ may be arbitrarily given, and the other is then determined by it, and also forms the kernel of an integral formula which represents the given function. The Laplace formula is

$$f(s) = \int_{0}^{\infty} e^{-st}\,\phi\,(t)\,dt,$$

or the limits may be $(-\infty, \infty)$, with a corresponding reciprocal formula. The two theories are really the same, since one set of formulæ can be reduced to the other merely by a change of the variable.

When I commenced analysis some twenty years ago, the theory of Fourier transforms was little more than a footnote to the more popular theory of Fourier series. There were the classical applications to the solution of partial differential equations, such as those given in the book of Riemann-Weber. But what is now considered as the fundamental theorem of the subject, that if $f(x)$ has its squared modulus integrable over $(-\infty, \infty)$, then so has $F(y)$, had only just been proved by Plancherel. Little use had been made of the theory in its up-to-date form, and no books on the subject existed.

To-day the position of Fourier integrals might be compared with that of power series in the old theory of functions. A Fourier integral is the natural way in which one represents functions of certain classes, and the various generalizations of the integral, such as the Stieltjes integral, enable us to bring wide classes of functions within the scope of the method.

The subject of the present book is the same as that of a book by G. Doetsch in the Grundlehren der mathematischen Wissenschaften series, but the details are widely different. This work begins with a very useful detailed account of the theory of Stieltjes integrals, and the Laplace integral is mainly considered in the Stieltjes form

$$f(s) = \int_0^\infty e^{-st}\, d\alpha\,(t).$$

The theory of the representation of a function of a complex variable s in such a form is established. Applications are then made to moment problems, to the theory of absolutely and completely monotonic functions, to Wiener's general Tauberian theorems and the prime-number theorem. After a discussion of the bilateral Laplace transform (with limits $-\infty, \infty$) applications are made to the 'Stieltjes transformation'

$$f(x) = \int_0^\infty \frac{\psi(t)}{x+t}\, dt$$

and related topics. Much of the analysis is the author's own original work. This very lucid presentation of it will be welcomed by all students of the subject.

E. C. TITCHMARSH.

THE NEW BIOLOGY

Molecular Films, the Cyclotron and the New Biology

Essays by Hugh Stott Taylor, Ernest O. Lawrence and Irving Langmuir. (Rutgers University Publications of the One Hundred and Seventy-fifth Anniversary Celebration, No. 4.) Pp. v+95+24 plates. (New Brunswick, N.J.: Rutgers University Press, 1942.) 1.25 dollars.

THERE are many ways of celebrating an academic anniversary, though some, alas! are not available in war-time. The method adopted by Rutgers University to honour its one hundred and seventy-fifth anniversary has been to commission and publish a series of essays by men of distinction in science and learning.

One is always glad to hear from Dr. Irving Langmuir on any topic he chooses to handle; in this instance it is molecular films. He has a way of making profound things seem obvious which is very flattering to the intelligence of the reader. The remarkable results which are still flowing from the Berkeley cyclotron keep one on the *qui vive* for any new account by its inventor and director, Prof. Ernest Lawrence. There is no doubt that a collection of essays gains much if there is some more vital connexion between them than the mere fact that they happen to be enclosed in the same covers. The theme of the present volume is the interrelation of the physical and biological sciences in the past, and the hopefulness for mankind of still closer co-operation between them in the future. The theme is stated explicitly by Prof. H. S. Taylor in his introductory essay on "Fundamental Science from Phlogiston to Cyclotron". "To go forward to meet the years of difficulty ahead," he writes, "we shall need the effort of all men of good-will among whom the scientist, by the nature of his calling, must certainly be numbered. The processes of mutual co-operation and assistance among the individual sciences must be multiplied. The isolation of one science from another must become progressively less and less even though the degree of specialization within a science becomes perhaps greater and greater. This calls for an increasing breadth of culture and of education among the scientists." Prof. Taylor's excellent survey of the history of science during the past 175 years is in the nature of a commentary on this theme. The essays by Dr. Langmuir and Prof. Lawrence provide, in fuller detail, forcible illustrations of the argument from science actually in the making.

In his essay on "Molecular Films in Chemistry and Biology" Dr. Langmuir deals mainly with the chemical aspect, contenting himself with pointing out that the method is one which must throw very considerable light, when properly applied, on many of the obscurer problems of biology. He is offering a tool which the biologists have still to make use of. The cyclotron has already captured the imagination of the biologists, particularly of the medical biologists, and Prof. Lawrence has much progress to report on subjects as diverse as the treatment of cancer, the action of enzymes and vitamins, the secrets of photosynthesis, and the digestion of proteins.

The book is not addressed specifically to the general reader—it assumes some acquaintance, at any rate, with scientific nomenclature—but it should not be difficult reading for anyone who takes an intelligent interest in the progress of the sciences. Biologists, both medical and lay, to whom it is particularly directed, should find it both fascinating and stimulating; though whether they will consider the subtitle of the volume, "The New Biology", to be, as yet, quite justified remains to be seen. That the new weapons now being forged will bring, as Prof. Lawrence predicts, "exciting new pioneer days of discovery" in biology as well as in physics and chemistry is already certain.

This brief review has, I fear, done rather scant justice to Prof. H. S. Taylor's admirable opening essay. By way of *amende*, I quote its concluding sentences. "The modern world, says Maritaine, by which I mean that world which is coming to an end before our eyes, has not been a world of harmony between forms of wisdom, but one of conflict between wisdom and the sciences, and, he adds, it has seen the victory of science over wisdom. Have not we scientists, so to speak, to surrender that victory? We shall not yield our energy, our courage, our diligence in the search of truth. We shall but renounce the primacy to which a sick world has thrust us; and we shall gain by our renunciation. In the free world to which we still dare to look forward, with the soldiers and statesmen, artists, philosophers and priests we shall integrate our scientific skills with the social and spiritual aspects of human life and nature. Let this, we may pray, be an horizon not too far distant."

J. A. CROWTHER.

POLYGENIC BALANCE IN THE CANALIZATION OF DEVELOPMENT

By DR. K. MATHER

John Innes Horticultural Institution, Merton, London

ONE of the greatest differences between genetics to-day and genetics of thirty years ago is to be found in the changed attitude of geneticists towards the relation of a gene to the character, or characters, which it affects. The early geneticists equated a given gene difference to the character difference from which its existence was inferred. The gene for tallness in peas gave tall peas and its allelomorph gave short peas. The significance of the fact that a tall pea, as Mendel himself observed, could be 6 ft. tall or 7 ft. tall or of intermediate height was overlooked; the variation in height of tall peas was not discontinuous and so was not obviously attributable to a gene or genes detectable by the Mendelian technique. Such an attitude is very understandable because the success of Mendelian analysis lay in its concentration on simple character differences, in its exclusion of all extraneous variation from account. But this outlook carried with it disadvantages too, for concentration on discontinuous variation in experiment led easily to the assumption that the variation by which evolutionary changes were effected was just as sharply and obviously discontinuous. The outcome was the mutation theory of evolution on one hand and the presence and absence theory on the other.

It is true, of course, that after, say, 1906 all geneticists were familiar with the fact that the expression of one gene could be contingent on the presence of a given allelomorph of another gene. Bateson[1] gives an extensive account of the inheritance of complementary and epistatic genes, but the observations could be interpreted so easily in terms of the presence and absence theory that they did little or nothing to shake the idea of what we may perhaps call the characteristic expression of the gene.

Soon, however, several lines of approach led geneticists to doubt the validity of this simple interpretation and finally to abandon it altogether. Four deserve special mention. Bridges[2] found that the inheritance of sex in *Drosophila melanogaster* could not be explained in terms of the presence or absence of any given gene or genes. The numerical relations, or, as he called it, the balance, of the chromosomes, present in all flies, determined whether they would be supermale, male, intersex, female or superfemale. A little later Fisher[3] pointed out that the genes controlling mimetic patterns in insects must be presumed to have been given their special properties by the selection of other genes. He later concluded that even the dominance relations of one gene must be dependent on other genes of the nucleus, and the existence of such dominance modifiers has since been amply verified by experiment. Muller[4] showed that the expression of sex-linked genes must be supposed to be subject to genetical adjustment, for otherwise no reasonable explanation could be given of the equality or near equality of expression of these genes in the two sexes. There exists a means of dosage compensation. Finally, Timoféeff-Ressovsky[5] was able to demonstrate, by direct experiment, that the expression of certain genes in Drosophila was modified by the action of other genes. The dependence in expression of any given gene on the other genes of the nucleus, on the genetical background as it is often called, is thus beyond doubt.

This change of ideas concerning the relation between gene and expression has had a profound effect on the attitude of geneticists towards evolutionary change, as recent writings have shown. Ford[6], Muller[7] and Huxley[8] have especially developed the application of this new outlook to the better understanding of adaptation and evolution. It is not without significance that the rise of the idea of the dependent action of genes has progressed side by side with a return to Darwinism and the abandonment of the mutation theory.

Some further consequences of this view have now been discussed by Waddington[9]. In particular, he points out that the dependence in expression of one gene on the action of others permits a more co-ordinated response of the organism to its environment. Using both embryological and genetical data he shows that development may be regarded as canalized, that is, that although an organism may follow any one of a number of developmental paths, it is difficult to make it develop along lines intermediate between these possibilities. In genetical language, the integrated genotype acts as a buffering system, in such a way as to limit the variation of the organism's response to environmental fluctuations. Major or switch genes may determine which of the paths will be followed, but systems of other genes, the buffering action of which can be adapted by natural selection, will delimit the possible paths with greater or less precision. The switching action may have originally depended on environmental differences but, as Waddington points out, this function can, and generally will, be transferred ultimately to a genetic difference, and in this way will come to operate with greater efficiency and regularity.

Now, although the distinction between switch genes and buffer genes must not, for reasons which we shall presently discuss, be pressed too far, it is clear that the parts they play in controlling development are quite different. We may then expect them to be detected in different ways, to have effects of different magnitudes and to respond differently to selection. Genetical evidence is now available on these points and with its help we can form a clearer picture of how such co-ordinated systems arise and of how they change under the action of natural selection.

The familiar genes of genetical experiment fall into the category of what we have called switch genes. They are not usually known by this name, being more often called major mutants or qualitative genes, to distinguish them from the minor genes controlling quantitative characters. These two classes have also been called[10] oligogenes and polygenes respectively from the oligogenic and polygenic nature of the variation which they determine. With some important exceptions, which we shall discuss in a moment, the variant types to which switch, major or oligogenes, call them what we will, give rise, are not to be found in wild populations except as rare, and presumably recent, mutations; for unless some important end can be achieved only by diversity of allelomorphs of such genes, one allelomorph will have an unconditional selective advantage over the rest and will, apart from the slight effect of mutation pressure already noted, oust its competitors. Thus although we can only rarely detect the operation of such a gene by the genetical method of observing the different expressions of at least two allelomorphs, we must assume their action in wild organisms.

As but one allelomorph of any such gene is common in the wild, only those buffer genes which control the expression of this allelomorph will be subject to the action of natural selection. The systems buffering the action of the rare, or mutant, allelomorphs will not be so well adapted through selective action to the better fulfilment of their task. Hence when a mutation occurs in the laboratory, or a rare mutant type is found in and introduced from wild material, we should expect its phenotype to be more variable than the wild type, the buffering system of which is constantly adjusted by natural selection. This expectation is in full accord with the observed properties of mutant types, many of which have highly variable phenotypes. It should be noted that this argument presupposes that the various allelomorphs of a gene guide development into channels the directions of which are determined by unlike buffer genes. This has, in fact, now been verified by Haskell[11] in the case of the gene scute in *Drosophila melanogaster*.

The organization of the system of genes buffering the development of wild type individuals is of paramount importance to the organism. It must primarily determine the production of a relatively uniform type under conditions which may be subject to considerable fluctuations, as indeed is implied by ts description as a buffering system. Certain complications may be observed, as, for example, adaptation to show ecological plasticity, but these only serve to emphasize our main point, since they imply buffering in such a way as to produce two or more relatively uniform types according to the action of an environmental switch. But to be successful the system must have some elasticity, even though it is only potential, for the inability to respond to trend changes in the environment would mean that sooner or later the species would die out, no matter how well ts buffering system were adapted to coping with non-persistent environmental fluctuations.

The way in which uniformity is combined with potential elasticity has been revealed by Mather's[10,12] analysis of polygenic variability. The buffering ystem is built up of polygenes having effects which are similar to one another and individually small as ompared with environmentally determined fluctuaions. Natural selection builds up linked combinaions of these genes, in which the constituent members of the combinations balance each other in action. Inter-combinational uniformity of immediate action is combined with the ability to produce new combinations of different action by means of recombinaion between the various existing combinations. Thus the buffering action depends on polygenic balance, which can and does change as a result of ecombination, so permitting the emergence of new ombinations which are capable of re-aligning the developmental path to give fresh adaptation to hanged circumstances. The polygenic variability is hidden, or potential, in the genotype and is not free n the phenotype. In other words, we can see how, as Waddington puts it, the system has absorbed its own variability. Inasmuch as the maintenance of adequate polygenic balance depends on the regular action of natural selection[10], it is easy to see that the polygenic ystem buffering the expression of mutant switch genes will be inefficient, for it will not have been elected for inter- and intra-combinational balance.

This concept of polygenic balance, and the storage of variability in its potential form, enables us to approach a number of evolutionary questions. There is, for example, the problem of polymorphism, whether of the kind known in grouse locusts or mimetic butterflies, or the more familiar type, sex, heterostyly, etc., on which the breeding structure of a population depends. These are the exceptional cases mentioned earlier, in which the success of the species depends on diversity of a switch gene. It is of no use having females, for example, if no males are available.

The direct determination of sex depends on the action of the sex chromosome inequality, which is the switch gene in this case. But how is the organism adapted to produce functional females and functional males with but rare exceptional individuals, and how was this sharp difference in type of individual first produced ? Though we have stated the question in terms of sexual dimorphism, this is only a particular example of polymorphism, and the answer to this question will apply to polymorphic species in general.

Clearly this answer must be sought in the ability of the polygenic system to distinguish and delimit adequately the paths into which development can be turned by the operation of the switch gene. The latter may itself be composite and so capable of some modification[13], but, in the main, close adaptation must be polygenically determined. Only a polygenic system is capable of giving all grades of expression between wide limits. The balance achieved by the polygenic combinations will determine the end products, and if this balance is adequate the end products of the developmental paths will be functional male or functional female according to the line into which development was guided by the switch gene. Each type can, and will, be adjusted by the action of selection on the buffering system of polygenes ; and in so far as the types are capable of such adjustment, dimorphism will arise and develop continuously, under the action of selection, from the store of potential variability which lay hidden in the polygenic combinations of the undifferentiated ancestral form. The action of the switch gene, giving so obvious and sharp a discontinuity, is made possible by the continuous adjustment of polygenic balance.

Two predictions follow from this argument. In the first place, it should be possible to change the polygenic balance of a polymorphic system by operating on it with unbalanced combinations from a related system which is not adapted to show polymorphism. The polymorphism need not be lost in such a case : the switch gene will merely determine a less efficient polymorphism after the operation. This has been shown to happen to the incompatibility system in Petunia[14]. In *Petunia violacea* gametic incompatibility, which is a type of polymorphism affecting the breeding system, is determined by a series of *S* allelomorphs of the kind well known in Nicotiana species. The related *P. axillaris* shows no incompatibility. It was possible to isolate, from the F_2 of a cross between these species, plants identical in constitution with the *P. violacea* parent in regard to switch gene (that is, the *S* gene), but which were less strongly self-incompatible than was that parent. Furthermore, the two plants, *P. violacea* and the second generation species hybrid, were reasonably freely inter-compatible, though two plants of like *S* constitution within *P. violacea* would have been quite inter-incompatible. The polygenes from *P. axillaris*, not balanced to give incompatibility, have recombined with the balanced combinations of

P. violacea to give new combinations determining a new incompatibility system, which, however, depends on the same switch gene. As we should expect, this new system is not so precise in action as the old one, for these new combinations have not been fully balanced by the operation of natural selection.

Turning to the second prediction, we can see on the polygenic view that two related species, or populations, may show the same end result, yet reach it by balancing different polygenes of similar effect. Indeed, if the groups are isolated, this will be inevitable, because a polygenic system is in a constant state of flux. Its balance is stable but the constituent polygenes producing this balance are changing by mutation, fixation and so on. Now in such a case the joint balance of any pair of combinations can only be maintained by the continual operation of natural selection, and if two combinations are never present in the same nucleus, that is, are isolated, they will have a poor joint or relational balance, though they may have the same internal balance, and though each may be capable of working harmoniously with other combinations from which it is not isolated. Isolation means divergence of polygenic organization (but not of necessity of intra-group polygenic balance as expressed in the phenotype), because it prevents inter-group balance being maintained by natural selection.

It is to such inevitable cryptic divergence that we must attribute hybrid sterility in species crosses, though, of course, bars to crossing must have a selective origin. In particular, however, we should expect that two related species showing the same polymorphism, operated by the same switch gene, would depend on different sets of balanced polygenes to give this common result. On inter-crossing, therefore, the character in question should lose its sharp definition in later generations after the two sets of polygenes had recombined and so lost balance. This is found to be the case with incompatibility in Nicotiana. *N. Forgetiana* and *N. alata* show pseudo-compatibility only in exceptional circumstances, that is, the actions of the various allelomorphs of the switch gene are always distinctive; but in *N. Sanderæ*, a horticultural type derived by hybridization of the two foregoing species, pseudo-compatibility is rife, though the operative switch locus, *S*, is the same as that of both parental species[15]. Pseudo-compatibility marks the breakdown of the distinction between the types produced by the *S* allelomorphs. We can see that it is not the switch mechanism, but the buffering system of polygenes, to which the breakdown must be attributed, exactly as expected.

Thus the character or reaction, the expression of which is apparently dependent on the switch gene, is in fact conditioned by the buffering polygenes. If the latter are not adequately balanced the operation of the switch gene is partially or even wholly vitiated. The buffering system can also change in such a way that it endows the switch gene with an apparently new set of properties. The path or paths into which the latter directs development are so remoulded and redirected that the outcome is quite a new type.

Such changes can be recognized as having taken place in the evolution of flower colour differences in the genus Petunia[14]. *P. violacea* has magenta coloured, and *P. axillaris* white, flowers. The latter is homozygous for the allelomorph *w*, giving lack of anthocyanin in this species, of a gene the other allelomorph of which, *W*, homozygous in *P. violacea*, results in the presence of anthocyanin. When, however, the species are inter-crossed the F_2 contains coloured plants of the constitution *ww*, and what is more, these plants may have a flower colour indistinguishable, at least by inspection, from that of other plants which prove to be *Ww* when tested. The effects of the gene *W,w* are conditioned by the genetical background of the species. The background of *P. axillaris* is so adjusted that *w* switches flower development into a track leading regularly to white pigmentation. The buffering system of *P. violacea*, which does not carry *w*, is naturally not so adjusted and, in an F_2, affects the path of development so that *ww* expresses itself in a new way, namely, by giving coloured flowers. Thus the discontinuity in effect of *W* and *w* is a reflection of the buffering system. The switch gene has been given its characteristic properties by the adjustment of the genetical background or buffering genes. Clearly the evolution of such a specific difference can proceed gradually by continuous steps, even though the eventual discontinuity between the species is controlled by a few major genes.

This leads us to the problem of the relation of switch genes, major genes, oligogenes or whatever we choose to call them, which have large effects, to polygenes, the effects of which are so small as to be individually unrecognizable. It does not seem reasonable to suppose that the nucleus contains two kinds of genes, having sharply distinct properties (though it must be pointed out that there exist two kinds of chromatin, eu- and hetero-chromatin, the latter of which appears in general to be devoid of major genes but to contain polygenes). We have, however, seen that the apparently large phenotypic effect of a major gene is, at least in part, a property of the polygenes which determine the ultimate result of the major gene's action. In fact we may surmise that the difference in phenotypic expression between the allelomorphs of some major genes could be reduced to nothing by the reverse of that process of polygenic adjustment which has endowed them with the property of conditioning sharp phenotypic discontinuity.

But it would be straining both evidence and reason to suppose that a major gene was originally, in al cases, merely one of a number of like polygenes, any one of which might by chance have had the switching role thrust upon it by adjustment in balance of the rest. Rather it would seem that the switch gene operates at an earlier ontogenetic stage, the later acting genes then having the power of reducing or magnifying the difference in outcome of the path into which this major gene directs development and inasmuch as the latter genes do operate later their own effects are small and, at least in part interchangeable. We may note, too, that in such a case the organism could, without undue loss in fitness, afford to carry a greater store of variability for the later acting polygenes than for major genes for their individual disruptive action will not only be smaller, but will also be conditioned by the othe polygenes present.

This leads us to the speculation that major, switch or oligogenes were at one time polygenes. Th distinction between the two classes is one of time o action, and hence of magnitude of average effect, th apparent discontinuity of type being due to th buffering or enhancing action which the polygene exert on the effects of the earlier acting major genes In other respects the two kinds of gene are alike, fo both mutate, segregate and show linkage. It then follows that a gene which is now a polygene acting at a late stage in the development of an organ may, either alone or as part of a complex of linked polygenes, assume the role of a switch gene if and when the developmental history of that organ is extended by its morphological and functional elaboration. A gene which has a minor effect on the corolla structure of a relatively unspecialized flower could have a drastic effect on the corolla of a flower elaborated and specialized in the way observed, for example, in an orchid.

This is, perhaps, an unduly simplified discussion of the problem, and the questions raised, for example, by neoteny require consideration at a length not now possible. But the principle that genes have evolved in function can scarcely be denied. Indeed the evolution of an organism is an expression of the functional evolution of its genes.

STUDIES OF WILD POPULATIONS

By DR. C. B. WILLIAMS

AT a joint meeting of the Royal Entomological Society and the Genetical Society held on December 3, there was a general discussion on methods of study of wild populations.

Prof. R. A. Fisher, president of the Genetical Society, opened the proceedings with an account of recent developments in the method of estimating the numbers of a wild population by liberating a known number of marked individuals and later recapturing a random sample. Thus if a hundred marked flies are liberated and, after a short interval to allow of their mixing with the wild population, a number of flies are captured at random and found to include 1 per cent of marked individuals, then it can be assumed that the original wild population was approximately ninety-nine times the number of marked flies or 9,900 individuals.

If a series of such observations are made at short intervals, say on successive days or every week, it is possible to extend the mathematical analysis to supply estimates, on one hand of the death and emigration rates, and on the other hand the birth or immigration rates. If several contiguous areas are sampled the effect of birth and death can be separated from the effects of movement.

Since the total number of individuals captured and the total released on different days may vary, it is of value to convert all to a 'recapture frequency' which is the number of marked recaptures to be expected if both the numbers released and the total number recaptured were a hundred.

The method has been used particularly with tsetse flies by Jackson in East Africa and on certain butterflies and moths in England particularly by Ford, and there are interesting differences between the former case, in which the insects are flying over long periods with relatively small changes of number, and the latter, in which the brood rises to a peak and falls away again within a few weeks.

The idea of random sampling, which is the central and typical statistical operation, aims at supplying estimates of the population numbers, and birth-rate and death-rate, together with a knowledge of the precision of these estimates which is seldom available by other methods.

Dr. C. B. Williams dealt with some methods of finding the changes in insect population used at Rothamsted Experimental Station in recent years. Direct sampling had been used by Dr. H. F. Barnes to trace the changes in numbers of wheat midges over a period of fourteen years, and the number of slugs caught in thirty minutes at night had been found to be a fairly accurate method for estimating changes in a slug population. Direct sample counts had been used by K. D. Baweja to demonstrate the return of the insect population to an area of soil previously rendered sterile by heat.

The method of sampling by means of a light trap provided an interesting mathematical problem, as the catch in the trap is directly affected by changes both in activity and in population numbers. By considering the difference between catches at short intervals (for example, successive days) the activity factor became dominant, while by comparing monthly average captures in successive years the population effect was emphasized. It was then found possible to correct average catches for the effect of environment on activity and to have left a more exact measure of the population change. Later it was found possible to forecast these changes from a knowledge of the weather conditions during the previous months.

Dr. Williams also dealt very briefly with a new method, recently developed by Prof. R. A. Fisher and himself, for studying the relative abundance of different species in a mixed wild population. By means of a logarithmic series it is possible, if one knows the number of individuals and the number of species in a random sample of a mixed population, to calculate three sets of information. First the relative frequency of rarer and commoner species, as for example the number of species represented in the sample by one, two, three or more individuals; secondly, the number of species which would have been obtained in samples containing fewer or more individuals from the same population; and thirdly, a numerical measure of the extent to which the population is divided up among species, which has provisionally been called the 'index of diversity'. As the error of this 'index' can also be calculated it is possible to say if two random samples are taken from populations of similar composition or not. The calculated results fit very closely indeed to the observed numbers.

Mr. George Salt pointed out that there are two principal aspects to the study of animal populations. One can ask the question "How many ?" and answer it by making a census ; or one can ask "How do there come to be so many, neither more nor fewer ?" The curve of population growth, stated by Malthus on theoretical grounds to be exponential, was found by Pearl, Gauss and others in a variety of experiments to begin as though exponential, but then to change over to a sigmoid form. Three groups of factors have been suggested as effecting the change: competition for food, conditioning of the medium, and density of population. Owing to its applicability to human populations, the last of these has monopolized the interest of most observers; the second has been the subject of much work by Park; the first, competition for food, has been comparatively neglected. Experiments with blowflies show that, as increasing numbers of maggots compete for a fixed amount of meat, the average weight of the surviving larvæ gradually falls, there is an increasing loss of life in the larval stage, and eventually the number of survivors falls off rapidly. These laboratory experiments have their parallel in wild populations, and Holdaway has shown that, from an initial population of 63,200 Lucilia larvæ competing for carrion in Nature, only thirty reached the adult stage. A similar illustration of the law of diminishing returns has been demonstrated in a parasitic insect. In the case of these animals, and probably of others, it is in the larval stage, the principal feeding period, that the size of the population is largely determined by the available food supply.

Owing to the absence of Dr. Julian Huxley, who was to have taken part in the discussion, a communication was read from Dr. Ll. Lloyd on the effect of environment and competition for food on the insect fauna of sewage beds.

The population studied was made up of relatively few species, including three Chironomids, two Psychodids and one Enchytraeid worm, and it was possible in this simple community to see the effects of both intra- and inter-specific competition for food.

The vigorous Chironomid, *Metriocnemus longitarsus*, and the worm *Lumbricillus lineatus* dominate the situation and live in the topmost zone in the beds where the eggs of most species are laid. Cool wet summers are favourable to these dominant competitors, while hot dry summers are adverse to them. A cool June is followed by an abundance of *M. longitarsus* and a consequent reduction of the other Chironomids, *M. hirticollis* and *Spaniotoma minima*. The latter, however, specially counters the Psychodids deeper in the beds, so that these have a more prolonged abundance after a cool June.

M. longitarsus and *Psychoda severina* have the capacity of active winter breeding and one would expect that mild winters would be favourable to them. But the worm intervenes, and in a mild winter pulverizes the surface growth and sooner or later destroys it. Thus conditions are made more unsuitable for the two insects and they tend to become scarcer rather than more abundant in mild winters.

A. N. Barker, in a parallel study of the Protozoa of the beds, found a close negative correlation between the abundance of these organisms in summer and that of the grazing larvæ as assessed by fly trapping.

Dr. U. Phillip said that we can obtain information about the finer structure of free-living populations by studying both genetical and cytological variability. Genetical variability may be investigated by inbreeding insects from the field. It will then be found that every individual is heterozygous for at least one factor, if not for many more. From the occurrence of such factors the structure of the free-living population may be deduced. For the study of structural hybridity the larvæ of the Chironomidæ are very favourable material on account of their large salivary gland chromosomes. By investigating the frequency of various sequences of factors in the chromosomes (inversions) which occur together, it was found that larvæ living together in such a small closed locality as a rainwater butt came from a random mating population of unknown size.

We have so far had only indications of the type of breeding groups that may be found, because our methods of collecting and evaluating our results statistically are not sufficiently refined.

Prof. J. B. S. Haldane discussed the importance of genetic polymorphism in a wild population. He classified polymorphism as (1) manifest, for example as seen in mimetic associations; (2) cytological, in which the animals appear similar but have differences in chromosomes; (3) cryptic, as where recessive characters are normally hidden, but may be discovered to be present by inbreeding.

In the first two cases the population tends to come to an equilibrium in the proportion of the different forms, but not in the latter.

He pointed out that recoveries of individual Drosophila had been made in wild populations at some distance from the laboratories, which showed genes in certain combinations which had first been made in the laboratories. This indicated their origin by escapes.

An analysis of polymorphism throws light on the breeding system of a population, since a small inbred group soon becomes homozygous or nearly so. The study thus enables us to estimate the rough order of magnitude of an interbreeding population.

Mr. E. B. Ford directed attention to the relation between the size of a population and its variability as seen by him in a locality where the butterfly *Melitœa aurinia* occurred over a long series of years. At first the butterfly was rare and rather uniform in appearance. Then followed a period of rapid increase in numbers accompanied by a great increase in variability. Finally the population settled down to more or less stability of numbers at a level much higher than originally, and simultaneously it became much less variable, but not in the same form that had been dominant at the beginning of the observations.

Dr. E. A. Cockayne discussed briefly the problem of melanism and its occurrence in industrial areas. He considered that the melanic forms which became dominant in certain 'industrial areas' occurred as rarities over the rest of the range of the species. He also had evidence that there were frequently very considerable differences in the proportion of melanic forms in some species of moths in localities relatively close to one another, quite independent of any possible effect of the proximity of manufacturing towns.

Dr. W. Ripper expressed the hope that the method of correcting a sample for activity so as to leave a more definite population-number effect, as described by Dr. Williams for his light trap studies, could be extended to other sampling problems, particularly those of immediate agricultural importance.

Mr. Classey remarked that the varying proportion of the sexes in different species caught in a light trap might reduce the value of this as an estimate of populations.

Dr. P. A. Buxton, president of the Royal Entomological Society, in summing up the discussion, emphasized the great scientific and economic importance of the study of populations and said that nearly every problem in economic entomology is a problem of numbers. He suggested that it would be most valuable if someone could produce a critical review of the various methods now in use for obtaining estimates of the number of individuals in wild populations.

LUMINESCENCE AND COLOUR

A FEW years ago luminescence was little more than a curiosity of slight academic importance; to-day it forms the basis of new and important ndustries. The Colour Group of the Physical Society devoted its tenth science meeting, held on December 11, to its consideration, when four papers were read and discussed.

In the opening paper, on "The Chemical and Physical Properties of Luminescent Materials", Dr. J. W. Strange reviewed the development of luminescence and referred to the alchemical, if not culinary, flavour which still pervades the preparation of phosphors. He declared, furthermore, that the lack of rigid chemical control and co-operation between chemist and physicist has accounted for a good deal of the lack of progress in understanding luminescent phenomena. The words alchemical and culinary might, with some justice, be applied to the early attempts at making luminescent powders, but can scarcely be applied to the preparation of modern highly efficient phosphors, where chemical control is rigid in the extreme. So-called pure chemicals as purchased are rarely good enough for manufacturing luminescent powders, and these are generally subjected to careful purification before use.

It is true that theory lags far behind the practice of luminescence, and there does not appear to be much common ground as yet where the theoretical chemist or physicist and the luminescent powder chemist can meet. Nevertheless, as pointed out in the discussion following the meeting, acknowledgment must be made for the contribution of X-ray analysis to the development and understanding of crystalline phosphors. The way in which X-ray spectroscopy has contributed to the elucidation of luminescent problems has recently been described by Rooksby (*Electrical Times*, 102, 260; 1942).

Dr. Strange described the preparation of crystalline phosphors by firing the precipitated compound or the component oxides with the appropriate activating metal and flux at temperatures between 850° and 1,200° C. Manganese is the most important activator, but copper, silver, bismuth and a few others are also used, there being an optimum concentration for each phosphor.

Phosphors such as calcium and magnesium tungstates and zinc sulphide, which do not require an activator in the accepted sense, appear, at first sight, to conflict with the theory of active centres, which is largely based on the discovery that traces of certain heavy metals in a suitable crystalline matrix produce luminescence. The modern tendency, however, is to regard these apparent exceptions as conforming to the general rule. Thus there is evidence that in pure luminescent zinc sulphide there is a stoichiometric excess of zinc in the lattice which behaves as the activator. The main function of the flux, which is generally a halide, is to speed up the reaction or to bring it about at a lower temperature. Except possibly in certain sulphide phosphors, which require the presence of a halide for maximum efficiency, the flux does not appear to enter into the composition of the luminescent material.

Dr. Strange referred to some of the uses of luminescence in analytical work, atomic physics, electric discharge tubes and cathode ray tubes. In cathode ray tubes the relation between light output and tube current is of particular interest in connexion with theories of the mechanism of luminescence. It is a remarkable fact that the phosphor still continues to show an increase in light output with increase in current even at a power loading as high as 12 watts per sq. cm. of screen.

He concluded his remarks with a brief review of the modern interpretation of luminescence based on the idea that the atoms of the activator form the active centres for absorption and emission of radiation.

Mr. H. G. Jenkins read the second paper of the series, on "Commercially Useful Fluorescent Substances", which he dealt with under the headings: inorganic phosphors, fluorescent glass and fluorescent organic substances. A number of demonstrations were given to illustrate the luminescent characteristics of the various types of substances discussed.

The relation between the luminescent characteristics of the sulphide phosphors and the composition of the matrix, the activating metal and the furnacing treatment were briefly discussed. The most interesting property of the sulphides from the present point of view is their ability to fluoresce strongly when they are excited by near ultra-violet or even visible radiation.

Referring to the very beautiful colour effects obtained with these materials under filtered long-wave ultra-violet radiation, Mr. Jenkins mentioned that luminescent sulphide paints were being used very effectively before the War in conjunction with black-glass lamps for fluorescent posters and displays of great beauty and artistic merit. The black-glass lamp comprises a quartz high-pressure mercury vapour discharge tube rated at 80 or 125 w. in an outer bulb of nickel glass. The transmission of the nickel glass at 3650 A. is about 70 per cent and only a negligible amount of visible radiation is emitted by the lamp, which is one of the most convenient and efficient sources of near ultra-violet radiation available.

With normal paints and pigments, additive mixtures give subtractive mixtures of light. Thus a yellow pigment is yellow because it absorbs blue, and, as everyone knows, a mixture of blue and yellow paints gives green. In mixing fluorescent pigments, however, the artist has to deal with an additive mixture of *lights*, and he finds that blue and yellow no longer give green, but white. It is, of course, necessary for the artist to mix his luminescent pigments and to use them under ultra-violet radiation, with visible light excluded so far as possible. With comparatively little practice the new technique is easily acquired.

Some curious effects are observed with luminescent colours under conditions of scotopic vision; thus yellow luminescent inscriptions are more easily read than are blue, even when the brightness of the yellow is somewhat lower. This is probably due to the use of parafoveal vision for the shorter wave-lengths and consequent inability to focus. The high sensitivity of the periphery of the retina to blue and bluish-green colours makes it possible to see, although not to focus, these luminescent colours at brightness levels too low for normal vision to function. It can in certain circumstances produce a feeling of discomfort in the dark-adapted eye analogous to glare at normal illuminations.

Mr. Jenkins next described phosphors excited by ultra-violet radiation of wave-lengths shorter than 3000A., of which zinc silicate, zinc beryllium silicate and magnesium tungstate are perhaps the best known, and pointed out that these are commercially much more important than the sulphide types because of the efficiency with which they are excited by the low-pressure mercury vapour discharge. More than 50 per cent of the total input energy in the low-pressure mercury discharge is emitted as resonance radiation of wave-length 2537 A. and below. It is possible to convert a considerable fraction of this energy into visible light by means of fluorescence, resulting not only in sources of high luminous efficiency, but also, what is scarcely less important, in sources in which the spectral luminosity can be controlled.

As might be expected, luminescence in glass is even more complex and difficult to understand than that in crystalline materials. The luminescence centre may be an ionized molecule such as $UO_2{}^{++}$, or a covalent molecule such as cadmium sulphide, or neutral atoms such as silver, lead and tin; or the luminescence may be due to a crystalline material such as zinc silicate precipitated in the glassy surround. In the latter case the glass is opalescent due to the presence of undissolved crystalline material. Mr. Jenkins referred to the various types and showed a number of examples. Apart from its use for discharge tubes, the fluorescence of glass activated by rare earth atoms has been used to study the structure of glass and to supplement the information given by X-ray analysis.

Fluorescence has been used by glass manufacturers as a convenient method of identifying their product. Small amounts of cerium give a blue fluorescence and do not affect the colour or physical properties of the glass. Cerium has also been used as an indicator to study the movements of molten glass during manufacture.

Luminescent enamelled surfaces are usually prepared by binding certain sulphide phosphors in a boro-silicate type of enamel frit. By mixing suitable phosphors with certain synthetic moulding resins, luminescent plastics for use as switch covers, name-plates, etc., are prepared.

Referring to organic fluorescent materials, Mr. Jenkins mentioned that commercial anthracene is a characteristic example. This substance fluoresces green in the solid state and blue in solution in benzene, and the green bands reappear if the benzene solution is frozen in liquid air. Very pure anthracene fluoresces blue in both the solid and solution states. It thus appears probable that the green fluorescence is caused by an impurity, stated to be naphthacene, in the crystalline anthracene matrix, and that the blue fluorescence is a property of the anthracene molecule itself.

Many organic compounds are fluorescent only in liquid or solid solution states, or when adsorbed at high dispersion on fibres or on inorganic adsorbents. The fluorescent dyestuffs such as fluorescein, eosin, rhodamine and auramine are well-known examples. Unlike the fluorescent dyestuffs, organic materials such as anthracene, quinine, etc., which fluoresce in the solid state, possess little or no body colour. Some of these colourless substances have all the characteristics of fluorescent dyes and can be incorporated in fabrics like any ordinary dye to give a colourless dyeing which is highly fluorescent. Dyes of this type have found an interesting application for marking linen in laundries, the sorting being done under black-glass lamps.

For spectacular lighting and display effects, fluorescent dyes are often used in conjunction with resins as lacquers and applied by brushing or spraying. When the lacquer is dry, the dye molecules are dispersed in a thin film of resin which serves to isolate them energetically.

Two interesting engineering applications of organic fluorescent substances were mentioned. The first is in connexion with the surfacing of tools, gauges, etc., where the prussian blue used in the normal method is replaced by anthracene. The high spots appear as brightly fluorescing regions. The second application is to the detection of fine cracks in metals—particularly non-ferrous metals where the colloidal iron and powerful magnetic field method cannot be used. The metal part is treated with a strongly fluorescent substance, and after removal of this from the surface the cracks show up as fine bright lines under the black-glass lamp.

A paper on "Fluorescent Lamps: Their Photometric and Colour Rendering Properties and Measurement" was read by Mr. G. T. Winch. High-voltage fluorescent tubes, high-pressure mercury vapou fluorescent lamps and the newest types, the mains voltage fluorescent tubular lamps, were briefly reviewed. Mr. Winch described the accepted metho of visual photometry when colour differences are involved: the field of view is kept down to about 2° usually with a suitable filter in front of the sub-standard tungsten lamp to minimize the colou difference. The transmission factor for the filter is determined from its spectral transmission and the luminosity distribution of the sub-standard lamp Even when a colour match is achieved, it may b necessary to use a group of observers, owing to th large differences in luminosity distribution whic generally exist.

Discussing physical photometric methods, Mr Winch described his ingenious 'physical eye' photo meter, where the light from the source after dispersa in a spectroscope passes through an aperture o special contour before falling on the photo-electri cell. By adjusting the contour of the mask, th apparatus is made to have 'average eye' spectra response without any knowledge of the spectra sensitivity of the photocell.

The difference between the colour of a source an its colour rendering was strikingly demonstrated b showing the wide difference in colour rendering o fabrics which could result when placed under light of the same colour but of different spectral luminosit distribution. To assess the colour rendering propertie of a source, it is necessary to know something abou its luminosity distribution. It has been shown tha for most purposes it is sufficient to measure th relative luminosity in about eight suitably chose adjacent spectral bands. Much had already bee accomplished in this connexion, but although th method showed considerable promise, the War ha interrupted development work, and a good dea remains to be done before it can be applied t commercial fluorescent lamps.

Referring to the variability of natural daylig Mr. Winch pointed out that the colour temperature the light from the sun varies over the enormous rang of 2,000°–25,000° K. according to conditions. It for this reason that industrial establishments co cerned with colour rendering prefer, for their colou matching work, to use an artificial daylight sour corresponding to one of the phases of dayligh usually that of a black-body radiator at a temperatu of about 7,000° K. The luminous efficiency of thes artificial daylight sources is too low to make mo than localized lighting with them possible, and it was not until the introduction of high-voltage fluorescent tubes that general lighting at high illuminations with a light of daylight quality became an economic possibility. The more convenient mains voltage fluorescent tube which was introduced later has made this form of lighting much more generally available.

Mr. Winch described how, by a process of repeated interchanges of lamps and measurements between the leading lamp manufacturers, and elaborate colour-rendering tests with many observers, the luminosity distribution of the present 5 ft., 80 w. fluorescent lamp was evolved. The colour of the tube is fairly close to that of illuminant *C* specified by the C.I.E. (6,500° K.), and the colour rendering is adequate for nearly all purposes except those concerned with the most critical discrimination of colour. The daylight colour of these lamps has proved of considerable psychological importance in war-time factories and other situations where natural daylight is largely or completely excluded and where work is carried on for twenty-four hours of the day.

Mr. F. W. Coppin read an interesting paper on "The Use of Fluorescent Pigments in Colour Printing". Owing to the impossibility of ensuring that the printing inks used in photomechanical colour reproduction processes have the theoretically correct hue, compensating corrections have to be made at some stage in the process. For relief printing these correctives take the form of local adjustments to the dot size in the plates, or 'fine etching' as it is called, and for photolithography, hand re-touching of the screen. These operations are highly skilled and somewhat uncertain, and many attempts have been made to introduce the corrections by mechanical methods.

In the fluorescence process blue and green fluorescing materials are included in certain of the paints, and the colour separation negatives are made by mixing with the normal copying light some additional near ultra-violet radiation. The special paints comprise a set of eighteen water colours which are used by the artist under normal lighting conditions. Slight modifications in the normal technique are necessary to produce different hues by mixing colours, in order to avoid upsetting the fluorescence balance.

Arc illumination is used for making the colour separation negatives. For the yellow and magenta printing negatives, the arcs are shielded by special hoods fitted with filters which allow only ultra-violet, blue violet and green light to reach the copy. The correct ratio of ultra-violet to visible light is obtained by adjustable slits and compensating filters, using control patches on the copy-board. The blue-green printing negative is made using a panchromatic plate with the direct light of the arc on the copy and a Wratten No. 29 filter over the lens. For the black printing negative an infra-red sensitive plate is used and an infra-red filter over the lens.

Mr. Copping showed examples of colour charts prepared with the special paints and reproduced by the method described. For completely faithful reproduction, the hues of the four colour-printing inks should correspond to those for which the fluorescent paints have been balanced, but almost any good set of four colour inks will yield results which are sufficiently accurate for commercial purposes.

OBITUARIES

Prof. Franz Boas

PROF. FRANZ BOAS, who died on December 21 last, was born at Minden, Westphalia, in 1858, and did most of his scientific work in North America, becoming instructor in anthropology at Clark University in 1882 after university studies at Heidelberg, Bonn and Kiel. He worked in physical anthropology, linguistics, evolution of material cultures and social characteristics and ceremonial, besides writing suggestive essays on questions of wide interest and making a notable attack upon the racist theories of Nazidom. Though he thus clearly belonged to what in Britain is sometimes called the Huxley-Haddon tradition of general practice in anthropology, he yet showed, as did Huxley and Haddon, a capacity for detailed observation as well as wide generalization. Among the outstanding features of his scientific work were his studies of the Eskimo in Baffin Land (1883–4) and his plan for and conduct of the Jessup North Pacific Expedition (1897 onwards) to study the relationships of peoples of North America and Northern Asia. As professor of anthropology in Columbia University (1899 onwards), as well as for a time curator of ethnology at the American Museum of Natural History (1901–5), Boas found opportunities to co-ordinate the researches of different workers, and he became a central figure in the field of North American, and especially Eskimo, ethnology.

Boas's observations were much valued even if at times his theories were set aside; in such a field, theory is inevitably in a high degree provisional. He emphasized cultural similarities—the kayak, umiak, harpoon, household utensils, rituals and hero-tales, pictographic art and realistic carvings—between the Eskimo on one hand and the Chukchee and Koryak of north-east Asia on the other. But he rejected the view that the Eskimo peoples and their cultures had originated in Asia and spread to America. The findings of his Jessup expedition led him to think of the Eskimo of Alaska as comparatively new arrivals there from farther east in America. Indeed, he thought that several Palæ-Asiatic peoples of Siberia should be considered to have been immigrants from America. Needless to say, he shared the general view that the original peopling of America was due to movements from Asia; all he added to this was the idea of a backwash. Subsequent work has revealed evidence of older cultures in Alaska; and it is increasingly realized that diffusions of culture and movements of peoples in arctic America and the region around the Bering Sea have been complex, and probably by no means all in one direction; but ancient drifts from Asia to America are universally thought to have been fundamentally important. An Asiatic cradle for Eskimo culture is nevertheless not generally accepted, and Stefansson, for example, has the view that from the forests north of Lake Superior the ancestors of the Eskimo drifted northwards to the Barren lands and thence went on both eastwards to Greenland and westwards to Alaska. It seems established that the arctic Eskimo culture, which has an obvious unity throughout, came into the Arctic two thousand or more years ago, and was once more prosperous than it has been in recent centuries.

Boas believed that the peoples of the extreme south and south-east of South America and those of the north-west of North America must be considered fringing groups imperfectly imbued with the culture which had developed, in the main, on the American continent, though the roots might be Asiatic; he thus emphasized here again the importance, in his view, of cultural evolution in America. He believed that there were cases of similarities between peoples, due not to borrowing but to psychological factors working parallel to one another. He would, however, have nothing to do with necessarian theories. Totemism, for example, seemed to him to be a term covering a wide range of associated ideas and customs; but neither are the widespread similarities proof of a unitary origin, nor is totemism a necessary expression of thought of a particular stage in human evolution. After suggesting that the Northern Kwakiutl of the Northern Pacific were in a stage of transition from mother-kin to father-kin, he later went over to the opinion that from a father-kin system they were influenced towards a mother-kin scheme and division into totemic clans by borrowing from more northerly neighbours. Sir James Frazer held that the facts agree better with Boas's earlier view.

Deeply aware of the interdependence of all aspects of human life and work, Boas felt that as a teacher he could not easily neglect any. We thus have his comments and contributions in several fields. He thought of primitive art as arising from technical execution and also from the stylized expression of emotions and thought. Stylization seemed to him to give a measure in this field of work, provided it is understood in its broader sense of controlled form. He disagreed with the theory that geometric ornament develops through degeneration of perspective, or symbolic designs because of slurring and inaccuracy; and he emphasized the borrowings of forms and the changes in their interpretation as they pass from one people to another, or from one generation to another. Among one and the same people there may be two or more distinct styles, especially if these are associated with different industries carried on by distinct sections of the group. The desire for artistic expression, in his view, is universal.

In the field of physical anthropology Boas concerned himself to show the rapid mutability of head form, and he published elaborate statistics concerning descendants, of even the first generation, of immigrants from Europe to the United States of America. Some anthropometric workers accepted his conclusions, but some found difficulties in his analysis of the measurements he gathered; and it may be said that mutability of a rapid type is by no means a general feature, if it ever occurs, which is doubtful.

Boas's broad knowledge of material culture, linguistics, social organization, religious ideas and physical characteristics of human groups gave strength and cogency to his fiercely valuable attack on Nazi racism, and on all attempts to trim and distort scientific truth to suit dogmatic schemes in politics or in any other field of expression. He is one of those who have enriched the knowledge and understanding of mankind in more ways than can be specified by giving a list of special discoveries or theories or publications.

H. J. FLEURE.

WE regret to announce the following deaths:

Dr. George Washington Carver, director of the Research and Experimental Station and consulting chemist at Tuskegee Institute, Alabama, the distinguished Negro botanist, aged eighty.

Prof. R. G. Collingwood, F.B.A., late Waynflete professor of metaphysical philosophy in the University of Oxford, on January 9, aged fifty-three.

Dr. C. Tate Regan, F.R.S., lately director of the British Museum (Natural History), on January 13, aged sixty-four.

Dr. Nikola Tesla, the well-known electrical engineer and pioneer of radio telegraphy, on January 7, aged eighty-five.

Prof. Arthur Willey, F.R.S., emeritus professor of zoology in McGill University, on December 26, aged seventy-six.

NEWS and VIEWS

An American Steam-Boat Pioneer

ON January 21 occurs the tercentenary of the birth of John Fitch, the American pioneer of the steam-boat, who while other inventors were struggling with costly and inconclusive experiments built several working steam-boats, formed the first steam-boat company in the world and for a period carried passengers on the Delaware according to a time-table. Fitch was born at East Windsor, Conn., and after working on his father's farm, pursued various callings, including those of a brassfounder and a silversmith. He suffered many misfortunes, made an unhappy marriage, and during the War of Independence was taken prisoner. In 1780 he became a surveyor in Kentucky and later on took to map-making. On a journey in 1785 he conceived the idea of propelling vehicles and boats by mechanical means. Quickly visualizing the value of his ideas, he made models and drawings, secured favourable opinions from public men and during the years 1786–90 made three or four boats which ran with varying success on the River Delaware. In 1791 a French patent was secured and two years later Fitch visited France to further the exploitation of his invention in Europe. The Terror, however, was then at its height and he soon returned home, having exhausted his means. From that time onwards he strove unsuccessfully against an unkind fate, and died at Bardstown, Kentucky, in 1798, at the age of fifty-three. His merits have not gone unnoticed in the United States, and in 1926 Congress erected a memorial to him where he died.

Pamphlets in War-time

As in the War of 1914–18, so in this one, pamphlets are much in evidence. There is a saying of John Selden, who flourished in the seventeenth century, that "more solid things do not show the complexion of the times so well as ballads and libels". By "libels", however, Selden meant what we mean by pamphlets, for, as Archbishop Trench remarked, the extent of meaning which a word covers is often gradually narrowed. Any little book (*libellus*) was a "libel" once; now, only such as is scurrilous or injurious. The truth of Selden's saying is seen in the fact that pamphlets were plentifully produced until far into the nineteenth century, when popular magazines tended to replace them. Now they become plentiful again at times of great public excitement. The Oxford pamphlets of 1914–18 are still fresh in the memories of people who have reached or passed middle age. Pamphlets are with us again. They cover many subjects—scientific, geographical, historical, biographical, and all that relates to the Fighting Forces. For the most part they are authoritatively written, and "show the complexion of the times" very effectively.

Recent additions to the Oxford pamphlets (Oxford University Press, 3*d.* net) include Lieut.-Col. Casson's "Greece", written by one who is both a scholar and a soldier, and describing the character and traditions of the Greek people. Sir John Pratt, writing from an intimate knowledge of the Far East, describes in "Great Britain and China" the chief episodes in our relations with China since 1715, when the East-India Company set up its factory in Canton; and Admiral Sir Herbert Richmond, distinguished alike as naval officer and writer, in his "War at Sea To-day" makes clear to the layman the new difficulties of naval warfare, and the means adopted to meet them.

The latest addition to Federal Tracts, published by Macmillan and Co., Ltd. (6*d.* net), for Federal Union Research Institute, is Prof. George Catlin's valuable pamphlet on "Anglo-American Union as a Nucleus of World Federation"—a title which explains itself. The author's distinguished record as a student of politics, and as an exponent of this particular subject, marks him out as a high authority. World federation is for him the ultimate aim, but Anglo-American Union is the first step. Cultural autonomy is the due of all nations, even the smallest, but national sovereignty is not. Lord Balfour's reference to "an English-speaking method of looking at the great affairs of mankind" is recalled and enforced—that sense of a common culture which needs to be made more articulate. Prof. Catlin regretfully points out that the whole issue has received far less attention and publicity in Britain than in the United States and the Dominions.

"The Body as a Guide to Politics", by Dr. W. B. Cannon, formerly professor of physiology at Harvard, afterwards of the British Military Service, and later of the U.S.A. Medical Corps, is more directly scientific in tone. His general thesis, which may sound fanciful at first hearing, is that the external and internal relations and activities of the body are so marvellously organized by Nature that they may throw light on the present defects of organization by man. When danger threatens the body, stabilizing agencies act on the instant to guarantee security, but when danger threatens a nation disruptive factors have full sway. The pamphlet is an elaboration of the epilogue to Dr. Cannon's popular work "The Wisdom of the Body", published in 1932. It is included in the series "The Thinker's Forum", published by the Rationalist Press Association. In the same series appears Muriel Jaeger's "Wars of Ideas", expounding the claim that Nazi-ism is a new religion, with Hitler as its Messiah.

Geographical Names

THE vexed problem of geographical place names is raised again in an article in the *Geographical Journal* for October in which the Permanent Committee on Geographical Names of the Royal Geographical Society, Kensington Gore, S.W.7, enumerates certain principles which are offered for criticism. The whole memorandum is too long for extensive quotation but some of the main principles may be noted. Generally speaking, names should be those used by the responsible government or official survey of the country concerned, in the case of countries that use a Roman alphabet. In names of features or places in lands not using a Roman alphabet, transliteration, with certain qualifications, is recommended. But exceptions to these general rules are allowed. In popular, text and small-scale maps, English names of conventional usage are allowed; in learned works and large-scale maps conventional English names are allowed for marine features outside territorial limits and features of international interest, with the recommendation that the foreign official name, if it differs markedly from the English, should be given in brackets. Other exceptions are in favour of English or international postal names of important places that differ markedly from official names, and, in historical context, the use, either of the name or narrow transliteration of the name that prevailed at the time under consideration, or the name conventionally known to English scholars. It is emphasized that these principles do not necessarily represent the considered views of the committee but are put forward as a basis for discussion.

Russian Scientific and Technical Periodicals in Great Britain

ON the recommendation of the Anglo-Soviet Scientific Collaboration Committee, the British Council requested the Association of Special Libraries and Information Bureaux to undertake a survey of the war holdings of Russian scientific and technical periodicals available in Great Britain. The survey, covering the years 1939–42 inclusive, has just been completed, and summaries of the results may be obtained from A.S.L.I.B., 31 Museum Street, London, W.C.1 ("Wartime Guides to British Sources of Specialised Information, No. 4", 1*s.* 6*d.* to members of A.S.L.I.B., and 2*s.* 6*d.* to non-members, postage inclusive). More than two hundred specialized libraries participated in the survey, which covers three hundred and thirty-four periodicals. From the summarized results it is possible to tell at a glance whether complete series of each of the periodicals for the last four years may be consulted in the Science Library or Patent Office, whether complete series have been located in other libraries, or whether the series located are incomplete. For further detailed information concerning the location of incomplete sets and odd numbers of periodicals, application should be made to A.S.L.I.B., where an index showing the particular issues received, their location, and the conditions of their accessibility is maintained. It is apparent from the survey that very few of the 1942 issues have so far been located, but attention is directed to the considerable time-lag in transit.

Potato Tips as Seed

THE importance of the potato, not only as human and animal food but also as a raw material for the manufacture of starch, alcohol and synthetic rubber, has greatly increased in the U.S.S.R. since the War. At the beginning of the War a big increase in the potato crop was ordered by the Government, but to achieve the goal set, a large addition to the amount of seed potatoes available was necessary. Lyssenko claims that the problem can be, and to some extent already has been, solved by utilizing as seed small pieces of tuber weighing about half an ounce and containing one of the upper eyes. The rest of the tuber—about 90 per cent of the whole—can be used as food. It is said that tips yield as well as whole tubers and that their produce is less subject to disease. In 1942, in the U.S.S.R., 250,000 acres were sown with potato tips, and it is anticipated that ten times this area will be thus sown in 1943. This would mean an additional 8 or 9 million tons of potatoes in 1943 without having appreciably reduced the quantity available for food and industry in 1942.

Methods of Clearing Derelict Land

THE clearing and reclamation of derelict land has become an urgent problem on many farms in Britain to-day. In view of the recent developments in the mechanization of British agriculture, the new edition of Bulletin No. 101, "Hedge and Tree-Stump Clearing", by T. Swarbrick, recently published by the Ministry of Agriculture (price 6*d*.), should prove of great help to farmers faced with probably unfamiliar operations. The methods recommended fall into four groups: hand methods, the use of power, chemical agents and explosives. The means selected depends upon a variety of circumstances. Much can be done with timber jacks and monkey winches, especially when isolated trees are the chief problem. If hedges also need removing and no tractor is available, the use of a monkey winch in conjunction with explosives is suggested, for horses can then pull out the small stuff. As regards power methods, the track-laying type of tractor is undoubtedly most suitable for land clearing, but it is essential that full use be made of the dead weight of the tractor, its drawbar pull and the leverage exerted by making a high hitch on the tree and a low hitch on the tractor. Other forms of power such as steam tackle, gyro-tillers and bull-dozers can also do most valuable work, if the size of the job justifies the use of expensive equipment. Explosives, particularly gelignite, offer a simple means of removing tree stumps and hedges; full details are given in the bulletin as to how they should be employed. Farmers requiring further information or help are recommended to get in touch with the machinery sections of the county war agricultural committees, who are in possession of the necessary tractors and employ full-time machinery officers to organize the equipment.

School Science Teaching

THE recent issue of the *School Science Review* (No. 92, Nov. 1942) contains an interesting article, "School Science Teaching after the War", by Mr. E. T. Harris. Mr. Harris points out that science teaching before the War was greatly affected by economic and social conditions which, in some cases, created a hostile attitude. But now, due to its contribution to the war effort, science is valued and appreciated. The changed social conditions likely to prevail after the War should give impetus to the modern movement to stress the applications of science, but the principles should not be omitted. ". . . Science is a social phenomenon, and is only to be understood in relation to the human society in which it has developed and is developing. Its principles and its applications are closely interrelated aspects of the same social phenomenon, and they must be studied in conjunction." In discussing how this principle may be applied in teaching, Mr. Harris cites the introduction of general science and the greater attention which biology is receiving nowadays (see NATURE, 149, 456; April 25, 1942). There are two aspects to the study of science, (1) its historical and logical development and its social uses, and (2) its application to the pupil's life—his home, body, food, etc. Later in the science course should come a broadening of these early ideas, so that science is regarded as a struggle of mankind to master Nature for knowledge, power, and freedom.

A New Universal Bevel Protractor

MESSRS. E. R. WATTS & SON, LTD., 123 Camberwell Road, London, S.E.5, have designed and introduced a new type of bevel gauge which should prove a most valuable tool in the engineering workshop for the convenient and accurate measurement of angles. The instrument consists essentially of two straight-edges hinged together by means of the protractor head and capable of being set at any desired angle. The principal feature of this bevel gauge is the circular scale, which is divided accurately on a glass annulus mounted inside the head. The graduations on this scale are read by means of a high-power magnifier attached to the head and giving a wide field of view. The scale is most conveniently observed by looking through the eyepiece when the instrument is held in front of a source of artificial light, and under these conditions angles can be measured to within one twelfth of a degree. The straight-edges or blades are made of hardened steel and one of them is capable of sliding, an arrangement which greatly extends the range of the instrument, and two sizes of blade are provided—6 in. and 12 in. The sliding blade is secured by an eccentric operated by a lever extending from the centre. When fitted with the short sliding blade, the dimensions of the gauge, closed, are 6½ in. × 2⅜ in. × 1¾ in. and its accuracy in measurement is 5 minutes of angle. The blades are secured in angular position by means of a knurled ring concentric with and surrounding the protractor head so that, in all respects, this tool lends itself to rapid and convenient operation.

The Royal Observatory, Cape of Good Hope

THE 1941 report of H.M. Astronomer at the Cape, though showing only too clearly the impact of the War on South African astronomy, contains much of interest. The reversible transit circle has been fairly fully employed in making 7,234 transit observations, including fifty-seven of the moon, which were undertaken in view of the fact that lunar observations have perforce been dropped from the restricted programmes of many European observatories. With the Victoria telescope the stellar parallax programme has been continued, 2,642 plates having been secured during the year. A new determination of the parallax of Proxima Centauri, the star closest to the sun, gives 0·763″ ± 0·007″, in good agreement with the previously accepted figure of 0·762″ ± 0·005″; this should be compared with the value 0·756″ ± 0·007″ for α Centauri. It is interesting to note that during recent years the number of plates used for a parallax determination has increased to thirty, taken over three years or more: this change is fully in accord with the experience gained in the cloudier weather (but better seeing) at Greenwich.

The photoheliograph record of the sun's disc has suffered somewhat from the shortage of fine-grain plates, but a record, either on lantern plates or faster emulsions, was obtained on 311 days. Observations of occultations by the moon indicate a correction of 0·77″ to its ephemeris longitude, which is of course based on Brown's Tables. This correction is expected to reach zero in 1943. Cometary observations included the photographing of Comet 1941c (de Kock), which reached the second magnitude, and of Comet Cunningham, which did not live up to expectations and only just reached naked-eye brightness. The weather at the Cape over the year was cloudier than usual, rainfall being 40 per cent above normal, as the result of considerable falls on a large number of days rather than excessive falls on a few days. Substantial observing losses through cloud were recorded in the programmes of the Victoria telescope and of the photoheliograph, but in spite of the weather the increased efforts of a war-depleted staff actually raised the number of observations made with the transit circle.

A New Telephone Set for Partially Deaf Persons

AN article by A. Herckmans (*Bell Lab. Rec.*, 21, No. 2; October 1942) describes a new amplifying set which recently has been developed for use with the regular telephone set to assist the hard of hearing, and which permits all the added equipment except a small 4½-volt battery to be incorporated in the base of the telephone. The gain of the amplifier is adjusted by turning one of the switchhook plungers, and the amplifier can be disconnected by a second switch controlled by this same plunger. The switchhook plunger at the right of the set gives gain control and it may be turned to any one of three positions to give low, medium or high gain. Vertical motion of the plunger removes the amplifier from the circuit entirely. The very small amplifier unit consists of a granular-carbon microphone the diaphragm of which is actuated by a bipolar receiver element using permanent magnets. A soft rubber mounting prevents it from picking up vibrations from the surface on which the set is resting. When the amplifier is in use its receiver element is connected in place of the regular handset receiver, while its transmitter element is connected to the handset receiver in series with a 4½-volt battery which may be placed in any convenient location and connected to the set by two wires. With this arrangement the handset receiver is operated by the amplified speech from the transmitter element of the amplifier.

To prevent 'singing', the amount of gain around the closed path from the receiver to the transmitter through the air path and then back to the receiver through the induction coil must be less than the total loss. A maximum of 25 db. gain is provided by the amplifier used and 'singing' will not occur in normal use. A person is not conscious of impairment of hearing for ordinary room conversations until his loss is about 25 db., and only about 5 per cent of the population would be conscious of the need for a hearing aid. This percentage would be smaller for telephone conversations because the average speech level received is approximately 10 db. higher than that of normal direct conversation. With the additional 25 db. provided by the new set, persons with as much as 60 db. loss will receive adequate volume. Since only 0·5 per cent have a loss greater than this, the new set provides the help needed for about 90 per cent of those conscious of hearing impairment and would undoubtedly give considerable assistance to many with losses in excess of this.

Application of Electricity in Mine Pumping

G. B. Alvey and N. Tetlow, in a paper on this subject read before the Institution of Electrical Engineers on December 10, give a good deal of useful information upon electrically driven mine-drainage pumps, which may be of the centrifugal or of the positive displacement reciprocating type. Since the characteristics of the driven pump have a considerable bearing on the choice of the most suitable driving motor, the first portion of the paper deals with operating and design characteristics of the two types of pump. The remainder shows how, by a study of these operating characteristics, the most suitable type of driving motor may be chosen.

Control of Venereal Diseases in Peru

LAWS concerning the medical care of patients suffering from venereal diseases in Peru have recently been promulgated by the President (*J. Amer. Med. Assoc.*, October 17). A national department dealing with these diseases has recently been established with its headquarters in Lima. Treatment during the contagious stage is obligatory. If the patients are minors or mentally deficient, the parents are made responsible for their treatment. Drugs for the treatment of venereal disease are now sold only on medical prescriptions, and the sale of specific medicine by unauthorized persons and treatment by correspondence are prohibited. Wet nurses must have a certificate of health, which is given free of charge in the dispensaries and hospitals. Five per cent of all the beds in public hospitals are to be reserved for venereal diseases.

Edinburgh Geological Society: Clough Memorial Medal and Fund

THE Clough Memorial Medal for the years 1941–1942 has been presented to Mr. James L. Begg, of Mount Vernon, Glasgow, for his outstanding contributions to Scottish palæontology. He has worked for many years on the Ordovician rocks of Southern Scotland and has discovered more than a hundred new species of trilobites, mollusca, brachiopods, and other organisms, many of which belong to new genera. The majority of the specimens have been obtained from the classical sections of the Girvan region. Mr. Begg, who is a past president of the Geological Society of Glasgow, has also served as its honorary treasurer for the past twenty-five years.

The Clough Memorial Fund was instituted in 1935 for the purpose of encouraging geological research in Scotland and the north of England. The north of England is defined as comprising the counties of Northumberland, Cumberland, Durham, Westmorland, and Yorkshire. Under the terms of the administration of the fund a sum of approximately £30 is available annually. Applications for grants are invited for the period April 1, 1943–March 31, 1944. These should be sent to the Secretary, Clough Research Fund Committee, Edinburgh Geological Society, Synod Hall, Castle Terrace, Edinburgh.

Greetings from Russian Physiologists

PROF. A. V. HILL, joint secretary of the Royal Society and foreign secretary of the Physiological Society, has received a cable of New Year greetings from the All-Union and Moscow Societies of Physiologists, Pharmacologists and Biochemists, expressing their confidence in complete victory during 1943 for the democratic countries. In his reply, Prof. Hill said he looked forward to joining with them in holding the Congress of Physiologists deferred from 1941 in Great Britain during 1944.

A World Language

Sir Richard Gregory, in his recent address to the Association of Special Libraries and Information Bureaux (ASLIB), reported in Nature of November 28, refers to the importance of developing a world language for international use after the War. He mentions the British Association Committee's investigations in 1919 which directed attention to the three alternatives:

(1) The use of a dead language, for example, Latin.

(2) The use of a national language, for example, English.

(3) The development of an artificial language such as Esperanto or Ido.

I venture to suggest that a fourth alternative should now be considered, namely, the use of a systematic sign language, as was proposed, nearly twenty years ago, by Prof. Daniel Jones, of University College, London.

I would exclude the instinctive pantomimic gesture language, as developed by all deaf mutes, for this language is *not* built up of separate signs equivalent to spoken words, and it is therefore almost as unfamiliar to all users of spoken language as spoken language is to the uneducated deaf. The natural pantomimic gesture language of deaf mutes represents in fact a different and altogether more primitive way of thinking from that used in normal speech.

The sign language for international use would be one (like the Red Indian sign language) in which every sign is the equivalent of a spoken word—so as to represent a unit of thought—but in which every sign is also pantomimically related to the meaning which it bears.

I have suggested elsewhere[1] that the spoken languages of primitive man were, in the main, derived from pre-existing sign languages of this type, the simple cause being that (as Darwin pointed out[2]) man's mouth and tongue tend to copy the movements of his hands.

From this it followed that *all* sign language was inevitably accompanied by gestures of articulation, while the equally natural urge of man to express emotional states by laryngeal sounds supplied the acoustic energy needed to convert gestures of articulation into audible speech sounds[3].

The advantages which may be claimed for a systematic sign language are:

(1) That every sign will appear natural to all nationalities alike.

(2) That—as experience has shown—the individual signs will be easily and quickly learnt and remembered.

(3) That the symbolism—being essentially pantomimic—will be more direct than that of any spoken or invented language.

(4) That the language will lend itself especially to use by children and the rising generation—as a form of play—and will give them at the same time a datum line from which to judge and compare the spoken languages.

(5) That the sign language will be at once simpler, more concise, and more unambiguous than any spoken language—owing to the much greater versatility and precision of the human hands as compared with the human organs of articulation (lips, tongue, etc.).

(6) That the sign language will be very easy to teach—on a world scale—by means of educational films and television, and that it will be free from all difficulties of pronunciation.

(7) That there is already available a vocabulary, of just under two thousand words, which any interested student of average intelligence might expect to acquire within a month. A longer period of practice would, of course, be necessary for gaining speed in signing and reading.

On the other hand, sign language has certain disadvantages, namely:

(1) It is at present unfamiliar—except to the born deaf.

(2) There is not, at present, any available script by which the hand gestures can be recorded and read—unless a cinema film of the person signing can be considered as a script of his signs.

Unfamiliarity of sign language is almost certainly not a serious objection—as witness the fact that all nationalities communicate by signs when the intending communicators cannot understand each other's spoken language.

The absence of a script, on the other hand, is a serious disadvantage, and the invention of an efficient script would be an essential factor in the development of sign language as an auxiliary international language.

Shortly before the present War broke out, that great master of script, Eric Gill, had begun to interest himself in the problem of devising a script for sign language. His premature death was a heavy blow not only to sculpture and the arts generally but also to sign language.

If any readers of Nature—or their friends—should be disposed to investigate the problem of recording the three-dimensional movements of sign language by means of a simple and artistic two-dimensional script, I would gladly give them any help in my power.

Miss Margaret Morris has devised a script for recording all the bodily movements in dancing[4]—the problem is much simpler in the case of sign language, where (in effect) only hand movements are concerned.

Control of Potato Blight (*Phytophthora infestans*) by Spraying with Suspensions of Metallic Copper

In 1807 Bénédict Prévost found that germination of the spores of the wheat bunt fungus (*Tilletia caries*) in water was inhibited by the presence of submerged pieces of clean metallic copper[1]. It has long been known that water contained in copper vessels becomes toxic to some species of algæ and bacteria. Since about 1885 many compounds of copper have been used in spraying plants for the control of fungus diseases, but in an extensive search of the literature[2], I have not found a single reference to the trial of finely divided metallic copper itself, for this purpose

Following the work of Horsfall, Martin, Marsh[3] and others, cuprous oxide has recently come into wide use as a general fungicide, but the mechanism of its action remains obscure. It is possible that in presence of some exudate 'E' from the fungus itself, one of the steps in the reaction may be:

$$2Cu_2O + E \rightarrow Cu_2 + 2CuE,$$

and it therefore becomes of much interest to examine the fungicidal effect, not only of the free cupric ion, but of the molecular copper that may be deposited.

The conduct of comparative trials of Bordeaux mixture, cuprous oxide, copper oxychloride and other copper compounds for the control of potato blight in Devon and Cornwall this year, gave me the opportunity of including plots sprayed with suspensions of finely divided metallic copper. Among the methods used in preparing these suspensions were: (*a*) reduction of copper sulphate with sodium hydrosulphite, (*b*) treatment of cuprous oxide with sulphuric acid, followed by repeated washing to remove the ionic copper, (*c*) precipitation of copper metal in dispersible form from copper sulphate solution with zinc dust, and (*d*) simple dispersion of fine electrolytic copper, or technical (B.D.H.) hydrogen-reduced copper metal. Methods (*a*) and (*b*) gave copper particles mostly of about 1 μ, and methods (*c*) and (*d*) mostly of 2–5 μ in diameter. Small-scale trials showed, as was to be expected[4], that suspensions of the smaller particles were the more effective, but for the main trials, on randomized plots, suspensions made by method (*d*) were chosen, to put metallic copper to the severer test, and to avoid the possibility of including traces of soluble copper compounds through incomplete washing out of the other materials.

Dispersal of the copper particles to obtain preparations in convenient practical form for application to the plants was secured by trituration of the reduced copper, in a dry or moist state, (*a*) with sulphite cellulose extract ('Sulphite lye'), or (*b*) with a mixture containing 97 parts of bentonite, 2 parts of aluminium sulphate, and 1 part of soda ash, by weight. Bentonite was used to ensure good adhesion to the foliage, as well as to stabilize the copper suspension. The small addition of aluminium sulphate and sodium carbonate in the above proportions was found to overcome the difficulty previously experienced when using bentonite with spray materials, due to its 'balling' into very slowly dispersible, sticky masses on addition to water. The method is an improvement on others I have used for this purpose[5], and its underlying principle is to prevent swelling of the bentonite when the preparation containing it is creamed with a *little* water, without causing flocculation of the fully diluted suspension. The same additions to the bentonite were made in preparing both the metallic-copper and the yellow cuprous-oxide suspensions referred to in the table below.

The chequer-board spraying trials were carried out on Arran Banner at Bude (1), and on Majestic at Dartington (2) and Kentisbeare (3). There were three replications of each treatment at each trial. All the spray fluids were made up to the same copper content, namely, 0·25 per cent copper by weight, and two applications were given, the first at the rate of 110 gallons per acre, the second at 140 gallons per acre, using a knapsack sprayer. Detailed assessments of the percentage of the foliage area affected by blight, on each individual plot, were made at frequent intervals. Full particulars of the trials will be published elsewhere, but, in short, at all three centres the blight attack, though late, was severe, and the metallic copper sprays, though not quite so effective as Bordeaux mixture, kept the plants green for three weeks after the unsprayed were dead, and throughout gave such good control of blight on the foliage as to indicate beyond doubt that metallic copper has very marked fungicidal activity, at any rate against *P. infestans*.

The effect on the yield of tubers was as follows:

	Mean total yield in tons per acre		
	Arran Banner (1)	Majestic (2)	Majestic (3)
Bordeaux mixture	14·4	14·3	16·1
Cuprous oxide plus bentonite	15·4	14·3	14·7
H-reduced copper plus bentonite	13·8	14·6	14·3
Control, unsprayed	10·6	11·1	11·6
Significant difference between treatment means (P=0·05)	1·4	1·7	1·8

The deposits on the leaves of the plants sprayed with finely divided copper appeared to retain the colour of the metal throughout the trials, but the possible occurrence of oxidation of the metal on exposure remains to be investigated. It also remains to be ascertained whether the fungicidal action of metallic copper, or of oxides resulting from the application of copper in metallic form, is specific to *P. infestans* or of wider application. If metallic copper sprays prove effective against the apple scab fungus (*Venturia inæqualis*), for example, they may be of great value on the copper-sensitive varieties, as there would appear to be less likelihood of scorch with metallic copper than with its more soluble or reactive compounds.

Loss of Thiamin from Cooked Potato

IN the course of assays of thiamin (vitamin B_1) in potato by the Phycomyces method[1], which involves cooking the potato samples in the process of sterilization, the method of sterilization was varied from time to time. One of these variations was of sufficient culinary interest to be briefly reported.

The normal method of conducting the Phycomyces test is to grow the fungus on small cylinders of potato in a liquid medium (pH 6·4); medium and potato are sterilized together by steaming for 45 minutes on three successive days. This process does not destroy the vitamin, for determinations by this method gave concordant results with those made at the same time on raw potato by the thiochrome method[2]. If, however, the medium is poured off from the potato after the three steamings, and replaced by fresh sterile medium, the loss in vitamin

LOSSES OF THIAMIN FROM MAJESTIC POTATOES.

Date	Thiamin in sample, sterilized normally (μ gm./100 gm.)	Thiamin (μ gm./100 gm.) remaining	
		After pouring off medium	After sterilizing at pH 9
Nov. 1941	103	34	26
Jan. 1942	179	11	21

is considerable. It is comparable with the loss incurred by sterilizing the potato at pH 9 instead of pH 6·4, as is shown in the table.

It would appear that the greater part of the vitamin is washed out into the medium in the process of steaming. These figures afford an additional argument in favour of always cooking potatoes in their skins.

Effect of Hexœstrol and of Alpha Methyl Stilbene on the Insulin Content of the Pancreas of the Rabbit

CONSIDERABLE evidence accumulated during the past two years shows that administration of natural and synthetic œstrogens increases the amount of insulin in the pancreas of the rat[1,2,3,4].

Further experiments on the action of the synthetic œstrogen hexœstrol, 4 : 4′ dihydroxy - α, β - diethyldihydrostilbene, on the insulin content of the pancreas of the rabbit have been carried out in this laboratory. Some experiments using α methyl stilbene, of which Dodds, Fitzgerald, and Lawson[5] have found that even very large doses are non-œstrogenic, have also been carried out. The results are summarized in the following table.

The two substances were dissolved in arachis oil and injected intramuscularly, over periods of 4–10 weeks.

TABLE 1.

Number of rabbits	Substance injected and average total dose	Body weight grams		Blood sugar mgm.%	Liver wt. grams	Testis wt. (2) grams	Adrenal wt. (2) grams	Insulin content in units gram of pancreas
		Init.	Final					
5 (1 female)	—	—	2,215	102	53·0	4·28	0·32	5·20
5 (1 female)	40 mgm. hexœstrol	2,386	2,306	98	44·2	1·27	0·31	8·85
3	320 mgm. of α methyl stilbene	2,190	2,323	84	66·0	4·35	0·47	24·49

From this table it is seen that the hexœstrol brings about atrophy of the testes and a moderate increase in the amount of pancreatic insulin. α methyl stilbene, on the other hand, increases the amount of pancreatic insulin to a marked degree, but has no effect on the testis weight, which result substantiates the finding of Dodds, Fitzgerald and Lawson that it is non-œstrogenic.

This report will be published shortly in the *Proceedings of the Linnean Society of New South Wales*.

I wish to take the opportunity of acknowledging my indebtedness to the Society for a scholarship grant, and to Prof. C. G. Lambie for his interest in this work.

A Census of Atmospheric Pollen

THE pollen content of the atmosphere is of interest in relation to general plant biology, the pollen analysis of peats and the study of allergic diseases such as hay fever and asthma. This subject was first investigated by Blackley[1] in Great Britain and has since been pursued on a wide scale in the United States[2]. So far as is known to us, however, it has received attention from only a very few workers on the Continent of Europe[3,4,5] and no such researches made in Great Britain (other than Blackley's) have been published.

We have recently completed a continuous investigation of the day-to-day changes during twelve months in the pollen rain at Llandough Hospital, Cardiff. Microslides previously coated with glycerine-gelatine containing fuchsin as described by Wodehouse[6] have been exposed, one every twenty-four hours, in a horizontal position under conditions which allowed reasonably free passage of air over them while affording protection from rain. Each slide was then mounted and all pollen grains under a $\frac{7}{8}$ in. cover-slip were identified so far as possible and counted.

The effective pollen season was found to extend from the middle of February to the end of October and to fall into three main phases, dominated by trees, grasses and herbaceous dicotyledons respectively. Of the trees, birch (Betula) gave by far the highest pollen count, 315 (63 per sq. cm.) on April 28–29, and yew (Taxus) gave the next highest, 142 (28 per sq. cm.) on March 26–27. Oak (Quercus) had a medium value, 92 (18 per sq. cm.) on May 16–17, as did elm (Ulmus), 83 (17 per sq. cm.) on March 27–28, and hazel (Corylus), 63 (13 per sq. cm.) on March 20–21, while alder (Alnus), 29 (6 per sq. cm.) on March 25–26, was relatively low and ash (Fraxinus), 12 (2 per sq. cm.) on April 11–12, was very low.

The grass pollen, from being negligible at the beginning of June, reached 386 (77 per sq. cm.) on June 11–12 and a maximum of 482 (96 per sq. cm.) on June 22–23. It was still 395 (79 per sq. cm.) on July 5–6, but toward the end of this month the number fell rapidly.

The phase of herbaceous dicotyledons, including chiefly the genera Urtica, Plantago and Artemisia and the family Umbelliferæ, gave low values only: Urtica 27 (5 per sq. cm.) on August 27–28 and 10 (2 per sq. cm.) on September 6–7, Umbelliferæ 10 (2 per sq. cm.) on August 27–28, Plantago 5 (1 per sq. cm.), and Artemisia 12 (2 per sq. cm.) both on August 20–21, while 10 grains (2 per sq. cm.) of the Compositæ—(Aster type)—were found on October 4–5. Pollen of some of these genera was found in larger quantities, however, during the grass season, namely, Urtica 58 (12 per sq. cm.) on June 19–20, Plantago 28 (6 per sq. cm.) on June 6–7 and Umbelliferæ 24 (5 per sq. cm.) on May 27–28.

Certain entomophilous pollens appeared in surprising numbers; for example, Cruciferæ 90 (18 per sq. cm.) and elder (Sambucus) 21 (4 per sq. cm.). In all, some sixty types of pollen have been recognized on the slides.

The detailed results of the year's work will be published elsewhere.

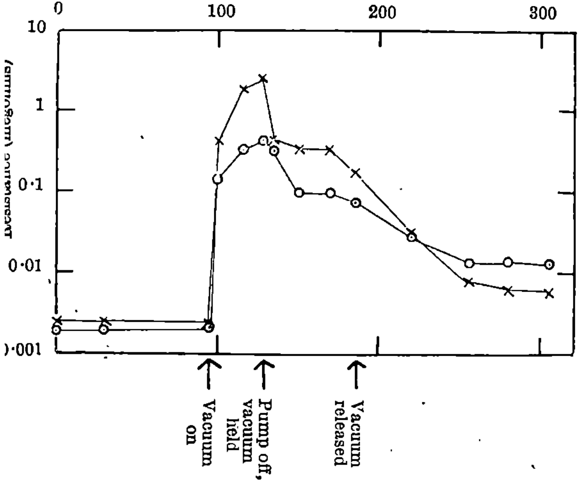
Electrical Resistance of Wood

THE electrical resistance of wood increases very rapidly with decrease in moisture content (grams of water present per 100 grams dry weight), so that, if two probes about 2 cm. apart are driven into the centre of a drying board, the resistance between the probes can be used as an indication of moisture content.

When beech wood is heated to just over 100° C. in a confined space at atmospheric pressure and the space suddenly evacuated, we have found that, for moisture contents between 30 and 40 per cent, the resistance between the probes increases by a factor of as much as 200 : 1. This is shown in the figure, where the resistance is plotted logarithmically. The increase might be interpreted as a rapid and large reduction in moisture content, but direct measurement shows, as one would expect, only a small reduction due to loss by evaporation.

That the apparent decrease in moisture content is not real is proved by readmitting air, or by maintaining the vacuum without further pumping. In either case, the resistance is found to fall gradually to something approaching its former value.



These observations suggest that the current path in moist wood is principally along the interior surfaces of the cells. If the current path were through the body of the cell walls, the sudden drying of the interior surfaces on evacuation could only cause an insignificant increase in the average resistance, whereas the observed resistance increases between one and two hundred times.

The effect appears to be confined to initial moisture contents below 30–40 per cent, that is, to the condition where the small local drying is not at the expense of the 'free' water present in the cell cavities, but has the chance of reducing the moisture in the surfaces themselves.

Measurement of the change in resistance of the wood as it is being heated up prior to evacuation shows that the temperature coefficient of resistance is negative, which indicates that the conduction is ionic as in a solution. The temperature coefficient is, however, too small to account, in terms of local cooling, for the large resistance change on evacuation.

Human Activities and Soil Characteristics

ADDITIONAL evidence to that given by K. L. Robinson in NATURE of July 4 of changes in soil profiles of the New Forest since its occupation by early man has latterly come to light from under tumuli in the New Forest. These have been investigated archæologically by Mrs. Stuart Piggott, to whom I am indebted for the opportunity of seeing some of the exposures and discussing her findings, the early publication of which is anticipated.

The tumuli date, I am informed, from the Bronze Age, probably 1500–1200 B.C., and I know of no evidence of any earlier human occupation of this district. The sections were of pedological interest for their indications of changes of soil profile during the succeeding 3 to 3½ millennia of human occupation. Certainly throughout written history, and almost as certainly throughout pre-history, the hand of man has lain but lightly upon this hunting preserve cum free-range pastoral district, and it can have been subjected to nothing like the several drastic alterations of ecology implicit in the farming history of more normal agricultural districts.

One sectioned tumulus had a massive core of neatly piled sods of thick black heath peat, 3–4 ft. in thickness, above the old soil line and the central interment. These sods apparently represented the A_0 horizon from a mature and fully developed podsol profile, and adherent to each was its thick and well-developed bleached horizon (A_1); the core comprised quite two thirds of the volume of a cast or central mound about 40 ft. in diameter, and was topped over with 2–2½ ft. of sandy gravel. This latter appeared identical with the plateau-gravel subsoil underlying this heath. I should estimate the mound to have contained 90–100 cubic yards of compacted soil, probably more when loose and newly piled. This considerable weight of material was transported, one assumes, by hand in baskets, and therefore collected from a local source, in the narrowest sense of the word.

The present vegetation of this plateau site is Calluna, well scattered with ill-grown *Erica tetralix*, pervaded with dwarf *Molinia cœrulia* and a scatter of *Agrostis setacea*, all short of stature. Its modern profile, while podsolic, is unorthodox and not comparable with the ancient clear-cut and well-developed podsol beneath the tumulus, or of the sods at its core. It presents anomalous features as to which, since my war-time circumstances denied facilities for the necessary analyses, I cannot be at all particular. The differences most apparent to the eye are first, that the surface peat, A_0, is but ½–¾ in. thick instead of 1–2½ in., and secondly, in place of a well-marked pale bleached layer it has for A_1 an inch or two of black humic sand next below, passing fairly sharply into a dull medium yellow pebbly sand. To-day, therefore, it would not be possible to duplicate the sod-core of the tumulus within any reasonable carrying distance. One deduces that the ancient podsol profile has been robbed of its A_0 and A_1 horizons, and maybe of its B horizon during the thirty or so centuries of human occupation. The periodic heather burnings to freshen the grazing, and the now vanishing local manner of paring thin surface peats for domestic fuel, are probably responsible.

I agree with Robinson's conclusion that we have here a range of formerly mature podsols, mainly truncated through man's activities in the human era, and now in various phases of immaturity, undergoing regrading of a podsolic character.

A similar tumulus from a southern New Forest parish presented a different question in that the present conditions of the surroundings are of a moist heath with impeded drainage and gleyed subsoils of variable character, even more in contrast to the clear-cut podsol profile suggested by the sod-core, and the old soil-line beneath the tumulus. The original bottom of its surrounding ditch proved on excavation to be considerably below the present water-table of the site. The subsidence which flooded the vales of the Solent and Spithead rivers and made Wight into an island is believed to have occurred in middle or later Bronze Age times, so it may be that earth movements or minor foldings related to that subsidence are responsible for this revolution in drainage conditions.

If a district by comparison so lightly pressed by the hand of man can present profile immaturity problems of this degree, how much more complex the undeciphered sequence of partial regradings confronting the pedologist in the soils of farming England with their history of transformations: from forest cover to open-field manor, from this to grass at the Black Death, thence to enclosed arable for the Napoleonic War, and so on. This profile immaturity due to centuries of relatively dense human occupation and changing land-utilization seldom receives adequate allowance in considering the late start and the difficult progress of pedological survey in Great Britain.

A Modified Calomel Cell for pH Measurements

THE present shortage of potassium makes it necessary that chemists should take every care that there is no undue waste of this material, and it seems to us that with the large number of workers using the saturated calomel electrode[1] for making *p*H measurements, there must be a considerable loss of potassium chloride resulting from the frequent flushing of the liquid junction. The use of normal and decinormal potassium chloride cells would do much to avoid this waste, but they are neither so quickly prepared nor is the conductance of the cells so good as that of the saturated type.

We have experimented with a saturated calomel cell in which the potassium chloride has been replaced by sodium chloride, and it was found that well-defined potentials are obtained. The potential of the sodium chloride type of cell referred to the normal hydrogen electrode is a little lower than the potassium chloride cell, but there is not likely to be any inconvenience arising from this difference.

Saturated sodium chloride cells were made up by us and tested independently against saturated calomel cells of the conventional type. The sodium chloride cell had a potential of 245·8 mv. at 20° C.

It is well appreciated that for precise work in physical chemistry the potassium chloride cell is better, but there must be many hundreds of workers making routine *p*H measurements of a lower standard of accuracy where slight errors due to the difference in ionic mobilities are unimportant; further, there is the saving of potassium chloride and also of expense.

Further work on the potential and the temperature coefficient of the cell is being undertaken to assess the value of this cell for more precise work.

Newton and the Apple

IN my recent address on Newton to the Royal Society, a version of which was published in NATURE of December 19, I stated that the story of the apple first appeared in the second edition of Voltaire's "Elémens de la Philosophie de Neuton", printed in 1741. The point which I had in mind was that the story is not given in the first edition of that book which appeared in 1738.

Mr. Arthur Hawkes, borough librarian of Wigan who organized the effective Newton exhibition recently held in that town, has written to me pointing out that the story was printed by Voltaire in 1733 in his "Lettres sur les Anglais", which appeared in an English version in the same year. The point seems of sufficient interest to warrant this note. The publication by Voltaire in 1733 makes the omission in the first edition of the "Elémens" still stranger.

ABSOLUTE TIME AND SPACE

By DR. G. BURNISTON BROWN
University College, London

"Yet the thing is not altogether desperate."
—NEWTON.

SINCE the last centenary of Newton's birth, his philosophy has been assailed with more vigour than in any other period since the first. Those who defended him against the Continental mathematicians of that time used the robust language of their day: James Bernoulli was a "boasting mathematical bully"; Leibniz "as dogmatical as if he had been originally one of God Almighty's privy council", and so on. In the tercentenary year, it may be worth while to inquire anew into the position of two of Newton's postulates which have come most under fire from Continental attack.

Absolute time, Newton thought it necessary to distinguish because the "vulgar" were liable to associate time only with the periodic behaviour of certain material systems. But the sensation of the passage of time is independent of the motion of any particular object and so the definition of time could not be made in terms of such a motion. Periodically recurring mechanical phenomena had, of course, to be used in order to introduce numbers as symbols for time intervals experienced in consciousness (Newton mentions the day and year, and Galileo used his pulse and water clocks); but these intervals were corrected according to theory built upon the assumption (in the case of the large time intervals) and the conscious awareness (in the case of the shorter ones) that the corrections, if any, would be very small. In this way laws were discovered which enabled a time scale to be developed which is independent of the behaviour of any particular body in the universe. This is the time scale which we still use to-day, and is possibly what Newton had at the back of his mind when he distinguished between "absolute, true, and mathematical time" and "relative, apparent, and common time".

Absolute space was postulated by Newton as existing, like absolute time, "without regard to anything external". Absolute motion is the translation of a body from one point to another in absolute space, and absolute motion may be distinguished by its "properties, causes, and effects". Newton's illustration of the water in the rotating bucket is well-known. This experiment shows that relative rotation of a small adjacent mass (the bucket) produces no centrifugal force on the water, but it does not altogether rule out the relative motion of distant large masses (the stars). This is emphasized by Newton's critics, but they do not tell us that Newton saw the difficulty himself and suggested a test which would decide the matter. That is why the position "is not altogether desperate". Newton suggested that "two globes, kept at a given distance one from the other by means of a cord that connects them", should be revolved about their common centre of gravity, and the tension in the cord measured when they were alone in an "immense vacuum", and then again measured when they were surrounded by "some remote bodies—that kept always a given position one to another, as the fixed stars do in our regions". If the force remained unaltered, we could conclude "the motion to be in the globes, and the bodies to be at rest"[1].

Physicists may vary in their opinion as to the result of such a test, but although the experiment is impracticable (unless the recession of the galaxies were to produce some change over a long period), it is not meaningless. It is curious, therefore, that Mach should quote pages from the "Principia" and yet stop quoting at the very point where the description of the crucial experiment above begins[2]. Continental relativists have followed Mach in ignoring this part of the "Principia" and they advance an epistemological argument saying that only "observable facts of experience" can be used as causes[3]. This would seem to rule out most of the causes used in physical theory, including the electron and the Heaviside layer, but without pursuing this point let us see what cause is put in the place of Newton's absolute space.

According to these critics, the cause of the bulging of rotating bodies must be distant masses. The use of the word 'must' looks as if they have left the inducto-deductive empiricism of Bacon and Newton and have returned to the compulsive categories of medieval logic. Misunderstanding Newton's famous "Hypotheses non fingo", some accuse him of not carrying out his own precepts. It is interesting to examine how far their own procedure is better in this respect. Passing over the almost universal use of unobservable space-time as a cause and saying that the motion of bodies is due to the curvature of space-time, let us ask whether these 'distant masses' can be observed. There are, of course, the 'fixed' stars, and the critics seem to conclude immediately that they are the distant masses the presence of which is compelled by their 'law of causality', and the relative motion of which produces centrifugal force.

Now Einstein's law of gravitation allows us to calculate the effect of relative motion on the force between masses, so that the next step was obviously to see whether the hypothesis of the relative motion of the known stars was sufficient to account for the bulge of the earth's equator. But for an examination of this point we have to turn to one of Newton's countrymen, and it leads to the conclusion that "the centrifugal force could not be produced by the motion of the stars, so far as they are known"[4].

Newton's absolute space is, therefore, not so easily dismissed, and the rather superficial epistemological 'principle of the law of causality' leads to the postulation of great masses for which there is no evidence in observation. It is true, of course, at the present time, that the larger the telescope the greater the number of distant stars seen, and thus it can be imagined that this number will increase, but those who hold such a law of causality cannot employ imaginary causes.

A choice philosopher in the tercentenary year of Newton's birth, when seeking for the reason for the bulging equator, must therefore choose between the following hypothetical causes: (1) The absolute space of Newton. The test which prevents it from being a physically meaningless concept cannot be performed. (2) The 'distant masses' of the relativists. The quantitative test which general relativity theory suggests shows that these distant masses are not the known fixed stars. These distant masses, therefore, are not 'observable facts of experience'. (3) The known stars. If the experimentally observed stellar masses are the cause, then the law of gravitation is not that of the general theory of relativity.

The problem of centrifugal force remains a fascinating one, and if the third cause above is ultimately adopted, it will certainly take a good deal of believing. This is because, if relative motion of masses be the cause, then masses at millions of light-years distance must be supposed to be effective whereas neighbouring masses produce no observable change. The behaviour of a gyrocompass in a submerged submarine is quite unaffected by the large masses of sea-water with various relative motions by which it is surrounded, and yet we must suppose it sensitive to the spiral nebulæ, α Piscium, β Leonis, γ Cygni, δ Herculis, ε Tauri, plus old Ursa Major and all!

To Newton, God was the origin of all things and "by existing always and everywhere, he constitutes duration and space". In Newton's mind the notions of absolute time and absolute space were undoubtedly mixed with pious considerations which no longer enter natural philosophy. Yet if absolute time means time the intervals of which are independent of the motion of any one body in the universe, and absolute space means a referent which is not obtained by taking any one body of the universe as being at rest, then absolute time and space are still the foundation of physical measurement to-day.

A NATIONAL SCHEME FOR HOLIDAY CENTRES

In the broadsheet "Planning for Holidays" (No. 194), Political and Economic Planning directs attention to a problem which may easily become acute, if not dangerous, immediately after the War, unless at least some effort is made to handle it now. The subject of holidays with pay enters into industrial relations, education and the social services, as well as forming an important part of a national health policy.

Only about four million out of about 18½ million insured workers in Britain in 1937 were entitled to holidays with pay, with about 750,000 salary earners with more than £250 per annum, but by March 1938 the number of insured workers with paid holidays had risen to about 7¾ millions, and when the Holidays with Pay Act was passed in July 1938, the Government's policy was that, after an interval to allow the extension of holidays by collective agreements, legislation should be passed in 1940 or 1941 making paid holidays compulsory throughout industry. The number of persons actually taking a holiday of one or more weeks away from home in 1937 has been estimated at about 15 millions out of a population of 46 millions. For the immediate post-war period, an estimate of 30 million holiday-makers in the first year after the War and towards 45 millions in successive years is not unreasonable. To meet this demand, holiday accommodation must be increased and an effort made to alter both the custom and the necessity which now concentrate the holiday exodus from the towns in the months of July and August, and especially in the Bank Holiday week. The potential peak of five millions seeking accommodation at one time could, it is estimated, be reduced to between 2 and 4 millions by spreading holidays between May and October.

The staggering of holidays is also important in its bearing on the cost of accommodation, but staggering is primarily a matter for industrial co-operation and for the help of the education authorities in timing school holidays. Moreover, forethought and planning will also be required if the greater demand for holidays is to be prevented from doing irreparable harm to the countryside and seriously interfering with the enjoyment of all. The War, by halting the spoliation of the coast of Britain, for example, has offered an opportunity of checking it permanently.

The urgency of this aspect has been stressed in the second report of the Coastal Preservation Committee, which appeared last October. The preservation of the coast is regarded as an essential item in a national policy for maintaining the beauty of the country; the scientific interest of the coast is an additional reason for its protection. Such preservation cannot be effectively carried out by the local authorities, and the report is in full agreement with the Scott report as to the necessity for immediate national planning, and that coastal preservation should be primarily a responsibility of the State. Coastal planning should include a belt extending sufficiently far inland to preserve the natural features of the general coastal landscape. There should be adequate provision for public access both to and along the shore and coast. Further, the right of the public to the free enjoyment of the foreshore for general recreation should be legally and practically established. Due allowance in planning the coastal belt should be made for probable losses through erosion, and the interference with public access to coastal areas for national defence purposes terminated as soon as military necessity allows.

According to the Planning broadsheet, the immediate post-war problem of holiday accommodation could be met by the conversion into holiday centres of some of the industrial hostels and other suitable war-time Government sites. The former include the Royal Ordnance Factory hostels, with a possible maximum of more than 41,000 places; the industrial hostels controlled by the National Service Hostels Corporation, with nearly 40,000 projected places in fifty-eight hostels; the temporary hostels outside target towns to house temporarily bombed-out workers and families with more than 50,000 places in seventeen hostels; and the three hundred rural hostels for agricultural workers with about 12,000 places. Although much of the accommodation will be in places not well chosen for holidays, more than half may be in suitable districts, and while other claims of comparable social importance may be advanced, it is hoped that a fair proportion will be allotted for holiday centres.

It is estimated that the Service camps have a capacity considerably exceeding that of any other type of war-time accommodation. Some of this will be retained for Service use, but some of the land occupied will be too valuable to retain for camps. Of the rest, much will be unsuitable for holiday requirements, but there should be a considerable useful residue adapted for temporary or permanent holiday use. Another possible source is in the large country houses no longer inhabited by their traditional owners, the expense of upkeep of which may prove progressively onerous. If the State were to acquire them, they could be maintained as people's holiday centres, a house forming a nucleus with annexes in the grounds if necessary.

The new holiday centres might be placed under the management of a semi-public body of the type of the National Camps Corporation or the National Service Hostels Corporation. Such a National Holiday Centre Corporation would be responsible for maintaining good standards of holiday provision at minimum prices at the centres under its control. Various forms of management might be tried experimentally, including indirect management through non-profit holiday organizations which would be free to run the centres in their own way, subject to inspection and to general conditions as to charges and standards. The Corporation might be assisted by an advisory committee representing the consumers and the experience of voluntary bodies concerned with workers' holidays.

COLONIAL RESEARCH IN THE BRITISH EMPIRE

THE survey of Colonial research in the British Empire prepared by Dr. Lucy Mair (*Agenda* for October) is of particular interest at the present moment. Under the Colonial Research Committee appointed in June 1942, a comprehensive survey is at present being made, as the first work of the Committee, of the facilities existing in Great Britain and the Colonial Empire, both for research and for the training of research workers. Pointing out that research in the Colonial field has tended in the past to be directed to the overcoming of practical difficulties that have already been encountered, Dr. Mair emphasizes that the present demand for a planned and consciously directed welfare policy is not a demand for something entirely new, but for more effective measures in the pursuit of aims already accepted. In regard to research by administrative officials, while those responsible for the conduct of policy in the Colonial Empire are fully aware of the need for knowledge of every aspect of the lives of its native populations, such inquiries, often limited in scope by the difficulty of finding time for them amid the pressure of other work, and carried out by those who have no specialized training in research in the elevant subjects, have not had a scientific value on level with that of work done by trained specialists evoting their whole time to research.

In social anthropology, the London School of Economics, where B. Malinowski held the chair rom 1926 until 1942, is the centre for this work in Great Britain. A great expansion in research was made possible by the Rockefeller Foundation which, after adding social anthropology to the subjects qualifying for its research fellowships, made a enerous grant to the International Institute of frican Languages and Cultures. The latter body om 1931 until the outbreak of war played a leading art in financing the training of social anthropologists and research by them in Africa. Chairs of ocial anthropology have been founded at Cape own and Sydney, and research workers trained at hese universities, and also at the Department of African Studies of the University of the Witwatersnd, have undertaken field-work in the adjacent olonial areas of Africa and the Pacific. While such ild-work is in suspense, a special advisory board in olonial studies constituted in 1941 has undertaken review for the University of London of the achievements and potentialities of the various social sciences in regard to Colonial research.

At the London School of Economics a Colonial Research Division has been set up to co-ordinate work on the various subjects which have Colonial aspects. Linguistic research in Colonial areas of a most practical kind is the work of the School of Oriental and African Studies (University of London), while the Colonial Department of the University of London Institute of Education has as its primary object the training of teachers for work among Colonial peoples but has also encouraged research on educational problems. The Oxford University Social Studies Research Committee organized in 1938 a co-operative expedition to Kenya, in which two anthropologists, an expert in Colonial administration, an economist and a geographer collaborated. The principal centre at Oxford for sociological research on Colonial questions is now Nuffield College, where a programme of research has been organized including a study of the economic problems of Nigeria and the Gold Coast, a comparative study of the various political institutions which have been developed under British rule in tropical Africa, and a study of the institutions, official and unofficial, through which economic policy is formed and executed.

In addition to the universities, the International Institute of African Languages and Cultures was also in peace-time an important institution for the organization of sociological research in Africa, and the war has prevented the completion of a plan to establish in Northern Rhodesia a Rhodes-Livingstone Memorial Institute as the first centre in Africa itself for the special study of problems arising out of the relations between local peoples and other races. Dr. Mair's survey also includes a brief reference to the London School of Hygiene and Tropical Medicine and the Liverpool School of Tropical Medicine, as well as to other medical research institutes in the Colonial empire where research in tropical medicine, in nutrition and in other health matters is carried out.

There are numerous institutions in the Colonies and in Great Britain which are concerned with agricultural and veterinary research and assist Colonial research workers with information and technical advice. Fishery departments have made surveys of local resources in Palestine and in West Africa, while in Malaya the Fisheries Department has concentrated its attention on raising the efficiency of this native industry. In the Colonial empire the most extensive forestry research has been done in Malaya by a well-equipped Forest Research Institute. The principal centre for forest research in Great Britain is the Imperial Forestry Institute at the University of Oxford, while research on the utilization of forest products is carried out by the Forest Products Research Laboratory, Princes Risborough, and the Colonial Forest Resources Development Department. A considerable amount of research has been carried out on the mineral resources of most Colonies by the geological departments, as well as by mining and oil companies, and this work has the assistance of the Mineral Resources Department of the Imperial Institute. At the present time, research on technical subjects has run far ahead of the study of social and economic problems, and Dr. Mair suggests that the disproportion may be corrected by the influence of the new Colonial Research Committee, on which both the social and the natural sciences are represented.

EDDY CURRENT LOSSES IN SINGLE-CONDUCTOR LEAD-COVERED CABLES

In a paper entitled "Eddy Current Losses in Single-Conductor Paper-Insulated Lead-Covered Unarmoured Cables of a Single-Phase System" (*J. Inst. Elec. Eng.*, **89**, Pt. 2, No. 12; December 1942), Dr. A. H. M. Arnold gives the results of an experimental investigation made at the National Physical Laboratory on cables carrying A.C. at power frequencies. Measurements were made with single-phase current on two parallel, 1·4-sq. in. cables forming go and return conductors. The total eddy-current losses are divided into four parts, namely, skin effect in the core, proximity effect in the core, proximity effect in the lead sheath, and circulating-current losses in the lead sheath when they are bonded together. Each of these is dealt with separately on a theoretical basis, and formulæ are then put forward for estimating the A.C. resistance of a cable from the design data; these formulæ are shown to give good agreement with the experimental figures.

The report is an official communication (Ref. *F/T78a*) from the British Electrical and Allied Industries Research Association and, together with an earlier one (Ref. *F/T55*), permits the following general conclusions to be drawn.

The losses in the core due to spirality effect and in the sheath due to skin effect can be neglected. The loss due to skin effect in the core is substantially the same as that due to skin effect in a solid round conductor of the same D.C. resistance per unit length, and was found to be calculable to within 1 per cent of the total losses by means of a well-known formula. The loss due to proximity effect in the core is less than that due to proximity effect in a solid round conductor having the same D.C. resistance per unit length on account of the higher resistance offered to the proximity eddy currents in a cable which have to flow from strand to strand. A previous formula for proximity effect in solid rods may be used for stranded conductors, provided a conductivity lower than the true conductivity of the copper is assumed; a figure of about 75–80 per cent of the true conductivity should be assumed.

A theoretical formula by H. B. Dwight for the losses due to proximity effect in the lead sheath was found not to be sufficiently accurate on account of its neglect of the modification due to the proximity effect in the core. An empirical factor has been added to Dwight's formula which increases its accuracy considerably. The loss due to circulating currents in the lead sheath was found to approximate closely to that obtained from the formula given in the report, except for cables very close together. At close spacings, the actual loss is less than that calculated, on account of the reduction of the mutual inductance between core and sheath due to proximity eddy currents in the core. This loss reduction can be allowed for largely by assuming that the proximity loss in the lead sheath is non-existent when the sheaths are bonded together.

The complete formulæ put forward for estimating the total losses in a cable, with the sheaths bonded or unbonded, give good agreement with the experimental results. At a frequency of 50 c./s., the maximum discrepancy between the computed and measured losses is less than 1 per cent for a 1·4-sq. in. cable, and at 100 c./s. the maximum discrepancy is 3 per cent. Tables are given by means of which the ratio of A.C. losses to D.C. losses of any standard cable can be read at a glance for the standard frequency of 50 c./s.

FORTHCOMING EVENTS

Monday, January 18

ROYAL GEOGRAPHICAL SOCIETY (at Kensington Gore; London, S.W.7), at 8 p.m.—Capt. W. E. D. Allen: "Ethiopian Highlands".

Tuesday, January 19

INSTITUTION OF CIVIL ENGINEERS (RAILWAY ENGINEERING DIVISION) (at Great George Street, Westminster, London, S.W.1), at 2 p.m.—Mr. George Ellson: "Modern Trend of Railway Engineering Practice".

Wednesday, January 20

FOLK-LORE SOCIETY (at the Royal Anthropological Institute, 21 Bedford Square, London, W.C.1), at 1.30 p.m.—Dr. J. D. Rolleston: "The Folk-Lore of Children's Diseases".

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, W.C.2) at 1.45 p.m.—Prof. W. E. S. Turner, F.R.S.: "New Uses for Glass".

INSTITUTE OF PHYSICS (at the Royal Institution, Albemarle Street, Piccadilly, London, W.1.), at 6 p.m.—Dr. R. K. Schofield: "The Distribution of a Liquid in a Pore-Space."

Thursday, January 21

INSTITUTE OF FUEL (JOINT MEETING WITH THE CHEMICAL SOCIETY, THE INSTITUTE OF CHEMISTRY AND THE SOCIETY OF CHEMICAL INDUSTRY) (in the University Chemical Department, Woodland Road, Bristol), at 5.30 p.m.—Dr. E. W. Smith: "Fuel Economy and the Chemist".

Friday, January 22

INSTITUTION OF MECHANICAL ENGINEERS (at Storey's Gate, St. James's Park, London, S.W.1), at 5.30 p.m.—Mr. S. A. Couling: "Practice and Experience in the Production of High-Speed Helical Gears, *with special reference to the Elimination of Transmission* Noises".

APPOINTMENTS VACANT

APPLICATIONS are invited *for the following appointments* on or before the dates mentioned:

LECTURER TO TEACH CHEMISTRY in the Department of Chemistry and Metallurgy, Coventry Technical College—The Director of Education, Council House, Coventry (January 20).

EDUCATIONAL PSYCHOLOGIST—The Secretary, Royal Victoria and West Hants Hospital, Bournemouth (January 22).

SPEECH THERAPIST for Speech Clinic in Harrow—Mr. C. W. Radcliffe, 'R.2', Clerk to the County Council, Guildhall, Westminste London, S.W.1 (January 23).

TEACHER OF MECHANICAL ENGINEERING—The Principal, Wolverto Technical College, Wolverton, Bucks (January 25).

BOROUGH ELECTRICAL ENGINEER AND MANAGER—The Town Clerk Municipal Offices, Grimsby (endorsed 'Borough Electrical Enginee and Manager') (January 28).

SPEECH THERAPIST—The Director of Education, Peel Stree Huddersfield (January 30).

EDUCATIONAL PSYCHOLOGIST—The Secretary-Superintendent, Belfast Hospital for Sick Children, 180 Falls Road, Belfast (February 1

ASSISTANT TO TEACH MATHEMATICS—The Registrar, Wimbledo Technical College, Gladstone Road, London, S.W.19 (February 1).

SPEECH THERAPIST—The Acting Director of Education, Educatio Offices, Becket Street, Derby.

REPORTS and other PUBLICATION

(not included in the monthly Books Supplement)

Great Britain and Ireland

Proceedings of the Royal Society of Edinburgh. Section A Mathematical and Physical Sciences. Vol. 61, Part 3, No. 2 Sylvester's Unravelment of a Ternary Quartic. By W. L. Edg Pp. 247–259. (Edinburgh and London: Oliver and Boyd.) 1*s*. [28

Transactions of the Royal Society of Edinburgh. Vol. 60, Part No. 18: The Conducting System of the Marsupial Heart. By Pr D. M. Blair, Prof. Francis Davies and Dr. E. T. B. Francis. Pp. 62 637+2 plates. (Edinburgh and London: Oliver and Boyd.) 1*s*. 9 [28

A WORLD AUXILIARY LANGUAGE

It has been well said that all men desire peace but very few desire those things which make for peace. Among "those things" must be placed an international auxiliary language which, though of almost hoary antiquity, has never interested more than a fraction of civilized mankind. The reasons for this apathy are many, but among the chief are : the imbalance between the self-assertive and combative instincts and the gregarious and co-operative instincts ; mental sloth ; patriotic bias ; and the obduracy shown by innovators in resisting reforms.

Civilized nations have already adopted common signs and code languages for use in mathematics and science, music, marine flag-signalling and wireless messages. No one would suggest to-day that people of differing nationality should employ different languages for such purposes, and thus it is that musicians can play from scores produced by other nationals. Ships' officers can send messages of considerable length and complexity by means of Morse and other signals. All nations understand the same numerals, the same chemical, mathematical and other technical signs. But, when the users of these convenient inventions wish to communicate by word of mouth or in writing, they are often unable to do so unless they happen to understand the same language. Is it not time that this state of affairs was abolished, and international intercourse put on a basis of facility and fluency ? The modern world is, indeed, somewhat behind the Middle Ages, when a sort of conversational Latin provided a means of direct communication between educated people. Despite Hegel's dictum that history teaches only that history teaches nothing, it seems more than likely that when the present War ends we shall see a strengthening of democratic ties and tendencies and a revival of the international language problem, just as we did after the War of 1914–18. The subject has already been raised by Sir Richard Gregory (NATURE, 150, 622 ; 1942), in the report of the British Association Committee on Post-War University Education (NATURE, 150, 716 ; 1942) and elsewhere.

The history of the movement is too long to justify more than a passing notice of a few of its salient features. The first recorded attempt to construct a world language was made some six hundred years ago by the Abbess Hildegarde, of Rupertberg, near Bingen. She devised a system with an alphabet of thirty-two letters on lines which did not appear again until the latter part of the nineteenth century. Then followed Descartes, in 1629, who elaborated a series of conditions which any universal language must satisfy. He had in mind a philosophical language not linked to natural languages ; and this was also the conception of Leibniz, who invented a system of classifying ideas into main groups and sub-divisions, using numerals allied with nine consonants and five vowels as symbols, and thus in a measure anticipating the modern Dewey system of library classification. Leibniz also appears to have been the first to foresee the possibility of a synthetic language constructed from word-roots in natural languages. In 1795, the third year of the French Revolution, Delormel presented to the National Convention a project based on the decimal system, which aimed at "uniting the peoples by the delicate bonds of brotherhood" through the medium of a common logical and regular language, because "national languages present at each step irregularities which make them difficult and demand a long time to learn". Coming to more modern times, in the 1880's, J. M. Schleyer, a Roman Catholic priest, succeeded in constructing a new language, Volapük, by building it up from the roots of words in existing languages, but after some progress the effort failed because the grammar was very involved; it was very difficult to identify the distorted monosyllabic roots, and the inventor refused to countenance any attempt at reform.

In 1887 appeared a much simpler and more flexible language, Esperanto, which has lasted much longer and attained far more success than any of its predecessors. Esperanto derives its vocabulary almost entirely from Western languages, its grammar is very simple, its pronunciation euphonious, and it lends itself easily to the introduction of new words. There may be certain defects in it, such as the arbitrary choice of roots from existing languages, which makes Esperanto easier to read than to speak, but experience has shown that it is perfectly practicable: people attending Esperanto congresses from all parts of the world, and meeting for the first time, converse fluently in it. Propaganda has now been conducted systematically and intensively for about fifty years, and on the whole has not been seriously prejudiced by the efforts of rival bodies, like those professing Ido, Esperantido and Occidental. The number of people who speak Esperanto is estimated at 1½–2 millions, though there are no reliable statistical data on the subject.

In 1919 the International Research Council recommended the appointment of an international committee to investigate the question, and in the same year the British Association appointed the committee which, in 1921, reported in favour of a neutral synthetic language. In 1920 the subject was discussed at the General Congress of the World Union of International Associations, and a resolution in favour of Esperanto was passed, with one dissentient. In 1922 a report was presented to the Third Assembly of the League of Nations, which was in general agreement with the findings of the British Association Committee, except that it declared outright in favour of Esperanto. A Red Cross conference, held in 1921, also voted for Esperanto, and in November of that year the conference of the International Labour Office recommended to the administrative council of the International Labour Office that it should increasingly use Esperanto as a practical means for facilitating international relations. Governmental recognition and help has been accorded by Spain, Portugal, Bulgaria, Czechoslovakia, Germany, Austria, Finland, Brazil, China and Japan. In addition, numerous municipal, commercial and academic authorities have passed resolutions in its favour, and the Roman Catholic Church has on more than one occasion shown a friendly attitude. Among scientific bodies that have interested themselves in this language is the French Academy of Sciences, which in 1921 published a manifesto urging scientific workers to adopt it; it was signed by thirty-nine prominent members, including Berthelot, Lumière, Painlevé and the Prince of Monaco. But revolutions are not made by resolutions.

As an international language is essentially a democratic ideal, it is not surprising that when the Nazis came into power in 1933 they discountenanced the use of Esperanto; in fact, in 1936, Himmler issued a police decree ordering the dissolution of all international language societies in the Reich, and similar action was taken later in Austria and Czechoslovakia. When war came in 1939, international contacts were inevitably broken, but the ardent advocates of Esperanto have continued their efforts, though nothing has been heard of other language projects. The Army Education Service includes Esperanto among the subjects for postal study courses, and for several years past the Royal Society of Arts has held examinations in the language. It is, furthermore, taught in a number of schools, both primary and secondary, as a regular or optional subject.

As previously stated, the end of the present War may see a revival of interest in an international auxiliary language; if the outcome corresponds with our hopes, there will be a general resurgence of the democratic spirit, as opposed to the authoritarian, a greater recognition of the advantages of interdependence, and of the necessity for freer international trade and improved international communications. On the other hand, there is a danger that some of the liberated nations may be over-imbued with the spirit of nationality, that is, with patriotic bias, and will strive to maintain their independence, their institutions and their culture to a degree that will impair the spirit of mutual dependence (and especially if the proposal of federation does not fructify); but this impediment should not deter the adoption of a world language, if it be thoroughly understood that the language would in no case supplant an existing national language. A further impediment to realization would arise if any of the bigger nations were to insist on the general acceptance of its own national language. In the investigations made by the British Association Committee during 1919–21, it was found that with the exception of certain small countries in north-west Europe, commercial interests were all in favour of having their own national language adopted. This obstacle would be quite likely to arise among the Anglo-Saxon peoples, whose prestige and influence would be greatly enhanced by a successful war. The English language, with its obvious excellencies, is far too difficult for use as an international auxiliary language, and the general adoption of an easier but debased form of it would in the end debase the national language itself.

The problem, being essentially an international one, would best be handled by an international body, for example, a reformed League of Nations; but such a body would be effective only if it gained the full support of its constituent members, and therefore, apart from private enterprise, individual governments would have to take steps to stimulate public interest in the question and eventually to canvass public opinion. Though the final decision as to the desirability of an international auxiliary language, and the language to be adopted, would rest with the international authority, each national representative should be in a position to declare unequivocally in favour of that chosen by his own country.

The problem, therefore, resembles nearly all other problems relating to human betterment, in being fundamentally an educational one. It would primarily concern governmental education departments, and these would be guided by an impartial commission consisting of representatives of all the main national activities: industry and commerce, science and its applications, letters and linguistics, schools and universities, and the great professions. Once an international auxiliary language had been chosen, the question of how and when it should be introduced would arise, and also whether or when instruction in it should be made obligatory. If the language were really simple, its introduction into primary and secondary schools should not lead to further congestion of the curricula. As a rule the very young learn readily to speak a new language, if they live in an atmosphere of it, but they forget it soon, and often completely, when they have no further use for it. A thorough knowledge of a new language is usually acquired very slowly by school children up to about sixteen or seventeen years of age, but after then, especially if they see the need for it and are given facilities for practising it, acquirement is much more speedy. There is, therefore, much to be said in favour of the proposal made by the British Association Committee on Post-War University Education that the learning of an international auxiliary language would best be undertaken as a long-vacation study in the university (and presumably in evening classes by non-university students). But no lasting progress or success would be attained unless adequate facilities were provided for using the language, whether in reading, correspondence, or conversation, preferably with foreign people.

Those whose faith in a war to end war has been rudely upset, and those who hold that man's combative instinct is neither eradicable nor transformable, may yet be convinced of the practical utility of an international auxiliary language in everyday life. Research workers would surely welcome a single journal containing all the abstracts of original papers and also copies of important papers they may need in one international language; learned and technical societies could economize on the purchase of foreign literature; and the use of an international auxiliary language at international scientific congresses would enhance not only mutual comprehension, but also the good-fellowship that has been so marked a feature of such gatherings in recent years. The end of the present War should provide a unique opportunity for translating into effective practice this six hundred year old ideal.

DYNAMICS OF THE STELLAR SYSTEM

Principles of Stellar Dynamics

By S. Chandrasekhar. (Astrophysical Monographs sponsored by the *Astrophysical Journal*.) Pp. x+251+6 plates. (Chicago: University of Chicago Press; London: Cambridge University Press, 1942.) 5 dollars.

As a subject progresses the attractive simplicity of the early researches gives place to laborious elaboration. In the last three years, Dr. Chandrasekhar has been very active in the mathematical development of stellar dynamics. The trend of his work may be judged from the fact that one contribution alone contains more than 1,800 numbered formulæ. There is no denying that this heavy method of attack can be justified; but it leaves us with the depressing feeling that the subject which began thirty years ago as a joyous adventure has reached a stage of uninspiring ugliness. We are the more grateful to Chandrasekhar that in his new book he has not allowed the subject to be crushed by an overweight of mathematical formulæ. The treatment is, of course, mathematical throughout; but it is mathematics of the methodological kind which the reader tolerates, not heavy algebra which he skips. The book fills an obvious gap in astronomical literature, and it should give a valuable stimulus to research. There are some omissions to which reference will be made later; but, if judged by what it contains rather than by what it leaves out, it is a very helpful synthesis.

There are five sections, dealing respectively with stellar kinematics, the rate of approach to statistical equilibrium, the main problem of the dynamics of a galaxy, the theory of spiral structure in galaxies, and the dynamics of star clusters. The treatment is usually well arranged. I have, however, one complaint to make. The author follows the practice of continually introducing fresh symbols, and his final formulæ are left in whatever stage of symbolism he happens to have reached. Consequently his results are usually cryptograms, of which the key has been cut up into little pieces and hidden in odd corners. This may not incommode the systematic reader overmuch, but a reviewer can only judge the progress that has been made by the enunciations of the problems solved; what the results amount to, and whether they reveal anything unexpected, he has no idea, since the author does not choose to tell him.

I shall here deal more particularly with the middle section on the dynamics of the galaxy, which is perhaps the most open to criticism. It seems to me to suffer from the lack of a defined practical aim, such as an observational result to be elucidated. The early development of galactic dynamics came about in a practical way. There were two rival views as to the nature of star-streaming—Kapteyn's hypothesis involving transverse streaming and Turner's involving radial streaming. Turner's hypothesis was less artificial, and the radial direction of streaming is now known to agree with observation; but it raised difficult dynamical questions—whether the radial orbits would involve an impossibly high congestion of stars at the centre, or whether the data would demand too eccentric a position of the sun. Even if no new questions suggest themselves to-day, the bearing of galactic dynamics on these older problems might well have been treated, especially because there has in the meantime been a great change in our knowledge of the dimensions and rotation of the galaxy. For example, Chandrasekhar rightly points out a fallacy in a theorem which I gave in 1915; and the correction makes the conclusion (that star-streaming in a steady system is necessarily radial) less general than has hitherto been supposed. But he does not take the opportunity of restating the position. Presumably it is still true that in a steady system with axial symmetry the velocity surfaces are confocal quadrics, and transverse star-streaming is rigorously excluded; but there is no mention of this. Again, later investigators have considered an expanding or contracting system especially with the view of explaining the apparent discordance between the vertex of star-streaming and the direction of the galactic centre; Chandrasekhar also admits a variation with time, but makes no reference to this question.

In galactic dynamics the stars are considered to move in the smoothed field of gravitational attraction of the system as a whole, the statistical effect of encounters being negligible. This formulation now seems so obvious that it may be forgotten that it was not the first stage of stellar dynamics. The fact is that the analogy between stars and the molecules of a gas was too enticing; and what was first looked for was an equipartition of energy. Misleading observational evidence of a correlation between masses and velocities of stars seemed to support this. The fallacious analogy might have endured much longer, but for the discovery of 'moving clusters' in which the stars have equal and parallel motions although they are widely separated in space. The most impressive of these is the Ursa Major cluster, which comprises stars in other parts of the sky, including Sirius. The realization that the time of relaxation to statistical equilibrium is extremely long (10^{14}–10^{16} years) was one factor in the change; another factor was the realization that the time of relaxation to dynamical equilibrium is remarkably short (10^8–10^9 years). We were thus led to contemplate the stellar system as dynamically in a more or less steady state, changing very slowly towards the ultimate statistical equilibrium, or more strictly towards an ultimate collapse and dispersal. But the most important factor which led to the formulation of galactic dynamics was that urgent questions relating to the star-streams demanded such a theory.

The obvious problem is to determine the possible states of motion of a galactic system governed by its own gravitational field. So far as I am aware, no solutions have been found except for a distribution of density with spherical symmetry; but this soluble case, besides being rather attractive mathematically, helps us to gain a better understanding of the whole subject. Although the progress has not been very great, it is scarcely justifiable to ignore it altogether. I do not think that Chandrasekhar even mentions the problem, at any rate in the section on galactic dynamics.

The problem which Chandrasekhar handles is one that was originally formulated by the reviewer in 1915 as a side-problem, namely, a sub-system moving in the controlling field of a larger system. Looming behind it, there is always a further problem as to how the equilibrium of the larger system itself is maintained; in particular, there is the question whether the particular gravitational field which the sub-system demands is such as could be furnished by any admissible form of larger system. Thus the theory is better adapted to prove that certain kinds of distribution (for example, transverse star-streaming) are impossible than to prove that certain kinds are possible. In short, the 'solutions' satisfy necessary, but not sufficient, conditions for physical application. The view of galactic structure current in 1915 gave reasons for treating a sub-system, with density distribution markedly different from that of the stars as a whole, which do not apply to-day; and the primary justification for the 'side-problem' seems to have disappeared. Nevertheless, it is probably the most practicable way of approaching the main problem of an oblate galaxy. I think that Chandrasekhar's most important advance is to show that, if differential rotation exists, the sub-system can only be in a steady state if the potential of the controlling system has axial symmetry. It is interesting to notice that the recognition of galactic rotation, which might seem to be an unwelcome complication in a problem which already over-taxes our powers, actually makes for simplification, since his theorem ceases to apply when the rotation vanishes.

The dynamics of a star gas and of an atom gas are strongly contrasted; but the complete theory of the galaxy must include them both. For the galaxy comprises a stellar system and a cosmic cloud. It is still uncertain which part has the greater mass. It has generally been assumed that the stellar system is the more massive; but if it turns out that the main part of the controlling gravitational field is due to the cloud, the problem of the equilibrium and evolution of the galaxy will be substantially modified, and presumably simplified. In either case there is an important condition which galactic dynamics ought to take into account. Although the star gas and the cosmic gas are semi-independent systems governed by widely different forms of dynamics, the rotation (both absolute and differential) is known to be approximately the same for both. It would seem, therefore, that the distribution of rotation has to be compatible with both kinds of dynamics. It is just possible that, so far as the practical problem is concerned, we have been beginning at the wrong end; and the true starting point should be a study of the forms of distribution of a rotating viscous gas.

A. S. EDDINGTON.

FRUIT CULTURE

Modern Fruit Production

By Prof. Joseph Harvey Gourley and Prof. Freeman Smith Howlett. (Rural Text-book series.) Pp. vii+579. (New York: The Macmillan Company, 1941.) 18*s.* net.

THIS book is quite frankly written for the professional horticulturist, the serious student and the progressive grower of the United States. But a study of the book shows how extremely diverse are the environmental conditions experienced on that continent and what a wide range of fruit—from berry fruits to grapes and from citrus to cherries—comes within its purview.

The authors fully realize the vastness of the industry for which they are attempting to cater, and point out that the United States was responsible over a six-year period (1931–36) for the production of no less than one third of the world fruit output. Very wisely, therefore, they make no attempt to present a mass of experimental data which would but serve to bewilder. Actually only fifty short tables in all appear on the 565 pages of exposition of general principles. There are in addition some eighty-seven pertinent diagrams and plates, which latter give a very good idea of the diversity of fruit-growing methods practised in the United States.

While the book contains more than seven hundred specific references to recent research, these are skilfully dovetailed into a clear account of up-to-date American practice. Where research in other countries, especially in Great Britain and the Dominions, bears upon general horticultural principles, it is not infrequently quoted. Although it is claimed that "Pomology has developed into a science in its own right, similar in its fundamental background to other plant sciences", the difficulties of drawing conclusions of universal application upon complex, long-lived, extensive-rooted fruit plants, so subject cumulatively to environmental influences, are frankly stated. The authors put an unanswerable case for the abandonment of a search for rule of thumb methods and stress the need for an appreciation of all the interdependent factors which alone can guide cultural practices from year to year. The complexity of the factors involved in such problems as fruit bud formation, fruit set, alternate year bearing and storage quality is clearly brought out, and the relationship of the orchard practices of pruning, cultivating, manuring and fruit thinning—which are designed to control these tendencies—is developed in parallel. Indeed no one can read the chapters dealing with these subjects without feeling more competent to deal with the practical problems and more conversant with the underlying principles. For example, while the classical experiments of Kraus and Kraybill on the carbohydrate nitrogen relationships in the fruiting tomato plant are brought into line with Hooker's investigations on flower formation in the apple for the benefit of the student, the fruit grower is assured by the practical conclusion that it is the leaf surface of the plant which is of paramount importance in bud differentiation, and he is directed to the alternative ways of maintaining or improving leaf surface, which can be appropriately chosen according to the condition of his orchard. The investigator is tempted to explore further the suspected presence of flower-producing hormones.

The arrangement of the individual chapters is somewhat puzzling to the European who, after reading Chapter 2 dealing with the "Fruit Plant and its Parts", is surprised to find that "Propagation and Stocks" are relegated to Chapter 15. Again, after reading about "Cultural Practices", "Fertilizers and Manures" and "Water Relations" in Chapters 6–8, disappointment is experienced that bare mention is made of Wallace's pioneer work on the diagnosis of nutrient deficiencies by leaf and growth symptoms. However, a handsome tribute to that work is only delayed until Chapter 14 which, incidentally, includes a useful summary of the symptoms of other 'physiological disorders'. It is realized that these seeming discrepancies are due to local emphasis in a country where nitrogen and moisture deficiencies have in the vast majority of cases been the limiting factors in orchards, and where large-framed trees planted 32–40 ft. apart have been the unquestioned order of the day. A few more specific cross-references in the earlier chapters would, however, not come amiss.

Some readers will be surprised to learn what a comparatively minor role pruning is given in the orchard practice of the United States to-day, but the statement that many growers are now pulling out their apple trees at 30–35 years old because of the reduction of fruit size and quality suggests that the pendulum may have swung too far in the direction of *laisser faire*.

Except in so far as diseases, pests and measures for their control affect 'tree condition', the authors have made no attempt to deal with pathological problems; consequently they have been able to cover the pomological field very fully and there are few established facts or practices which they have overlooked. Thus "Modern Fruit Production" should succeed in stimulating a much wider audience than it was designed to inform, and it will be welcomed as a clear summary of progress made in correlating the recent findings of horticultural science with economic fruit-growing practice.

The data collected by the Bureau of Economics of the U.S. Department of Agriculture, and supplied in Chapter 1, about the varieties, ages and localities of some hundred million bearing and non-bearing apple trees in the United States, should give food for thought to the fruit industry of Great Britain, which has no reliable statistical basis upon which to reconstruct its future.

R. G. HATTON.

FOREST TREE SEED

Forest Tree Seed of the North Temperate Regions, with Special Reference to North America

By Henry Ives Baldwin. (A New Series of Plant Science Books, Vol. 8.) Pp. xvi+240. (Waltham, Mass.: Chronica Botanica Co.; London: Wm. Dawson and Sons, Ltd., 1942.) 4.75 dollars.

THE regeneration of forests depends, in the first place, on the seed of trees. The conditions which influence the production and germination of seeds, and the effects of environmental and hereditary factors on the nature of the plants they produce, and thus on the whole future of the crop, have been the subjects of extensive research and inquiry for many years. The results of original experiments have often a very limited circulation, reports are often published in obscure journals and the research worker and the practising forester have seldom either the time or the opportunity to search for them. It is, therefore, highly desirable that a synthesis and a digest of this extensive literature should be produced, and the present work meets this requirement very successfully.

A great deal of the interest in tree seeds has arisen from the expansion of artificial regeneration, afforestation and ornamental planting, so that it is not surprising that the greater bulk of this book is concerned with the artificial treatment of seeds, such as collection, storage, extraction, cleaning, testing, etc. Nevertheless, these are related to the reactions of seeds to their environment, and the author has kept this relationship to the forefront throughout.

The chapter on "Extraction and Cleaning" is particularly interesting. Descriptions of many kinds of apparatus are given, with diagrams, and the working of each is explained and commented upon, both from the point of view of their effect on the seed and their economic efficiency.

The subject of seed provenance is discussed in a chapter in which the work of investigators on some of the most important European and American species is summarized. To the British reader it is regrettable that that of Münch, Rübner and others on the European larch is not included, but a selection had to be made and, for American readers, this species is of minor importance.

Though the artificial treatment of seeds and the requirements of artificial regeneration receive so much attention, the author rightly stresses the fact that the problems of natural regeneration are also bound up with seed production, storage, dispersal and germination, as well as the influence of biotic, climatic and soil factors on the survival of seeds in a viable condition and on the establishment of the seedlings as independent organisms. All these matters receive consideration in this work. The method of the author is to devote a chapter to each branch of the subject, giving a general account of the points investigated by different workers, with a summary of the most important contributions. Then a general review of the position is given, indicating points on which agreement is reached and those in which further investigation is called for. A very full bibliography is added to each chapter. At the end of the book is a useful glossary of seed terms with their French, German, Danish, Norwegian and Swedish equivalents, and a list of authors mentioned in the text.

The work will be indispensable to research workers in the field of tree seed and very useful to practical foresters and members of the seed trade. It is not a handbook of tree seed, giving cut and dried information about individual species, but a reference book and a guide, not only to existing knowledge but also to the directions in which that knowledge should be extended in the future.

T. THOMSON.

NON-EUCLIDEAN GEOMETRY

Non-Euclidean Geometry

By Prof. H. S. M. Coxeter. (Mathematical Expositions, No. 2.) Pp. xv+281. (Toronto: University of Toronto Press, 1942.) 3.25 dollars.

THE philosopher Kant declared that Euclidean geometry was inherent in the human mind and expressed the truth about space. We now recognize that non-Euclidean geometry is equally valid as an abstract system, and that one particular form (due to Riemann) has more claim than Euclidean geometry to represent the properties of physical space. The transition from the old point of view to the new has revealed the true nature of geometry, and thence of mathematics in general, and has helped to build up the theory of relativity.

To survey their fields and build the pyramids, the Egyptians had a set of empirical rules, which the Greeks developed into a science. In particular, Euclid attempted to deduce the properties of straight lines and circles from certain definitions, axioms, and postulates. The axioms or "common notions" were regarded as self-evident truths, whereas the postulates were frankly assumptions, but most of them seemed so obvious that no one denied them. There was one exception, namely, the fifth postulate (often called the eleventh axiom): *If a straight line falling on two straight lines make the interior angles on the same side less than two right angles, the two straight lines, if produced indefinitely, meet on that side on which are the angles less than two right angles.* For centuries mathematicians, while not doubting the truth of this postulate, objected to it as too complicated. It was hoped to prove it by showing that a contradiction would arise from denying it or one of its simpler substitutes, such as 'Playfair's axiom': *Two intersecting straight lines cannot both be parallel to the same straight line.* No contradiction was ever found. In 1823 Bolyai, and independently Lobatschewsky in 1826, worked out a system of geometry (now known as hyperbolic) quite as logical as Euclid's, but assuming that his parallel postulate was untrue! Similar results had been obtained by Gauss even earlier, but for fear of ridicule he did not publish them.

A much greater departure from the Euclidean geometry appeared in 1854, when Riemann, using the methods of differential geometry which Gauss had developed from land-surveying, introduced a geometry (now called spherical) in which there are no parallels, and two straight lines enclose a space! The relationship between the alternative geometries remained obscure until much later. Cayley (1859) showed that the 'metrical' properties of Euclidean space, such as distance and perpendicularity, could be derived analytically from the 'projective' (that is, non-metrical) properties of a certain conic called the "absolute". Klein (1871) developed this idea, and set up a general projective geometry, from which he obtained elliptic geometry (akin to Riemann's), parabolic (Euclidean), and hyperbolic. He also showed the existence of 'models' or correspondences, by which it could be deduced that one geometry is logically self-consistent if another is so. (Dr. Coxeter thinks that the only ultimate test of consistency is based on the properties of the physical world as interpreted by our senses.) More searching investigations into the logical structure of geometry were made by Pasch (1882) and Hilbert (1901). The word "axiom" is now used for an assumption concerning the relationship between certain *undefined* terms such as *point* and *straight line*, and there are an infinite number of geometries corresponding to the infinite choice of the set of axioms, which may be freely chosen as long as they are self-consistent. Naturally, those which agree closely with the properties of physical objects are of most interest, in particular Euclidean geometry because of its simplicity, and Riemannian because of its use in relativity.

Dr. Coxeter's book starts with an excellent introductory chapter, mainly historical. Chapters 2 and 3 are on projective geometry, and instead of defining polarity with reference to a conic, follow von Staudt by defining polarity as "a correlation of period two" and then look for a corresponding conic. Chapter 4 is on homogeneous co-ordinates. After these somewhat prolonged preliminaries, elliptic geometry is obtained from projective geometry, since every axiom of the former is valid in the latter. This idea is developed in Chapters 5, 6 and 7. In Chapters 8 and 9, Euclidean and hyperbolic geometry are derived from a general 'descriptive' geometry. The remaining five chapters are simpler, dealing with hyperbolic geometry in two dimensions, circles and triangles, a general triangle of reference, area, and Euclidean models. The book concludes with a bibliography and an index. It will appeal to those who have already a first acquaintance with the subject and are ripe for a systematic treatment.

H. T. H. PIAGGIO.

Soils and Soil Management

By Prof. A. F. Gustafson. (McGraw-Hill Publications in the Agricultural Sciences.) Pp. viii+424. (New York and London: McGraw-Hill Book Co., Inc., 1941.) 21*s*.

THIS book sets out to describe the principles of soil management from a practical point of view in a way that should be intelligible to the modern farmer or to students taking advanced courses in agricultural colleges. The author covers the whole field of soil management including, on one hand, such subjects as soil cultivation, erosion control, dry farming and irrigation and, on the other, fertilizers, manures and crop rotation. He naturally chooses most of his examples from the United States and tends to emphasize points of importance to that country, but this restriction does not detract from the book's educational value for students outside that country, although some of the detail will naturally not apply.

The main criticism of the book is that the scientific principles underlying the practice are not always clearly brought out. This is especially unfortunate in those subjects in which there is no traditional background of knowledge to help the reader pick out those particular details of practice that would be applicable outside the agricultural regions described. A minor criticism is that the introductory chapters on what is often called soil science, namely, soil formation, soil micro-organisms, soil organic matter and soil water are too sketchy to be really helpful, and, in addition, that on soil water is not up to date. The main part of the book, on soil management proper, does not suffer from this latter defect. The subjects are treated fully, particularly on the practical side, and the text is illustrated with a large number of well-chosen figures. E. W. R.

The Riddle of Religious Education and a New Solution

By Adam Gowans Whyte. (Thinker's Forum, No. 22.) Pp. 48. (London: Watts and Co., Ltd., 1942.) 6*d*. net.

IN the course of an article which appeared in NATURE of November 14 last, the position was maintained that the omission from the religious instruction of senior pupils of all reference to faiths other than the Christian would be hard to justify in these times. Mohammedans and Buddhists, Hindus and Parsees, Jews and other non-Christians, are fighting on our side in a war of good against evil—a struggle for a way of life which for many of us, but not for any of them, finds its historical expression in the New Testament. This position is very strongly maintained in Mr. A. G. Whyte's ably and vigorously written pamphlet. The body of the pamphlet is devoted to a brief historical review of all that has led up to the "dual system" of control. The writer makes some apposite quotations from eminent Churchmen who have been quite unhappy about the working of that system. His "new solution" goes all out for making religious instruction broader and more objective. He maintains that a fraction of the time spent during a child's school life in expounding the details of the Christian creeds would suffice to convey an intelligent appreciation of the fundamentals of other creeds, and to engender a more sympathetic attitude towards the millions who share our essential aims.

Annual Reports on the Progress of Chemistry for 1941

Vol. 38. Pp. xxxii+326. (London: Chemical Society, 1942.) 15*s*.

IT would be unprofitable to attempt to crystallize an already highly concentrated essence, and indeed all that is required is a reminder that these valuable reports continue to appear without interruption. Work on diamagnetism in recent years is summarized with special reference to its relation to problems of molecular structure, and developments in the chemistry of the carbonyls and nitrosyls since 1934 are surveyed. A comprehensive report on organic chemistry deals with physico-organic topics, organometallic compounds, polysaccharides, synthetic polyenes, polyterpenes, natural quinone pigments, and heterocyclic compounds. That on crystallography relates to temperature effects in the reflexion of X-rays from crystals, and to metal, inorganic, and organic structures. Among the biochemical subjects discussed are the vitamins, particularly their assay, since it is now recognized that definite minimal quantities are needed to prevent deficiency diseases, and larger quantities to prevent subclinical deficiencies. In view of war-time restriction on the importation of fruits, the incidence of vitamin C in raw and prepared green vegetables is of special interest. Another topic is the utilization of carbon dioxide by bacteria and animal tissues. Analytical methods are reviewed, and the book closes with a chapter on radioactivity and sub-atomic phenomena, in which a historical introduction is followed by a survey of present knowledge of nuclear processes and of the concepts used in explaining and predicting them.

Reports of the Progress of Applied Chemistry

Issued by the Society of Chemical Industry. Vol. 26, 1941. Pp. 545. (London: Society of Chemical Industry, 1942.)

EXCEPT for an additional short section on starches, the chapters of this report correspond to those of the immediately preceding volume in the series. Vast as is the field surveyed, there can be no doubt that real progress is substantially greater, for much valuable information is necessarily being withheld from publication during the War. Many of the subjects discussed find emphasis, if not their origin, in the special demands of war-time needs; in this class are, for example, the manufacture of butadiene for synthetic rubber, substitute materials for ceramic products and the use of commoner in place of relatively rarer metals (as in the substitution of aluminium by zinc or tin-zinc alloy for milk-bottle caps). The section on plastics continues to reflect great interest and noteworthy progress, with an evermore complete fusion of "academic" and "technological" research. The supply of glycerin from soap manufacture can now be supplemented by its synthesis from propylene by way of allyl alcohol; and the physical properties of soaps and their solutions continue to attract much attention. In the section on sanitation and water purification there is reference to fluorosis arising from fluorine in drinking water: and there is quoted evidence that the incidence of goitre does not correspond to the iodine or the fluorine content of the water but may be of fungal origin. The year in review was marked by the pooling of research resources by five important drug manufacturers in Great Britain.

RESONANCE AND CHEMICAL REACTIVITY

By PROF. M. POLANYI
University of Manchester

OUR ideas on the mechanism of chemical reactions are still in flux, and the search for the most suitable conceptual framework continues. The following notes attempt a further slight shift in perspective, which seems to be well suited for surveying some of the more recent additions to this field of inquiry[1].

The nature of molecular structure has undergone in the last ten years a considerable degree of re-interpretation in the light of quantum-mechanical resonance. Wherever alternative bond assignments are possible—even though these may often seem of a rather remote and altogether speculative character—it now appears useful to take these into account and to represent the actual state of the molecule as resonating between all the component pure states.

We may extend this view by considering the initial and final states of a chemical reaction as alternative bond assignments of the same atomic system. In this sense, for example, $H_2 + I_2$ would be considered as one of the two pure states of which a system of 2H and 2I atoms is capable, the other pure state being represented by the alternative bond assignment HI + HI. Denote the eigen-functions characterizing the electron distribution in the pure initial and final states by ψ_i and ψ_f respectively, then the electronic distribution of the system is characterized in general by $\psi = \alpha_1\psi_i + \alpha_2\psi_f$. In these terms the chemical reaction signifies a continuous change of the coefficients α_1 and α_2, by which α_1/α_2, starting from very small initial values, achieves in the end values approaching infinity. The change can be seen to depend on the atomic co-ordinates. Take as an example the reaction

$$\underbrace{\mathrm{Na} + \mathrm{Cl}}_{x}\underbrace{{} - \mathrm{CH_3}}_{y(=y_0)} = \underbrace{\mathrm{Na} - \mathrm{Cl}}_{x(=x_0)} + \underbrace{\mathrm{CH_3}}_{y}$$

where y_0 signifies the normal bonding distance of C–Cl and x_0 the normal bonding distance of Na Cl. Initially $\alpha_1 \gg \alpha_2$ when x is large and $y = y_0$, whereas finally $\alpha_1 \ll \alpha_2$ when y is large and $x = x_0$.

We will suppose that—owing largely to the steric effects of the substituents attached to the central carbon—the reaction proceeds so that the distances x and y remain colinear, and making use of this simplified condition we will try to predict the activation energy of the reaction. Let E_i and E_f denote the energies of the pure initial and final states; and denote at the beginning of the reaction $E_i = E_i{}^0$, while at the end $E_f = E_f{}^0$. All the configurations of the atomic system which lie between these two stable configurations are necessarily unstable, and hence their energies lie higher than either $E_i{}^0$ or $E_f{}^0$.

Of particular interest among these unstable configurations are the 'transition states' in which $\alpha_1 = \alpha_2$, and for which the energies of the pure initial and pure final states coincide. The lowest of these is usually called '*the* transition state' or 'the activated complex' of the reaction, and the theory of chemical reactions consists mainly in attempts to predict the energy level of this state—by which the activation energy of the reaction is determined.

To obtain this level in our case, we introduce the further simplification that in the opening phase of the reaction the sodium atom can approach the chlorine atom to within the normal bonding distance x_0 without incurring appreciable repulsion. Hence we may imagine that the reaction starts with $x = x_0$, and that the x variable remains at this value throughout the reaction, while all the variations of the energy are determined by changes in y. In the pure initial state the variation of energy is seen to consist in the changes of the attraction energy (E_{iy}) of the chlorine-carbon bond; in the pure final state it lies in the changes of the repulsion energy (E_{fy}) arising between the chlorine and carbon atoms in the non-bonding state. Consequently we have $E_i = E_{iy}$ and $E_f = E_f{}^0 + E_{fy}$.

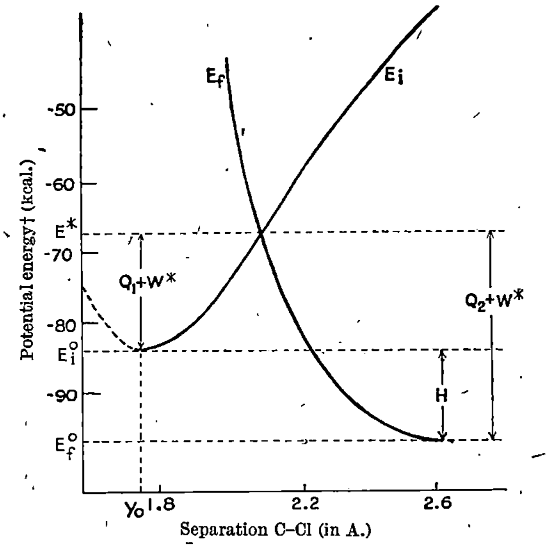

Fig. 1. MECHANISM OF REACTION
$\mathrm{Na} + \mathrm{Cl\,CH_3} = \mathrm{NaCl} + \mathrm{CH_3}$

E_i energy of extended C–Cl bond.
E_f energy of repulsion between H_3C and $Cl^-(Na^+)$ plus normal bond energy of NaCl.
y_0 normal bond distance C–Cl.
E_i^0 and E_f^0 energy before and after reaction.
E^* energy of transition state.
W^* resonance energy in transition state.
Q_1 and Q_2 activation energies of forward and back reactions.
H heat of reaction.
† Counted from level of free particles Na, Cl, CH_3.

By plotting both E_i and E_f as a function of y (Fig. 1) we find the point where their values coincide (E^*). This would represent the energy of the transition state, but for the fact that we have not yet taken into account the resonance energy which is bound to arise when a system of atoms can be represented by more than one bond assignment. This resonance energy will be negligible at the beginning and at the end of the reaction, and will reach high values only in the neighbourhood of the transition state. Therefore, if we define E^* as the energy at which levels of the pure states coincide, and call the resonance energy at the transition state W^*, then the activation energies Q_1 and Q_2 are defined by $Q_1 = E^* - E_i{}^0 - W^*$ and $Q_2 = E^* - E_f{}^0 - W^*$. Thus by determining E^* we can find $Q_1 + W^*$ and $Q_2 + W^*$, but not the values of Q_1 and Q_2 themselves.

However, in the case of Na + Cl CH_3 (and other 'ionogenic' reactions) it is possible to get a little further, without undertaking the difficult and uncertain calculation of W^*. An evaluation of the diagram in Fig. 1 for Na + Cl CH_3 yields $Q_1 + W^* =$

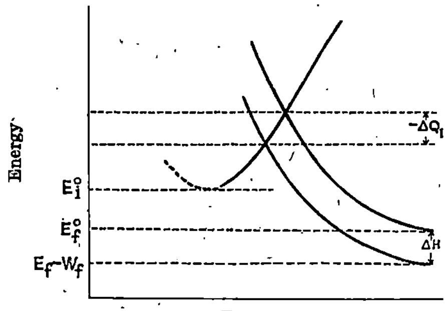

Fig. 2. CONNEXION BETWEEN CHANGES IN REACTION HEAT AND ACTIVATION ENERGY. ($\Delta H = W_f$ AND ΔQ_1 ASSUMED TO BE EQUAL TO ΔE^*).

16 kcal., whereas Q_1 observed[2] is 10 kcal. Thus W^* appears to be not excessively large, and we may well try to analyse the effect of replacing methyl by other radicals in the hope that the effects of such variations on W^* may be small or at least not entirely unpredictable. Take first a radical like allyl or benzyl, which resonates in the free state, whereas resonance is absent in the corresponding molecule. This causes a depression of the energy of the final state by the amount of the resonance energy W_f, the heat of reaction H being increased by $\Delta H = W_f$ (Fig. 2). The pure final state will be affected throughout in this sense and the E_{fy}-curve will be shifted bodily downwards—as shown in Fig. 2—by the amount W_f. The result is to depress the level E^* by $\Delta E^* = -\alpha W_f$, where α is a fraction depending on the angles of inclination at the crossing of the E_i and E_f curves. The value of α obtained from the diagram for our case is about 0·27.

We may add another relationship for the case that it is the R–Cl molecule which resonates whereas this time resonance is absent in the free radical. Vinyl chloride and chlorbenzene are compounds reliably assumed to be of this kind[3]. We may expect here a reduction of the heat to the extent $-\Delta H = W_i$ and also a corresponding elevation of the level E^* by $\Delta E^* = \alpha W_i$.

In this scheme W^* remains unaffected and the rate of reaction as determined by Q_1 should vary in a predictable way. There should be a decrease of Q_1 by $-\Delta Q_1 = \alpha W_f$ in the first instance and an increase $\Delta Q_1 = \alpha W_i$ in the second. Both cases would be covered by the relationship $\Delta Q_1 = -\alpha \Delta H$, which expresses a kind of revived Berthellot principle, connecting rates of reaction with heats of reaction (Fig. 2).

The conditions in which such a relationship can be postulated are clearly of a very special kind. They can be upset even for our chosen reaction—chosen for its particular simplicity—whenever there are present in the transition state additional bond assignments which do not appear either in the initial or the final state[4]. Suppose there is an oxygen atom present in ClR, as, for example, in $ClCH_2(CO)CH_3$. There is then the possibility that the Na + $ClCH_2(CO)CH_3$ transition complex will resonate with the alternative bond assignment $Na^+ + ClCH_2(C^{\cdot}–O^-)CH_3$. From this there will result an addition (W_1^*) to the resonance energy in the transition state and the activation energy will be reduced by an equal amount.

There is a further complication arising from the fact that in the free radical there is a lone electron which will tend to resonate in about the same way as the valence electron of sodium, causing, for example, in the radical $.CH_2(CO)CH_3$ the additional bond assignments $^+CH_2(\dot{C}–O^-)CH_3$ and $CH_2 = (C^+–\dot{O}^-)CH_3$. Hence there will be present also a certain amount of resonance energy (W_f) in the free radical, and the total depression of the activation energy will show the combined effect of W_1^* and W_f, so that $\Delta Q_1 = W_1^* + \alpha W_f$. Since we cannot calculate W_1^*, we can expect to ascertain this peculiar effect of the CO group (or of any other negative group having a similar function) only qualitatively by the existence of a ΔQ_1 that is distinctly larger than $-\alpha \Delta H$.

The experimental material which so far has been analysed in the sense of these ideas is collected in the accompanying table. A glance at the first column of figures shows that there is a distinct depression of the activation energy (as compared with $ClCH_3$) in a number of instances where an increased heat of reaction may be expected on account of resonance in the final state. Allyl-, benzyl- and acetonylchloride belong to this class. We also note that the two compounds, vinyl- and phenyl chloride, which react more slowly than methyl chloride, are both of the kind in which resonance would decrease the heat of reaction.

Radical (R)	Activation energy Na+Cl R (Q_1)	Substitution heat: RH+OH = ROH+H (Rossini[5])	First order constant of IR pyrolysis at 430° (k)	Activation energy of IR pyrolysis (Q_1')
vinyl	10·4		6	55
phenyl	10·4		14	54
methyl	10·0	16·0	14	54
ethyl	9·4	10·2	50	52
n-propyl	9·2	8·8	250	50
n-butyl	8·6	8·2	560	49
*iso*propyl	8·6		4000	46
t-butyl	7·8		9000	45
allyl	6·0		600000	39
acetyl	5·0		160	(51)
benzoyl	0		18000	44
acetonyl	2·0		9000	45
benzyl	2·9		23000	44

There is also a good deal of evidence favouring the assumption that the observed falling activation energies in the series methyl, ethyl, *n*-propyl, *n*-butyl, correspond to a parallel increase in the heat of reaction. In the second column of the table is a list of reaction heats, which show that the difference of the bond energies R–H and R–OH goes on decreasing all along the series. The only explanation for this effect seems to be the presence of a radical resonance of the type $CH_3 - CH_2^{\cdot} \longleftrightarrow H^{\cdot} \ldots CH_2 = CH_2$ which weakens both the R–H and the R–OH bond, but affects the latter to a much less extent[6,7]. Moreover, claims to have actually observed a fall in the bond energy of C–H by passing from CH_4 to C_2H_6 were quite recently made by D. P. Stevenson[8] and, independently, by Anderson, Kistiakovsky and Van Arstdalen[9], the values being given as $D(CH_3–H) = 101$ kcal. and $D(C_2H_5–H) = 96$ kcal. in the first and as $D(CH_3–H) = 102$ kcal. and $D(C_2H_5–H) = 98$ kcal. in the second instance.

Once a resonance of the type $CH_3 - CH_2^{\cdot} \longleftrightarrow H^{\cdot} \ldots CH_2 = CH_2$ is assumed to be effective, an even stronger effect of this kind must be taken to be present in secondary and tertiary radicals such as $(CH_3)_2CH^{\cdot}$ and $(CH_3)_3C^{\cdot}$. This would cause a marked fall in the heat of reaction in the series ethyl, *sec.*-propyl, *tert.*-butyl and make the observed fall in the activation energy in this series appear as a further qualitative corroboration of the above theory.

A further corroboration of at least an approximately quantitative kind can be based on observations of the pyrolysis of compounds in which chlorine is replaced by iodine. In a series of experiments made during 1938–40 and now in the course of publication, E. T. Butler and I observed very wide variations in the rates of pyrolysis of different iodides[12]. The observed rates extrapolated to a common temperature 430° C.—listed in the table—vary in a sense largely parallel to the rate of the sodium vapour reactions of the corresponding chlorides. The experimental conditions of the pyrolysis were such that the rate was likely to be governed primarily by the monomolecular dissociation of the C–I bond. If that is so, then $Q'_1 = (13 \log k)RT$ should correspond approximately to the energy of that bond. This assumption is supported by the fact that the Q'_1-values calculated for methyl iodide and ethyl iodide from this relationship closely correspond to the C–H bond energies mentioned above[10] and established quite independently after the preliminary publication[11] of our results. The table shows further a reasonable measure of agreement with such variations in bond-energy as may be expected to occur from considerations of resonance. On these grounds we felt justified in attempting a verification of the relationship $\Delta Q_1 = -\alpha \Delta H$ by setting $\Delta H = \Delta Q'_1$ (Fig. 3).

It is clear that for the compounds listed in the figure a marked parallelism exists between activation energy and the postulated variation of reaction heat. It is also clear that the proportionality factor α is—as the theory requires it to be—a fractional magnitude, somewhat less than one half. It so happens that the straight line in Fig. 3 drawn by the method of least squares defines a factor $\alpha = 0{\cdot}28$ which actually agrees closely with the value derived for α from Fig. 2; but this precise correspondence must be regarded as a mere coincidence.

Fig. 3 does not contain the three oxygen-containing compounds acetyl-, acetonyl- and benzoyl chloride, nor does it contain benzyl chloride. In all these cases the activation energies are much lower than the relationship $\Delta Q_1 = -\alpha \Delta H$ would lead one to expect, and the values fall altogether out of the picture. This is exactly what we predicted above for the oxygen-containing compounds, for which an extra resonance in the transition state was postulated. It would seem that the C_6H_5 group exercises a similar influence to oxygen, though in this case the mechanism is still obscure.

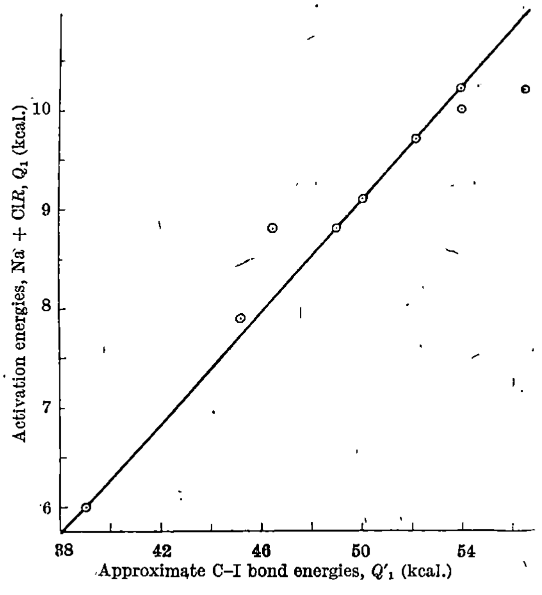

Fig. 3.

It seems reasonable to hope that when this kind of investigation can once more be resumed, further parallel observations on the rates of the sodium vapour reaction of halides and of the rates of their pyrolysis (compared also with the rates of some corresponding reactions in solution) may be found to disclose clearly the main factors which determine the effect of chemical substitution on reactivity. The theory—with all its present weaknesses—seems to have allowed us to recognize the type of reactions in which the simplest conditions are likely to prevail, as well as the factors that have to be considered in the first place when analysing the results.

---

[1] Systematic speculations on the mechanism of chemical reactions were first started by F. London (1928) and by H. Eyring and M. Polanyi (1931). The simplified theory of 'ionogenic reactions' used in the text was first suggested by Ogg and Polanyi (*Trans. Far. Soc.*, 31, 607; 1935) and later elaborated by M. G. Evans and Polanyi (*Trans. Far. Soc.*, 34, 11; 1938).

SOME EARLY CZECH CONTRIBUTIONS TO BOTANY

By DR. GERALD DRUCE

IN Bohemia the science of botany began, as elsewhere, through its applications in medicine and agriculture. A consideration of the uses of plants led to the first Czech writings on the subject before there was any idea of a study of plants for their own sake. Herbals, containing descriptions of local plants, began to appear in the fourteenth century and were more or less elaborately illustrated. Probably the earliest in Bohemia was the "Lekarszké Knizky" or "Erbarius", of Christian of Prachatice, who was a *Magister* of the University of Prague, where he taught between 1392 and 1435. It listed 156 plants, and this was first printed from the original manuscript in the sixteenth century[1].

Of more importance was the "Kniha lekarzská kteraz slowe Herbarz, aneb Zelinarz" of Jan Černý (1480–1530). It was first printed at Nuremberg in 1517, then at Prague in 1544 and 1554, and at Olomouc in 1554, and was illustrated with woodcuts and had considerable importance, as its many editions indicate. It was, in fact, more than a herbal since it contained accounts of minerals and inorganic substances then used in medicine, for Černý was primarily a medical man interested in plant products.

Other early Czech herbalists include P. A. Matthiolus, who also wrote a commentary on Dioscorides

(1554), and the medical man, Thaddaeus Hájek (1525–1600), who translated Matthiolus's Latin work into Czech and produced an original "Herbarz ginak Bilinarz" (Prague, 1562).

The first Czech to claim to be a botanist pure and simple was Adam Zalužanský, born at Mnichovohradiště in 1558, who died of the plague in 1613. He was the first writer to advocate a study of plants as a separate science. In his "Methodi Herbariæ" he wrote: "It is usual to connect medicine with botany, yet scientific treatment demands that we should consider them separately. For in every science the theory must be dissociated from practice and the two must be dealt with separately in their proper order before they can be united. Botany (which is, as it were, a special branch of physics) should form a unit by itself before it can be brought into connexion with other sciences." Zalužanský was a remarkable man. He graduated at Prague in 1581 and after some years of travel returned to lecture on natural philosophy. He was elected rector of the University in 1593 and attempted to re-organize the curriculum as well as introduce complete religious freedom and secularize the University. He wanted especially to advance and broaden the teaching of science. His work, "Rzad Apothekarzský" (1592), set forth the scope and aims of pharmacy and the duties of apothecaries towards the community. As a botanist he has been compared with Cæsalpino, and though his herbal was not in advance of contemporary publications as regards the number of specimens described, it was unique in giving a comprehensive survey of botany as a distinct subject. In his classification he began with fungi as the lowest (known) organisms, passing to mosses, then ferns, grasses, other flowering herbs, and concluding with trees. He endeavoured to pass from simpler to more complex types and evidently regarded lower cryptogams as primitive types. Considerable importance was attached to leaf appearance, and this led him to class umbellifers and even some of the composites with the ferns.

The contemporaries of Zalužanský included Jacob Hořčický (1575–1622), keeper of the gardens of Rudolf II and Jan Jesenský, or Jesenius (1566–1621), a Silesian Czech naturalist and medical man who became rector of the University of Prague and was among the anti-Hapsburg intellectuals executed in 1621. Hořčický, or Sinapius, was court apothecary and specialized in the cultivation of herbs which he distilled in steam (according to a method probably acquired from Černý's herbal) to yield aromatic "waters" which are credited with curing Rudolf from an acute attack of gout so that the emperor ennobled him with the title, *von Tepenec*.

Zalužanský died just before the disturbing times of the Thirty Years' War and its persecution of the Czech people. All progress in science was checked for a hundred years. Except for occasional references to botany and other sciences scattered through theological writings, no attempt was made to impart any scientific knowledge in the schools or at the University. One such reference is that of Marcus Marci in "Idearum operaticum idea" (1667), where an account is given of "metamorphosis" in plants. Importance out of all proportion to its scientific merit, therefore, is attached to the collection of plants made by the priest, J. F. Bečkovský (1658–1725). It contained about two hundred specimens, but Bečkovský was an amateur rather than a serious botanist and knew only the herbal of Matthiolus. He confused many different plants and frequently assigned wrong names to his specimens.

In 1662 the University of Prague received new statutes. One of these provided for five professors in the medical faculty, including one for botany. The curriculum was to include a study of medicinal plants, to be undertaken in the summer of the first year of study, and in the third and fourth years instruction was to be given in the preparation of plant medicines. Science, however, did not flourish, and in 1688 the faculty had only three professors and four unpaid assistants. What lectures there were in botany were given by the professor of anatomy and surgery. Between 1649 and 1740 thirteen lecturers in botany were appointed and not one made the subject his first interest. Two of them, J. J. V. Dobřenský (1632–97) and J. A. Scrinzi (1697–1773), are worthy of some consideration. Dobřenský was a medical man who had studied in Modena and Ferrara. He knew more chemistry than botany though he taught both and wrote about a dozen Latin works on natural science and medicine. Scrinzi was the first occupant of the chair of chemistry and physics at Prague. He practised medicine at Mladá Boleslav, about thirty miles north-east of Prague. It was Scrinzi who demonstrated the evacuated 'Magdeburg hemispheres' before Maria Theresa in 1754, using two teams of horses that failed to draw them apart.

In 1755 K. Sagner (1721–81) was lecturer in botany and printed for his students a work entitled "Institutiones Philosophicæ", which contained a general account of botany, including a carefully arranged section of plant physiology as then understood. He was one of those appointed as a result of the changes introduced during Maria Theresa's reign (1740–80) through the insistence of her physician, Gerhard van Swieten. The first professor of botany and materia medica was a Dr. Scotti, who planned a physic garden in 1752 and by which he is remembered. His successor was a Czech, Jan Bohadsch, or Bohač (1724–68), whose lectures had to cover the whole field of natural science. He made excursions all over Bohemia to collect material for a monograph, "Flora, fauna et historia lapidei Bohemiæ", which remained, however, in manuscript. After his death during an excursion in west Bohemia there was no professor in natural history until 1775, when his pupil, J. J. Zauschner (1737–99), was appointed. Zauschner made various contributions to the advancement of botany in Bohemia, including the re-discovery of *Gagea (Ornithogalum) bohemica*[2] mentioned by Černý, but afterwards overlooked. At this time it became possible to announce discoveries and to describe unusual plants and other scientific phenomena, since in 1770 there was formed a society for the advancement of science. It was at first styled the *Privatgesellschaft* (*Učená Společnost*, or 'learned society'), but in 1784 adopted the more expressive title of Royal Bohemian Scientific Society (Kralovská Česká Společnost Nauk). Among the original members were Bohač, Zauschner and another botanist, Jan Mayer, and it had several patrons among the nobility. In 1774 the Society offered prizes for work in science, and these were awarded to K. Sandberg of Brno and A. Voigt of Vienna. Sandberg's essay directed attention to the absence of an adequate Flora of Bohemia, and this prompted botanical excursions to various parts of the country, particularly to the Giant's Mountains. The Society published the results of these expeditions in a series of essays which gave an impetus to the study of plant life. Notable among them were the observations of Thaddæus Haenke (1761–1817). His detailed work on the flora of north Bohemia brought him into prominence and led to his famous expedition to South America under the patronage of Count Sternberg. The masses of material he dispatched to Prague were later the subject of a handsome work in two volumes known as the "Reliqueæ Haenkeanæ", in the production of which the best Bohemian botanists collaborated.

The first attempt at a complete Flora of the country was that of F. W. Schmidt ("Flora Boemica"), which appeared in 1793–94. It was, however, uncritical and included plants that the author guessed would be found in naturally rich areas like the Giant's Mountains and the Bohemian Forest. A second attempt was made by Prof. Jan Novodvorský (1773–1810), but his manuscript was burnt just before he died. A third work, by J. E. Pohl (1782–1834), was also fated to remain unfinished, though two parts of his "Tentamen Flora Boemiæ" did appear in 1817. Pohl's flora was based on his own observations and on those of others which could be verified by visits to the localities where the plants grew.

Far superior was the "Flora Čechica" of the brothers J. S. and K. B. Presl. It had been completed in 1812, but was not printed until 1819. The preface was in Latin and was followed by a section in Czech, *Napomenutí* (reminders), in which the authors explained how they revived Czech botanical terms and also introduced new ones where needed by adapting Polish or Russian expressions to bring the subject into line with the Linnean system, which they followed in compiling the Flora. J. S. Presl, who did so much to advance the study of science among the Czech people, whereas his brother was more occupied in original investigations, particularly in connexion with the study of ferns, wrote a general text-book of botany ("Rostlinář", 1822), which included introductory biology, plant chemistry, besides anatomy, plant physiology and what would now be styled ecology. The illustrations were remarkably faithful, and some copies were hand-painted by his sister. It served as the basis for later Czech botanical treatises, and most of the terms used for flowering plants are still applied to-day, but those relating to cryptogams have largely disappeared or undergone alteration.

In addition J. S. Presl wrote an elementary botany and also an advanced work, "Všeobecný Rostlinopis" (general botany) in two volumes of more than two thousand pages. It appeared in 1846, and four thousand copies were circulated, a remarkable tribute to the interest in botany shown by a small nation in the middle of last century. K. B. Presl's work reached a more international public since he wrote mostly in Latin. Fourteen of his papers are listed in the Royal Society's catalogue of scientific papers. His books include a classic on ferns, "Testamen Pterodographiæ" (1836), with beautifully executed plates, many of the species being described for the first time. It classified 117 genera, and a supplement in 1845 brought the total to 132. This was his greatest work, though he also wrote a monograph on lobelias[3].

Several nobles, who were landowners in Bohemia, also encouraged the development of science. Thus, Count Malabaila Canal (1745–1826) was interested in applied science, cultivated a garden of economic plants and founded a lectureship in applied botany, the last lecturer being K. B. Presl. He encouraged the growing of sugar beet and established the first Czech factory for its extraction. He also improved fruit cultivation by introducing better grafting methods. Count Berchtold encouraged the cultivation of more potatoes, patronized contemporary botanists, and was a generous supporter of the National Museum. He wrote a standard work on the potato, and also a book on economic plants[4]. But the greatest botanist among the Bohemian nobles was Count Kaspar Sternberg (1761–1838), who not only supported contemporary Czech men of science but also was himself an investigator and author of considerable merit[5]. Most of his seventy-four works were in German, though he refers to Czech as "our tongue" and he translated some Czech mining notes into German in his paleobotanical treatise, "Flora der Vorwelt". He was instrumental in founding the Bohemian National Museum in 1818, became its first president, and gave it his herbarium of 9,000 specimens, to which he added purchases from abroad and the collections sent by Czech botanists from overseas. Sternberg also appointed Palacký, the historian, to be editor of the Museum's quarterly journal, and this has since been a powerful propagator of science among the Czech nation up to the present time. His last public function was to preside over a congress of medical men and naturalists at Prague, and he took great pride in announcing the recent discoveries of Purkyně, the Presls and others, to show that the Czech nation was making its contribution to the advancement of science whatever might be the truth of Liebig's recent assertions concerning the low level of science in Austria[6].

---

[1] The works mentioned in this article were consulted at libraries of the Czech National Museum, the Charles University and other institutes in Prague, and at Brno and Litomyšl in Czechoslovakia. Some works were read at the British Museum and at the library of the London School of Slavonic Studies.

[2] Much information relating to the development of botany in Czechoslovakia is contained in "Vývoj české Přírodovědy" (Development of Czech Natural Sciences) edited by the late Dr. L. Viniklář, 1932).

[3] K. B. Presl's name is attached to seven species of ferns native to Britain according to G. C. Druce's "Pocket Handbook to British Plants". Riley's "Catalogue of Ferns" (London, 1841) contained "additions by C. B. Presl".

WAR-TIME NURSERY SCHOOLS

By Mrs. F. A. OGDEN

SCHOOL nurseries are not by any means new ventures even in Great Britain, but war-time conditions are responsible for their immediate expansion and improvement. Nursery schools for the care of the 2–5 year old children were established by local authorities in many parts of England during the 1914–18 period and afterwards, but in very few cases was there accommodation adequate to the growing needs. Schools were started in an experimental sort of way, and the permissive attitude of the Board of Education seemed to encourage the lull in progress. It would have been fortunate for the country if every local education authority had been in control of sufficient nursery schools to cope with all the 2–5 year old children in 1939. When war broke out and the call for women in industry became accentuated, so the need for proper accommodation for their young families made itself felt, and war-time nurseries were speedily developed. In some centres new nursery schools were prepared or completed. In many, nursery classes were established in the junior schools and these brought a new low age-level of infant classes where, in difficult circumstances, children under two years of age were admitted. In more isolated places day nurseries were set up by voluntary bodies and these experiments certainly played a part in urging accommodation to meet the new needs. To release young mothers for essential war production, residential nurseries for children of less than two years of age became necessary, and maternity and child welfare committees of local authorities acting under the Ministry of Health made rapid progress in providing suitable accommodation. Grants to local authorities for establishment and maintenance by the Government were very generous, and the needs of the population of working mothers in most industrial areas was in some measure supplied. In the years 1937 and 1938 immediately preceding the War there were 107 nursery schools in Great Britain, registering an average attendance of 8,274 children less than five years of age. Thus it will be seen that a very small proportion of the population was then accommodated. In addition to further schools of this type in 1942, there were more than 1,000 day nurseries, 400 residential nurseries and 500 more in course of preparation. Nurseries of to-day can be grouped under the following heads:

(1) Nursery schools (under the authority of the local education committee and the Board of Education), day only;

(2) War-time nursery classes (under the authority of the local education committee and the Board of Education), day only;

(3) Residential war nurseries (under the authority of the Maternity and Child Welfare Committee and Ministry of Health), 24 hours or 6 days.

(4) Voluntary nurseries controlled by other voluntary organizations, such as the Women's Voluntary Service, Canadian Red Cross, British Red Cross, Anglo-American War Relief Fund, etc.

In day-nursery classes difficulties arising from war conditions, such as hours of work of parents on night shifts, etc., had to be met, and it became necessary to revise the hours of attendance of teaching staff in the junior schools affected. It would be impossible to pay too high a tribute to the young teachers who took voluntary duty at 6 a.m. or stayed until 8 p.m. to meet the convenience of war working mothers. Difficulties in providing equipment were met by the combined efforts of amateur craftsmen in A.R.P. posts, schoolboys in woodworking classes, W.V.S. sewing and knitting parties—and bright toys soon changed the school atmosphere and produced a delightful nursery air. Stencilled friezes of wonderful design in gay colours shut out the heavy tones of a dreary outside world; inviting rest hammocks with cosy rugs appeared; accommodation for personal hygiene was provided or multiplied; miniature towels, toothbrushes and bright pinafores made their appearance; in other rooms dainty tables and small chairs with crockery and gaily coloured cloths were installed.

The ideal nursery school is a place of great delight. The tiny children arrive in charge of mother, father or elder one of the family at 6 a.m. or 8 a.m. A young teacher with the right feminine instincts normally takes over. With quick observation she registers tired or rested, sick or well, washed or unwashed; outdoor clothes are divested, hands and face washed, personal attention given if needed, and the child is soon absorbed in the inviting atmosphere, losing his self-interest and forgetting his little worries. Later, tables are prepared for breakfast and four little people take their chair to a table, where after a simple grace they are soon enjoying their first meal of the day—a well-balanced, healthful breakfast.

Self-education is a great feature of the nursery training to-day. Careful direction is given, but the temptation to which mothers so often yield to 'do for' and to 'show how' is advisedly resisted. It is not unusual to see a child of three years working with a small hammer and a few nails and, without any outside help, producing a simple toy roughly put together but with a clear indication of achievement which is easily recognized; it is to the child-mind a real boat or ship complete with mast, or a bomber plane fitted with bomb racks (this is a record of actual observation). Perfection in execution is a far step, but the self-conceived idea, the attempted expression and satisfaction in completion are valuable apperceptive links for the child and valuable guide lines for the teacher. Primitive dolls in cradles or beds, gardens and hen coops indicate other lines of interest, while on one occasion a child revealed that its chief delight was in producing coffins with tiny bodies rolled out in plasticine lying therein. When the play period is ended, the morning milk, cod liver oil or fruit juice is given, according to nurse's directions, to each child, and a period of restful attention to teacher's talk provides a physical relaxation as a counterpart to the engagement of the mental faculties. Time for lunch soon arrives and training in personal hygiene precedes the meal. The older children of four and five years are very quickly trained to help in serving and assisting the younger members of the community, showing good examples in table manners to the less advanced. The lunch is balanced on dietetic principles by the medical officer and his staff, cooked by a trained woman, and is designed to give all the nourishment required at the proper age. After the lunch, while the children have a period of free play, with toys indoors, or in the sunshine out of doors, the rest hammocks are disposed on the floor and tired little heads and hands are soon resting on them. Even here the teacher's watchful eye must be on the alert. Restlessness must be carefully noted and investigations made which may result in the temporary attention of the teacher or in the calling of a nurse or even a doctor. Much can be learned of a child's temperament and condition by a careful observation of its resting period.

Observation of the child's play interest and activities is a most valuable index to the understanding teacher of his moral and mental tendencies and his growing character. Stimulation or discouragement at the right moment may help to attain the proper balance which results in a normal social attitude.

The importance of early training in regular personal habits cannot be over-estimated. The instincts of the primitive peoples are sometimes reflected in child behaviour. The wolfing of food at irregular times, attacks on weaker children which seem sometimes to have no object but subjugation, the acquisition of coveted toys by force, the destructive craze, or the satisfaction resulting from obvious discomfort in others, are examples of under-developed and uneducated reaction. Careful training in proper behaviour and regular habits with a view to the comfort and happiness of the community is an aim of nursery school life. Self-control is induced by insisting on the proper time for personal hygiene. This may have far-reaching consequences and provide a sound basis for character formation which will react to the individual and communal benefit in later years. From the point of view of physical health, conditions in war-time nurseries are more propitious to sound development than those in 90 per cent of the homes from which the children are drawn. The balanced diet; the opportunity for fresh air and play; regulated sleep; the use of educational toys; the advantage of communal interests and choice of companionship; the opportunity for free expression in the choice of toys are all advantages which could not be supplied in the great majority of the homes from which the children have come.

The teacher who is suitable for nursery school work has special qualifications natural to her character. With a good educational background she develops the capacity to make herself understood by small children. Her voice is gentle and clear. If she has imagination she can make the nursery stories live so that they will remain as an influence with the young minds long after school days. The ability to draw, with a good sense of colour, to play simple nursery songs and to sing lullabies is a very desirable addition to her qualifications. Above all, she should be healthy with a developing maternal instinct of her own, finding its early expression in a communal way and giving sympathetic understanding and love to the children under her care. In the last two years there has been great competition to enter colleges for nursery school work, and this should have made it possible for the most suitable young people to be selected. It is therefore a well-founded hope that future years will provide a sufficient staff of the right quality for the nursery schools which we hope to see in abundance in a post-war period. At the moment the teaching staff of war-time nurseries is deplorably inadequate. A considerable proportion of it consists of young girls leaving school at the age of fourteen who with a short course of six weeks training have loyally undertaken the responsibility. A large proportion also consists of older mothers whose families are grown up and who may have had little contact with young life in the last twenty-five years. Nevertheless they too have loyally placed their service at the call of the country's need, and the valuable maternal instinct which has been the foundation of a short course of training lasting 4–6 weeks has of necessity had to be their only training for this very responsible and important work.

Records of progress show that physically and mentally the children in these schools have received great benefit, and the contribution to the stamina and resource of the nation cannot be properly assessed at this juncture. It may be, however, that out of this war-time experience will grow a permanent and complete scheme for the proper care of young life.

OBITUARIES

Prof. F. D. Adams, F.R.S.

FRANK DAWSON ADAMS, emeritus Logan professor of geology and vice-principal of McGill University, Montreal, died on December 27 at the age of eighty-three. He was one of the great pioneers in the study of the Precambrian rocks of Canada and in the field of experimental geology. Born in Montreal on September 17, 1859, Adams was educated at McGill University, where he came under the influence of Sir William Dawson, his great predecessor in the Logan chair. After a year of postgraduate study at Yale, he was appointed an assistant on the Geological Survey of Canada: in this service he continued until 1889, when he resigned to become lecturer in geology at McGill University, succeeding to the chair four years later.

Adams's first field investigations were devoted to a study of the character and relations of the large anorthosite bodies lying near the border of the Canadian Shield, north of the St. Lawrence River, within and close to Logan's original Laurentian area. This group of rocks, in places exhibiting a distinct foliation, was supposed by Logan to form a stratified series—his Upper Laurentian—distinct from, and reposing on the Grenville Series. Adams at this time was well equipped for his task—he was a skilled petrographer versed in the new methods of the science, for he had already studied under Rosenbusch—and the detailed mapping he began in 1883 soon brought results of the first importance. He conclusively demonstrated the igneous nature of the partly foliated anorthosites, revealed the aqueous origin of an important group of highly metamorphic garnet gneisses within the Grenville Series and was thus led to a fundamental revision of the classification of the Precambrian in the St. Lawrence area. Some of these results were published as a dissertation at Heidelberg, where he had continued his researches under Rosenbusch during several summer semesters.

Meantime, the epoch-making investigations of A. C. Lawson on the Laurentian succession in the Lake Superior region 800 miles westward had been published, and led Adams, on the completion of his researches in Quebec, to a detailed survey of a large area of the Grenville Series in Eastern Ontario in order to provide a satisfactory knowledge of the Precambrian succession in Eastern Canada. The region selected—the Haliburton-Bancroft area—was geologically almost a *terra incognita*, of which no topographic survey had been made. The field work, in which he was later joined by A. E. Barlow, occupied eight years, the results being published in a memoir in 1910.

These investigations form a classic study on the Canadian Shield and placed Adams in the front rank of petrologists. The phases of metamorphism and varied constitution of the underlying Grenville Series and the character and relations of the succeeding Laurentian granite 'batholiths' were brilliantly demonstrated, while the beautiful maps which accompanied the memoir have furnished the type material for all later discussions on concordant intrusives in folded sediments. Among the more striking petrographic results was the discovery of great bodies of nepheline syenite about the borders of the Laurentian granites. These alkali rocks presented many remarkable variations in composition, and some varieties, being rich in corundum, were afterwards made the basis of an extensive industry for the exploitation of this mineral.

Adams's ripe experience and acknowledged authority in the field of Precambrian research led to his appointment to several international committees to investigate critical localities and to report on the correlation and nomenclature to be adopted for the Precambrian areas on both sides of the Canadian boundary.

The second great field of endeavour in Adams's career was his study of the experimental behaviour of rocks under differential stress. His keen interest in this department of research was engaged by his long and close observation of the foliated and gneissic rocks of the terrains he had mapped and by the realization that light on this subject might be revealed by experiment in which the factors of pressure, temperature and solution were separated, and the part played by each investigated, first independently, and then in combination. In this work he had the great advantage of collaboration with his engineering colleagues at McGill, first of Nicolson, later of Coker, while his financial resources were supplemented by a grant from the Carnegie Institution. Their results are set down in a remarkable series of publications dealing with the experimental flow of rocks (1901), the elastic constants of rocks (1906), the flow of marble (1910) and an experimental investigation on the depth of the zone of flow in the earth's crust (1912, 1917).

Formerly, almost the only quantitative data on the mechanical behaviour of rocks had been obtained by crushing cubes of rock in a testing machine according to the ordinary rules of engineering practice. Adams's experiments clearly demonstrated that rocks change their character when a confining pressure is applied so that they are no longer brittle but behave plastically. He was able to show that the structures presented by the deformed rocks matched some of those seen among crystalline schists, that the plastic flow of marble in his experiments was associated with gliding or twinning of calcite, unaccompanied, even at the elevated temperatures used or in the presence of water, by re-crystallization, and that in order to develop flow within the crust a rock must be subjected to differential stress which is much, often many times, greater than that sufficient to crush it under ordinary conditions obtaining at the surface.

These experiments had a direct bearing on various problems presented in geophysics—among them the movement of nappes and isostasy—and they have been the first to supply the much needed quantitative data for the study of these and related problems. As such they have formed the pioneer researches in this field of experimental geology, and it is only within recent years that investigation on these lines has been renewed under more closely controlled experimental conditions which advance in technique has permitted.

After his retirement from the Logan chair at McGill, Adams's activities continued unabated. He visited the Far East and spent several field seasons in Burma, Malaya and Ceylon. The most important of his publications during this period was his "Geology of Ceylon" (1929), which presented the first geological map of the island and the first attempt at deciphering its larger structures.

Adams's keen interest in the history of his own chosen field of geology was evinced in many of his early writings. Through the years by diligent search he had gradually acquired a great collection of rare historical texts, and their study served greatly to enrich the scholarly memoir on the "Birth and Development of the Geological Sciences" (1938) which formed the final product of his labours.

During a long and distinguished career, Adams received many honours both in Britain and America. His frequent visits to Great Britain had brought him into close contact with the leading British geologists, and he was a well-known figure at scientific congresses. He was elected a fellow of the Royal Society in 1907 and he was a foreign associate of the U.S. National Academy of Sciences; he served as president of the Geological Society of America (1918), and as the outstanding Canadian geologist of the time was chosen as president of the International Geological Congress which met in Canada in 1913.

C. E. Tilley.

Mr. F. W. Harbord, C.B.E.

Mr. Frank William Harbord, who died on December 27, at the age of eighty-two, after a long and active career as a metallurgist, was born in Norwich and studied at the Royal School of Mines. After holding posts in iron and steel works in Staffordshire he became consulting metallurgist to the Indian Government, and from 1892 until 1905 he was at the Royal Indian Engineering College at Coopers Hill. In 1905 he took up private consulting practice in London, and the firm of Riley and Harbord (later Riley, Harbord and Law) has always enjoyed a high reputation in the metallurgical world. Although greatly hampered in later years by failing eyesight, he retained his position as senior partner until his death.

Harbord published very few original papers, but he contributed regularly and usefully to the discussions before the Iron and Steel Institute, and his text-book on the "Metallurgy of Steel", in which Mr. John Hall collaborated on the engineering side, reached a seventh edition and long retained its position as the standard English authority on the subject. In his earlier career he published papers on the removal of non-metallic elements from steel in the basic open-hearth process, on nitrogen and arsenic in steel, and on the relations between the properties of steel and its process of manufacture. In 1937 he reviewed very fully the history of the basic Bessemer process, drawing largely on his knowledge of the men connected with its development. The problem of the efficiency of steel works was discussed by him on several occasions.

He was closely associated as a consultant with the development of many new inventions, and in 1903, at the request of the Canadian Government, he reported on the position of electric smelting processes. During the War of 1914–18 he rendered valuable services as honorary metallurgist to the Ministry of Munitions, and at its end was awarded the C.B.E. He was also an officer of the French Legion of Honour.

Harbord took an active interest over many years in the work of the Iron and Steel Institute, being a regular attendant at its Council and committee meetings. He received the Bessemer Medal of the Institute in 1916. His kindly character made him a very popular member.

C. H. Desch.

We regret to announce the following deaths:

Dr. George Crile, director of research at the Cleveland Clinic Hospital, of which he was one of the founders, and an honorary fellow of the Royal College of Surgeons, who was known for his work on surgical shock, on January 6, aged seventy-eight.

Sir Arbuthnot Lane, Bt., C.B., the well-known surgeon, on January 16, aged eighty-six.

Sir Henry Maybury, G.B.E., K.C.M.G., C.B., president in 1933 of the Institution of Civil Engineers, on January 7, aged seventy-eight years.

NEWS and VIEWS

Lister Institute of Preventive Medicine

Sir John Ledingham, C.M.G., F.R.S.

Sir John Ledingham, who will retire from the directorship of the Lister Institute of Preventive Medicine at the end of next March, has served the Institute for thirty-seven years, during which he has come to occupy a leading place in bacteriological studies. His wide and detailed knowledge of the literature of bacteriology and immunity and his personal participation and intimate association with many aspects of related research led to his large share in the initiation and production of the Medical Research Council's "System of Bacteriology" in nine volumes (1928–31), which aimed at presenting the British view of the subject. By installing at the Lister Institute the M.R.C. National Collection of Type Cultures, which before the War distributed 5,000–6,000 cultures to all parts of the world annually, and by acting as its director, he greatly furthered the study of bacteriology. In 1907 he began an extensive investigation of carriers of *B. typhosus*, and work on carriers of diphtheria and dysentery bacilli and of the meningococcus was also undertaken in the Department. As the result of detailed studies from 1924 onwards of the skin reaction to intra-dermal inoculation of vaccinia virus, Sir John showed that the elementary bodies described by Paschen in 1906, but afterwards rejected by most bacteriologists, were indeed the pathogenic virus, and were derived from the intracellular inclusions (Guarnieri bodies). Sir John was able to concentrate and purify the virus by centrifuging and to obtain an agglutinating serum for the elementary bodies. In his Harben Lectures (1925), he summarized his work and the then known facts concerning natural immunity, the carrier problem and the variola group of diseases.

In 1932, Sir John Ledingham turned his attention to the causal agent of pleuro-pneumonia of cattle and pointed out that this so-called virus was quite unlike the true viruses, such as those of vaccinia and foot-and-mouth disease, etc. Although filterable in certain stages, its growth on culture media and its varied forms showed that it belonged to a special group, of which the microbe of Agalactia of sheep and the symbiont occurring in cultures of *Streptobacillus moniliformis* were members, as well as certain pathogens from the lungs of rats and some saprophytic forms found in sewage. During Sir John's directorship, the Serum Department at Elstree and the Biochemical Department in co-operation have devoted much time to the selection and purification of bacteriological antigens for use as prophylactic vaccines and for the immunization of horses, and considerable improvements have resulted, especially in dealing with sporing anaerobes, the meningococcus and *B. typhosus*.

In 1935 a Department of Biophysics was opened at Chelsea and a high-speed centrifuge reaching 60,000 r.p.m., an equilibrium centrifuge and an electrophoresis apparatus, all designed by Prof. The Svedberg, were equipped by the generosity of the Rockefeller Foundation. By these means the constituent factors of sera and other mixtures of proteins have been separated and examined and the elementary bodies of several viruses concentrated and purified. Other physical problems connected with the freezing and drying of these substances have also been attacked. Among other lines of research in which Sir John and the bacteriological staff have been specially interested have been phagocytosis, tularæmia, the diffusion factor in wounds, and the connexion between purpura and blood platelets. The Departments of Protozoology, Endocrinology, Biochemistry and Nutrition have continued research work with great activity. The last has been particularly occupied with the standards of vitamins and the fundamentals of war-time diets.

Dr. A. N. Drury, F.R.S.

Dr. Alan Nigel Drury, who is to succeed Sir John Ledingham as director of the Lister Institute of Preventive Medicine on April 1, is a distinguished research worker in the field of experimental pathology. In its widest sense that term would, of course, include all the experimental studies of the mechanisms of infection and immunity which have attracted so large a part of the attention of research workers in pathology. Such studies must always provide an important part of the experimental foundations of preventive medicine, and many of the investigations which Sir John Ledingham has made and directed have been of this nature. There is another very important section of experimental pathology which focuses attention on the abnormalities of bodily function produced by diseases, whether these are due to infections or to other causes. Dr. Drury is one of the relatively few in Great Britain who have made the advancement of knowledge in this field of morbid physiology the chief object of their activities in research; and he has used to that end his opportunities of research in the clinic as well as in the laboratory.

Dr. Drury had begun research work at Cambridge, as George Henry Lewes student, in 1914. At the outbreak of war he left for St. Thomas's Hospital to complete his medical course, and having qualified, worked with the R.A.M.C. in India, becoming D.A.D.M.S. (Sanitary) on the Headquarters Staff. After the War he resumed, under the Medical Research Council, an association with Sir Thomas Lewis, begun early in the War, and worked with him from 1921 until 1927 on the action of the heart in health and disease, being particularly concerned with the mechanism of fibrillation and flutter of the auricles. After a temporary spell of ill-health he returned to Cambridge, becoming Huddersfield lecturer in special pathology, and remaining a member of the Medical Research Council research staff. From 1928 onwards, and until the outbreak of the present War, he was again called into organization—this time of war researches for the Medical Research Council. He was engaged in a series of important researches, largely concerned with abnormal functions of the heart and circulation. With Dr. L. J. Harris he discovered the bradycardia produced by defect of vitamin B_1 (aneurin), and with A. Szent-Györgyi he identified a hitherto unrecognized series of circulatory depressants in adenylic acid and related derivatives. Other researches led to the probable identification of a surface-active brain constituent which combines with tetanus toxin, and demonstrated the cardiac hypertrophy resulting from the formation of an arterio-venous anastomosis. Like his distinguished predecessors at the Lister Institute, Dr. Drury may be trusted to encourage and promote researches in the general field of preventive medicine, widely beyond the range of his own direct activities as an investigator.

Colonial Products Research Council

THE Colonial Office has appointed a Colonial Products Research Council, under the chairmanship of Lord Hankey. Unlike the Colonial Research Committee under Lord Hailey, the Council will be an executive body. It will consider what Colonial raw materials may be made of value for the manufacture of intermediate and other products required by industry, and it will initiate and supervise researches, both pure and applied, on such products, and generally consider how by the application of research greater use can be made of them. In framing its programme the Council will have as its principal objective the promotion of the welfare and prosperity of Colonial peoples, and will endeavour also to increase the Colonial contribution to the welfare and prosperity of the British Empire and of the world as a whole. In carrying out its programme, the Council will co-operate with existing institutes, such as the Department of Scientific and Industrial Research, the Medical Research Council, and the Agricultural Research Council, to the greatest possible extent, and will 'farm out' work to these and other bodies by arrangement; it will set up facilities of its own only for work which cannot be done by other means. So long as the war continues, the investigations which the Council will be able to undertake will necessarily be limited.

The Council is composed as follows: Mr. Eric Barnard, director of food investigation, Department of Scientific and Industrial Research; Capt. G. L. M. Clauson, assistant Under-Secretary of State, Colonial Office; Mr. Aneurin Davies; Dr. J. J. Fox, Government chemist; Prof. W. N. Haworth, professor of chemistry, University of Birmingham; Sir Harry Lindsay, director of the Imperial Institute; Sir Edward Mellanby, secretary, Medical Research Council; Sir Robert Robinson, Waynflete professor of chemistry, University of Oxford; Mr. G. W. Thomson, president, National Federation of Professional Workers; and Dr. W. W. C. Topley, secretary, Agricultural Research Council. Prof. J. L. Simonsen, lately of the University College of North Wales, has been appointed director of research. Certain members of the Council are also members of the Colonial Research Committee, and the Council will work in close touch with that body. It will be financed out of the provision for research in the Colonial Development and Welfare Act.

A Photographic Record of the Linnean Collections

THE value of the Linnean collections of animals and plants and of the associated books and manuscripts needs no emphasis. They must always remain of supreme importance to systematists, and the Linnean Society of London has very rightly regarded them as its own special charge. In April 1939 the collections were moved for safety to Woburn Abbey in Bedfordshire, and with the advent of bombing raids in 1940 the Linnean Society, through its Council, took steps for preserving a photographic record of the collections. A generous grant of about £2,000 was made to the Society by the Carnegie Corporation of America for this purpose and the work took active shape in the latter half of 1941. In order to facilitate the work the collections were removed in July of that year to the Zoological Museum at Tring, formerly the property of Lord Rothschild and now a department of the British Museum (Natural History). It was decided to adopt photographs on 35-mm. microfilm and, by this means, it was estimated that it would be possible to make a complete record of all the specimens, books and manuscripts in the course of about nine months. In addition, this would allow of a copy of the finished film being sent to the United States and possibly others elsewhere. As an indication of the extent of the task it may be pointed out that the estimated number of exposures in the case of the plants was 14,000, for the insects 5,000, for the shells 2,000, for the fishes 158, and for the books and manuscripts 30,000—making altogether more than 60,000 exposures. Good progress has been made, and it is probable that the whole of the work will be completed well within the estimated period. The details of the steps taken and how the various difficulties were encountered, together with the services rendered by various specialists, are recounted in an article on the subject by J. R. Norman in the *Proceedings of the Linnean Society* for 1941–42 (Part 1, pp. 49–57).

Investigations in Afghanistan

MR. K. DE B. CODRINGTON has recently returned from Afghanistan. He joined Josef Hackin, director of the French Archæological Mission, in the spring of 1940 and was present during his last season's work at Begram, the site north of Kabul which has produced such remarkable finds. M. Hackin left Kabul in the autumn of 1940 to join General de Gaulle's staff in London, and later lost his life at sea. Mr. Codrington interested himself in the Afghan Government's recent adoption of Pushto as the national language, and wrote an introductory grammar of Kandahari Pushto in collaboration with Colonel Muhammad Yaqub Khan. He speaks warmly of the Afghan Government's interest in archæology and history, and of the work of the staff of the Kabul Museum and the Kabul Literary Society, who are engaged upon a national history. Through the kindness of H.R.H. Sardar Naim Khan, the Minister of Education, and of H.R.H. Shah Mahmud, the Minister of National Defence, Mr. Codrington was able to make collections of flowering plants and varieties of wheat. He also contributed specimens of fishes to the Zoological Survey of India. Certain specimens of Afghan wheat are already being grown at Cambridge, and it is hoped to carry this work further, with the assistance of the Afghan authorities.

Vitamin Production in the U.S.S.R.

AT a Conference of Biochemists held in Moscow last November, attention was directed to the possibilities of utilizing the extensive walnut forests of Kazakhstan as an almost inexhaustible source of vitamin C. The unripe walnut contains an unusual quantity of ascorbic acid, and vitamin C is already being manufactured from it on a commercial scale. It is hoped that the systematic exploitation of the walnut forests for vitamin C production will be fully organized this year. Many hospitals in northern districts successfully use an infusion of pine needles as a means of supplying vitamin C. Other measures adopted since the War for increasing supplies of vitamins include the production of yeast (as well as protein) from food waste, the manufacture of vitamin B_6 from tobacco waste, and the utilization of certain freshwater fish as sources of vitamin D.

The Bed-Bug

ECONOMIC Series No. 5 of the British Museum (Natural History) is an illustrated brochure entitled "The Bed-bug: its Habits and Life-History and how to deal with it" (5th edition, 1942), by A. W. McKenny Hughes and C. G. Johnson. This insect, at the present time, is very prevalent in the larger cities wherein many areas are heavily infested. Large-scale evacuation of the population has resulted in the creature becoming established in wide areas previously uninfested. After the War it is likely that further redistribution of large numbers of people will again be necessary. Many complaints have come to hand about public shelters and similar places where people congregate during air-raids being infested. It is obtainable, price 6*d*., from the Museum or through a bookseller.

Some Problems in Transmission-Line Design

IN a paper with this title read in London on December 9 before the Institution of Electrical Engineers, Mr. A. Burke gives particulars of some of the serious damage caused by snowstorms to electrical transmission lines in Ireland, and of consequent departures from conventional design. The factors governing the examination of breakdown data are analysed critically and the data and conclusions for particular cases are stated briefly. Loadings are compared with those specified by the British Regulations for Overhead Lines, and the effectiveness of the universal method of controlling the factor of safety of conductors is challenged. The superiority of a horizontal over a triangular arrangement of conductors is viewed from a new angle and the reasons for adopting a horizontal arrangement on wood poles for 260 miles of 110 kV. line are given. Various problems in connexion with the design of this line are set out, costs are given and the conclusion is drawn that it is much more economical than a line carried on lattice steel towers.

Journal of the Society of Glass Technology

THE general adoption some years ago of the glass bottle for the delivery of milk to the household brought about a wide realization of the importance of glass in everyday life. A war-time shortage of metal has led to many replacements of metal-can by bottle. There is therefore much of general interest scattered through each number of the *Journal of the Society of Glass Technology*. The latest issue, vol. 26, No. 116, includes a fully illustrated paper on "Cords, Surface Condition and Quality of Glassware", as well as more than sixty pages of abstracts. The *Journal* is issued bi-monthly from the University of Sheffield, Northumberland Road, Sheffield, 10.

Recent Earthquakes

THE United States Coast and Geodetic Survey, in co-operation with Science Service and the Jesuit Seismological Association, has determined the epicentres of two recent earthquakes. The first was on November 10 at 11h. 41·3m. U.T. and the provisional epicentre was latitude 35° E., longitude 46·5° S. This is in the bed of the ocean somewhat to the west of Prince Edward Island to the south of Africa. The second earthquake was on November 12 at 4h. 55·4m. U.T. and its provisional epicentre at latitude 16·8° N., longitude 94·2° W. This is in the high country to the east of Chimalapa in the Isthmus of Tehuantepec in Central America.

Comet Whipple

THIS comet is now a naked-eye object and has been observed in various parts of Great Britain. A new orbit has been computed by Dr. M. Davidson from observations extending over a much longer period than those which were used for the preliminary orbit given in NATURE of January 9, p. 51, and is more accurate than the earlier orbit. The comet will probably remain a naked-eye object for some time and will continue to move northwards until February 25, after which its declination will slowly decrease.

Orbit

Announcements

PROF. JOHN ALFRED RYLE, regius professor of physic in the University of Cambridge, and physician extraordinary to the King, has been elected professor of social medicine in the University of Oxford.

THE Committee of the Athenæum has elected the following, under the provisions of Rule II of the Club, which empowers the annual election by the committee of a certain number of persons of distinguished eminence in science, literature, or the arts, or for their public services: Prof. Emile Cammaerts, professor of Belgian studies and institutions in the University of London; Admiral Sir Andrew Cunningham; Prof. W. N. Haworth, professor of chemistry in the University of Birmingham.

THE People's Commissar for Education in the U.S.S.R. has instituted fifteen valuable Newton scholarships for Soviet university students. They are to be awarded to young men and women specializing in physics, mathematics, mechanics and astronomy. The Universities of Leningrad and Moscow will receive three scholarships each. Other Newton celebrations include exhibitions of portraits and books in English, Russian and other languages on Newton at the University of Moscow and the Scientists' Club.

A WEEK-END course on February 27 and 28 on factory medical services and industrial diseases for medical practitioners has been arranged at the London School of Hygiene and Tropical Medicine. The course will be opened by Sir Wilfred Garrett, chief inspector of factories, at 2 p.m. on February 27. The subjects of succeeding lectures are: industrial diseases of the lungs; skin lesions arising from coal distillation; the investigation of toxic hazards; a method of assessment of physical requirements for processes with reference to routine medical examinations; industrial fracture; and recent work on antiseptics. Applications to attend, with a fee of one guinea, must reach the Secretary, London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1, not later than February 22.

LETTERS TO THE EDITORS

Penicillamine, a Characteristic Degradation Product of Penicillin

WE noticed more than nine months ago that acid hydrolysates of penicillin gave a strong blue-violet coloration with the ninhydrin reagent. Afterwards it was found that, under standardized conditions of hydrolysis, the colour intensity given by numerous penicillin preparations of varying degrees of purity ran parallel to their antibacterial activities except in the case of very crude specimens. It was also found that about 59 per cent of the total nitrogen of the purest preparations could be estimated as amino-nitrogen after one hour's hydrolysis by means of *N*/10 sulphuric acid under the conditions of the van Slyke method. These facts indicated that the substance responsible for the ninhydrin reaction and the positive results in the van Slyke amino-nitrogen determinations was a fundamental part of the penicillin molecule. Its isolation was therefore regarded as a matter of importance and we are now able to report that it has been obtained as a crystalline hydrochloride. The properties of this substance, which we propose to term *penicillamine*, show that it represents a novel type of naturally occurring base. Penicillamine is identical with the base which we have stated in an earlier communication[1] to occur in acid penicillin hydrolysates.

Penicillamine is obtained by hydrolysing barium penicillin (both 650 and 1,000 units/mgm. have been employed) at 100° C. for one hour by means of *N*/10 sulphuric acid, and the base is eventually precipitated from a concentrated solution by mercuric chloride. After de-mercurizing by hydrogen sulphide and evaporation of the solution at the room temperature under diminished pressure, a mass of homogeneous needles is obtained (yield, 30–40 per cent calc. on nitrogen content of penicillin). Analysis (Weiler and Strauss) of material dried *in vacuo* at 50° (loss, $1H_2O$) gave the formula $C_6H_{11}O_4N,HCl$; just conceivably $C_6H_9O_3N,HCl,H_2O$, although the salt did not lose water at 100° in a high vacuum. The molecular weight determined by X-ray crystallographic measurements (private communication by Crowfoot and Low) was in satisfactory agreement with the formulæ $C_6H_{11}O_4N,HCl,H_2O$ or $C_6H_9O_3N,HCl,2H_2O$. It is worthy of note that $C_6H_{11}O_4N$ is $C_6H_{12}O_6 + NH_3 - 2H_2O$.

Penicillamine appears to be optically inactive (19 mgm. in 1·3 c.c. of water) and we take this opportunity of correcting the statement that barium penicillin of 500 units/mgm. is lævo-rotatory; the substance is dextro-rotatory in aqueous solution. The electrometric titration curve of the new base shows the presence of three proton-binding centres, at *p*H 2·0, *p*H 7·9 and *p*H 10·5, respectively. These may be an acidic hydroxyl, the basic group, and a weakly acidic hydroxyl group. The nitrogen is present in an amino-group and is liberated (more than 90 per cent) as nitrogen with nitrous acid in five minutes under the conditions of the van Slyke method. The ninhydrin reaction is an intense bluish-purple coloration.

Other properties of penicillamine, however, are very different from those of the known amino-acids and even suggest a relation to an amino-sugar and ascorbic acid, optical inactivity in that event being due to racemization through enols. Naturally these unusual properties (see below) may be due to substituent groups and do not certainly exclude the presence of a carboxyl group. A typical α-amino-acid structure is rendered improbable by the slow and incomplete formation of carbon dioxide on heating with ninhydrin[2] at *p*H 2·5 (0·2 mol. in ½ hr., 0·3 mol. in 1 hr.; glutamic acid gave 0·95 mol. carbon dioxide in 12 min. under similar conditions). Penicillamine gives a deep blue coloration with ferric chloride which quickly fades owing to oxidation. It reduces ammoniacal silver nitrate on gentle warming and gives a green colour with Fehling's solution. It reduces iodine in cold acid solution, taking up rather more than two atoms of iodine. The change appears to be reversible; for example, the colourless solution renders iodine to ether. This experiment suggests oxidation of a hydroxy-enolic or amino-enolic system or N-iodination. On heating a solution of penicillamine and *p*-nitrophenylhydrazine in *N* hydrochloric acid at 100°, glyoxal-*p*-nitrophenylosazone is produced in about 20 per cent yield. This degradation indicates the source of glyoxal-*p*-nitrophenylosazone obtained in much earlier experiments when penicillin was heated in *N* acid in the presence of *p*-nitrophenylhydrazine. The natural explanation is that a glycollaldehyde fragment has been detached, but it should be observed that fission with formation of formaldehyde would also supply an explanation of this result[3]. In either case the reaction represents an unusual type of decomposition.

Increase in Toxicity of Stilbamidine Solution on Exposure to Light

THE increasing use of stilbamidine (4 : 4′-diamidinostilbene di-β-hydroxyethane-sulphonate) for treatment of kala-azar in the Sudan[1] and India[2] makes the properties of this drug a matter of some importance. Kirk[3] reported that solutions of the drug which had been made up and exposed to light for some time appeared to have increased in toxicity. Fulton and Yorke[4] have confirmed this suggestion experimentally, and our own work, carried out independently as a result of Kirk's observations, has given similar results. Dilute solutions of stilbamidine (0·5 per cent), exposed to sunlight, increase in toxicity four- or five-fold in about four days, after which there is no appreciable further increase. Weak solutions (0·5 per cent) change much more rapidly than do stronger, but by subjecting 10 per cent solutions to the light from a mercury arc lamp for several hours, we have been able to prepare sufficient quantities of toxic solution for isolation of the material responsible for this toxicity.

The toxic diamidine is readily separated from unchanged stilbamidine by precipitating the latter as its sparingly soluble hydrochloride with excess hydrochloric acid. From the filtrate the toxic amidine is precipitated by excess caustic soda as a gum from which the hydrochloride and sulphate have been prepared in pure crystalline condition. Other well-defined salts include the picrate and picrolonate.

The product is almost certainly 4 : 4′-diamidino phenyl benzyl carbinol, but rigorous proof is difficult. This diamidine on heating loses water and ammonia to give *trans* 4 : 4′-dicyano stilbene. At one stage it was thought that the toxic product was *cis*-4 : 4′-diamidinostilbene, but this on heating yields cis-4 : 4′-dicyanostilbene. The different picrates obtained from the two amidines also indicated that this theory was incorrect. On hydrolysis the amidine obtained by irradiation gives an acid, which from analysis appears to be phenyl-benzyl-carbinol-4 : 4′-dicarboxylic acid ; this acid, on successive treatment with thionyl chloride and *o*-toluidine, yields a toluidide identical with that obtained from stilbene dicarboxylic acid similarly prepared.

The toxic product and its derivatives are thus readily converted back to the corresponding stilbene derivatives. The toxic amidine is colourless and exhibits only a slight fluorescence in ultra-violet light, whereas '*cis*-stilbamidine' exhibits an initial weak fluorescence which is intensified in a few seconds until comparable with that of the *trans*-compound.

It seems probable that the reaction occurring in aqueous solution is an addition of the elements of water to the double bond of the stilbene linkage. It is possible that the function of the ultra-violet light is first to convert some of the trans-stilbene to the cis-compound, which is the more reactive form.

It follows from the above, and the fact that other therapeutic diamidines have shown no such alteration in biological or chemical properties, that the change is associated solely with the unsaturated stilbene linkage, and that the amidine groups are not affected.

The biological results obtained with the isolated and purified toxic diamidine are in conformity with those of the exposed solutions. The symptoms produced in mice by the toxic substance were more stimulant in character than those caused by a freshly prepared solution of stilbamidine, which were mainly depressant. In general, the pharmacological effects shown by the toxic product differed quantitatively rather than qualitatively from those of the original substance. The depressor action in the anæsthetized cat was increased about five times, and recovery was delayed. Atropine only partially antagonized this effect, while the spleen was actively contracted. Smooth muscle of the rabbit intestine was sometimes contracted in concentrations of about 1 : 50,000, but after atropine, inhibition and relaxation were always produced; this differed from the effect of stilbamidine, which caused contractions which were only slightly reduced after atropine. The fall of pressure was probably mainly due to vasodilatation, since there was no depressant action on the isolated rabbit's heart. The isolated product had a toxicity in mice which was five times greater by intravenous injection, and ten times greater by subcutaneous injection, than stilbamidine. Of great importance was the observation that the toxic product was almost inactive therapeutically against *T. equiperdum.*

There are many interesting features of the phenomenon which we propose to examine at a more favourable opportunity. For example, it is almost certain that at least one other product of irradiation, a yellow compound, is formed in small quantities ; the appearance of a yellow colour in the solution is particularly marked in the case of slow irradiation in natural light. We also intend (in view of the findings of Kirk[3]) to see whether prolonged administration of therapeutic doses of the toxic product causes pronounced liver damage.

The nature of the changes occurring on exposure of solutions of stilbamidine emphasizes the necessity for use of freshly prepared solutions of this drug, especially when it is realized that a marked increase in toxicity is apparent after only two or three hours standing in daylight.

Antimony Content and Toxicity of Urea Stibamine

UREA STIBAMINE, introduced by Brahmachari[1] in 1922 and widely employed in the treatment of kala-azar in India and elsewhere, still remains a compound with no definitely known and agreed chemical formula. It was originally reported to be a substance composed of urea and *para*-aminophenylstibinic acid with the empirical formula, $C_7H_{12}O_4N_3Sb$. Later it was suggested that the compound was identical with ammonium-*para*-carbamidophenylstibinate, $NH_2.CO.NH.C_6H_4.SbO(OH).ONH_4$ [2]. Ghosh *et al.*[3] and Gray *et al.*[4] gave definite evidence that urea stibamine was not a single substance of definite composition and the latter group of workers showed that the 'effective active principle' was a di-substituted urea, *S*-di-phenyl-carbamide-4 : 4 distibinic acid. The antimony content of various commercial samples was shown by Ghosh *et al.* to vary between 20 and 43 per cent, while Gray *et al.* reported a comparatively smaller range of variation in antimony content from 44·19 to 48·6 per cent. Brahmachari[5] appeared to have accepted the results of Gray *et al.* in this regard, and emphasized that the divergent results obtained by different investigators were due to different brands of "so-called urea stibamine", not conforming to his original specifications; being put on the Indian market.

In connexion with the routine testing of drugs on behalf of the Director-General, Indian Medical Service, this laboratory had an opportunity, during the years 1940–42, of testing more than a hundred samples (with different batch numbers) of urea stibamine manufactured by the Brahmachari Research Institute, Calcutta. Chemical assay for antimony content (Ghosh[6]), and toxicity tests (Burn[7]) on white mice were regularly carried out. In a few specimens, survival time of infected mice (*T. equiperdum*) was also recorded according to the method of Gray *et al.* (*loc. cit.*).

A critical analysis of our data shows that, in general conformity with the findings of Gray *et al.*, the antimony content of urea stibamines (Brahmachari) is fairly constant and lies between 39 and 42 per cent. In only five instances (out of 100 analyses) was a figure above 42 per cent (but less than 44) found. In only one case, a figure below 39 per cent antimony was obtained. However, our maximum figure was definitely *lower* than the minimum figure (44·19 per cent) of Gray *et al.*[4].

Napier[8] found that the lethal dose of urea stibamine for mice was 250 mgm. per kgm. body weight. Though an accurate statistical analysis of our mean lethal dose figures has not yet been made, it is possible to state that in the majority of our experiments a toxicity figure varying between 200 and 225 mgm./kgm. was recorded. The maximum tolerated dose was often in the neighbourhood of 150 mgm./kgm. and seldom exceeded 170 mgm./kgm. Specimens containing a higher antimony content apparently showed a higher toxicity and stronger therapeutic effect, but a statistically significant relationship between antimony content and toxicity could not be established.

Work is in progress to find out whether, in view of its fairly constant composition (within the limits stated above), urea stibamine can be employed as a *standard* for evaluating the potency of other pentavalent organic antimony compounds of similar composition manufactured in India. The absence of an international standard of unvarying composition for antimony, as in the case of organometallic compounds of the arsenic group, is keenly felt by workers engaged in drug standardization in India.

Configuration of Purine Nucleosides

HENDRICKS[1] has measured the interplanar cleavage spacings, *d* (001), of a number of organic salts of the clay mineral montmorillonite by means of nickel $K\alpha$ radiation. Among the cations studied were those of the purine bases guanine and adenine and the corresponding nucleosides guanosine and adenosine, which are 9-guanine *d*-ribofuranoside and 9-adenine *d*-ribofuranoside respectively[2]. By his measurements Hendricks showed that the arrangement of the atoms of the two purine ions is coplanar, thus confirming the view which is reached from consideration of molecular models. He also concluded that the nucleoside ions have a van der Waals 'thickness' between oxygen centres (of montmorillonite) only about 1·0 A. greater than would be required for a strictly coplanar atomic arrangement, and that the purine and sugar radicals of the nucleoside ions lie in two parallel planes about 1·5 A. apart, with the majority of the atoms lying probably in or near the two planes; one plane contains the purine radical, the other the ribose ring, and it is held that the hydroxyl groups as well as the primary alcohol group must be approximately in the plane of the purine radical, in order to accommodate this close lateral packing of atoms.

Hendricks thus postulates that in the nucleoside montmorillonites the hydroxyl groups at C_2 and C_3 of the pentofuranoside and the primary alcohol group C_5 are in the *cis* relationship with reference to the plane of the furanose ring, whereas in the ribofuranosides the configuration is such that the hydroxyl groups are both *trans* to C_5; in fact, the sugar shown in Fig. 8a[1] is not a ribofuranoside but is a lyxofuranoside. Nevertheless it is generally accepted that the sugar in these nucleosides is *d*-ribose, and further proof of this identification will shortly be published elsewhere in so far as the pentose of the four nucleotides of the ribonucleic acid of yeast is concerned. Nucleotides from other sources are being similarly examined.

Consequently, there would seem to be two alternatives. (1) The sugar in the nucleoside ions examined was actually *d*-ribose; if so, the conclusions of Hendricks may require revision to accommodate the fact that either two hydroxyls or one primary alcohol group, depending on the as yet unsettled α- or β-configuration of the glycosidic linkage, will lie outside the plane of the furanoside ring, *trans* to the purine radical and at a distance from the furanose plane about the same as that separating it from the purine plane. (2) The sugar in the nucleoside ions examined was in fact α-lyxose; in this case the position would be that the pentose in the nucleosides (nucleotides) may not always be *d*-ribose, a possibility which we have suspected for some time. In this connexion it may be mentioned that two of us have isolated *l*-lyxose in the form of a derivative from yeast ribonucleic acid; the details and significance of this observation will be discussed elsewhere. The material source of the nucleosides examined by Hendricks was not stated.

Newt Larvæ in Brackish Water

IT is generally believed that amphibian larvæ are not found in salt or brackish waters, and therefore the following observation seems interesting.

On August 7, 1942, newt larvæ were observed in one pool of the many on the western side of Carradale Bay, Argyll. The pool was about nineteen yards from the nearest salt water pool on a gently sloping shore. Its bottom consisted of rock and shingle and it was surrounded by turf. It was fed by rain and seepage. A sample taken contained chloride equivalent to 0·28 per cent sea water. This is regarded as a fresh water.

On August 18 a neap tide came to within nine yards of the pool. During the night of August 18–19 there was a considerable wind, and judging from the line of jetsam the sea had reached this pool, which had increased in size. It was measured roughly on August 20. It was L-shaped round the base of a large rock. The long arm of the L, parallel to the sea, was about 20 ft., and the short arm, directed landward, 10 ft. long. It was less than 4 ft. wide and the greatest depth was less than 3 ft.

The water was visibly layered. A sample from the shallower parts contained 5·6 per cent sea water and from the bottom of the deep parts 68·3 per cent sea water. The newts congregated in the lower levels of the shallower parts, but occasionally swam through the deep water. Thirteen newts lived twenty-four hours in the 5·6 per cent sample, but one newt put into the 68·3 per cent died within 1 hour 40 minutes. On August 20, after rain in the night, no dead newts were seen in the pool and a further sample of unanalysed shallow water was taken and added to the 5·6 per cent sample. The newts lived in this until August 22, when it was diluted with the 0·28 per cent sample.

One larva metamorphosed and left the water on August 26, and others did so in the next few days. Therefore the newts seem to have completed their larval development in conditions in which the salinity could rise considerably.

I think there were between 100 and 200 larvæ in the pool. They were of many different sizes.

According to the taxonomic tables of Werner and Herter in "Fauna von Deutschland", edited by P. Brohmer, the larvæ were of *Molge palmata*.

The only other common animal in the pool was a species of Gammarus which did not avoid the salter layers. According to the criteria of Chevreux and Fage, "Faune de France", **9**, and of Stephenson, "Tierwelt der Nord und Ostsee", **10f**, the species was *duebeni*, but the taxonomy of this genus is still fluid.

I wish to thank Mr. J. B. Cragg of the School of Agriculture, University College of North Wales, Bangor, for analysing my samples.

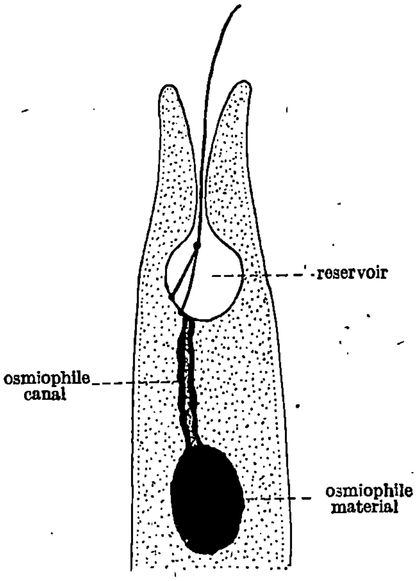
Golgi Apparatus in *Astasia Harrisii*

IT is well known that in numerous Protozoa, the contractile vacuole is associated with an osmiophile cortex, which is believed to be homologous with the Golgi apparatus of metazoan cells. In Paramecium, it has been shown by Nassonow[1] that the secretory canals leading into the contractile vacuoles are osmiophilic in nature, and are considered to represent the Golgi apparatus in this form. Although many Protozoa possess similar canalicular systems, canals with osmiophile walls have never since been demonstrated in any other Protozoon, although a great number have been investigated.

By making Golgi preparations of *Astasia Harrisii* (Pringsheim), a euglenoid flagellate, using the usual Weigl technique for Protozoa[2], I have shown that such an osmiophile canal is present in this organism. It runs from the base of the reservoir, ending in a large mass of osmiophile material approximately spherical in form.



Its general morphology is very similar to that of a single canal of Paramecium, being globulated throughout its length, and is evidently concerned with secretion or excretion into the reservoir.

The Encephalophone: a New Method for Investigating Electro-Encephalographic Potentials

THE usual methods for investigating electro-encephalographic potentials consist in applying the amplified potentials from the head either to a directly recording oscillograph or to a cathode ray oscillograph with photographic recording. The permanent records thus obtained are of value for the purpose of research into the physiological and pathological functioning of the brain, and the results of such researches are becoming of definite clinical value. We wish to suggest a new apparatus for use in the clinical application of electro-encephalography as distinct from the application to research, where recording instruments are essential; it is meant, at its present stage, merely as an auxiliary to the established methods.

The principle of the suggested method is to convert the potential changes from the head into changes of pitch of a musical tone. In an instrument constructed by us, this tone is produced by two independent high-frequency valve oscillators of slightly different frequencies of the order of 5 mc./sec. These are 'mixed' by means of a mixer valve, thus producing a beat frequency equal to the difference between the two high-frequencies. If this beat frequency is in the audio range, it can be made audible as a tone of certain pitch in a loud speaker or pair of earphones. One of the two high-frequency oscillator circuits is connected to a 'frequency modulator' valve which acts in such a way that a change of the control-grid potential of this valve produces a change in frequency of the oscillator to which it is attached. This results in an alteration of the beat frequency and thus in a change of pitch of the tone heard. The potentials from the head are amplified in the usual way by means of a linear amplifier designed for very low frequencies, before applying them to the frequency modulator valve. We propose to call this instrument an 'encephalophone', following a suggestion by Dr. George Dawson.

The instrument has been tried out and found to work very satisfactorily. Both 'alpha' rhythms and 'beta' rhythms give characteristic trills, while the three per second and other slow waves usually met with under pathological conditions produce correspondingly slow sweeps of tone which are very striking and readily appreciated. There seems little doubt that the method is adequate for most diagnostic purposes to which the graphic method has so far been successfully applied. Further, there are some distinct advantages of the audio method over the present graphic ones. The apparatus, consisting of valves, batteries, etc., can be built in one compact unit, which is very inexpensive and easily portable. Secondly, in the audio method the observer's visual system is left free to watch for the slight movements of the subject's body which produce artefacts in the electro-encephalic potentials; this is of especial value in the examination of non-co-operative subjects.

As a possible future development, the two ears of the observer might be used for two 'channels'. The inputs to these two channels could be taken from symmetrical regions in the two hemispheres of the head, and it is probable that a departure from symmetry in frequency or size of rhythm, or even in phase, could be detected in this way. The observation of phase-relationships in any two regions could also readily be undertaken by the audio method employing two channels.

Our thanks are due to the University of Edinburgh, to the Rockefeller Foundation and to Mr. Norman Dott for the opportunity of doing this work.

The Eclipse of the Sun in A.D. 45

ON the few occasions when eclipses of the sun are stated to have been predicted in ancient history, it has generally been found that these took place in the afternoon and could have been predicted as recurrences of the eclipses seen in the morning eighteen years earlier. This argument cannot be applied to the eclipse of August 1, A.D. 45, which certainly took place in the morning at Rome. It could not have been predicted from the eclipse of July 22, A.D. 27, which was not visible in any part of Europe. The assertion is that the Emperor Claudius issued a proclamation stating that the eclipse was expected, with full explanations, so that it should be regarded as a natural event and neither a prodigy nor a bad omen. Both the Emperor and his scientific adviser must have been quite certain of their facts, because they could not take any risk of failure.

I am not aware that anyone has investigated this eclipse before me, and I was rather surprised and impressed when my calculations led to the result that it took place in the morning. It must be inferred that the knowledge of astronomers at that time concerning the eighteen-year period was something more than the simple and elementary ideas usually ascribed to them. They must have understood that eclipses inevitably recur at these intervals, although they may be visible only in distant parts of the earth. If they really knew that after three such periods the eclipse must reappear in its former locality, we have to believe that they had some knowledge of the dimensions of the earth and of that which we now call longitude.

At Rome the maximum phase was at 10.36 a.m., local mean time, and the magnitude thereof was 0·35 of the sun's diameter. The central line, where the eclipse was total, passed a long way south of Italy, far down in Africa. As to who the learned man who coached the Emperor may have been, I would suggest that while there was a frequent service of shipping between Ostia and Alexandria, bringing grain to Rome, it would be easy to communicate with the astronomical fraternity in Egypt, as Julius Cæsar actually did, when requiring advice on the subject of reforming the calendar, a century before Claudius.

Sir Henry Miers

SHOULD it not be recalled that Sir Henry Miers gave the clue for the discovery of terrestrial helium? In 1868, Norman Lockyer, founder and first editor of NATURE, observed in the spectrum of a solar prominence the characteristic yellow line of helium, previously unknown. In 1888, Dr. Hillebrand, of Washington, discovered that the mineral uraninite treated with sulphuric acid gave a gas which he suspected to be nitrogen. On the discovery of argon in 1895 by Rayleigh and Ramsay, search was made for sources of nitrogen, and Miers suggested to Ramsay examination of the gas discovered by Hillebrand. Ramsay sent a sample to Crookes for spectroscopic analysis: Crookes said "This is helium".

Last year, I congratulated Miers on his long innings, suggesting that he could survey his Agar's Plough with satisfaction and that in giving the clue for the discovery of helium, he hit the ball over the pavilion. "Oh, no!" he replied with characteristic modesty, "the helium episode is only a timid but lucky swipe which happened to sneak through to the boundary." In another letter he declared, "I don't really care two straws about credit for what was really a fluke".

RESEARCH ITEMS

Avian Phylogeny

As the result of detailed anatomical investigations, more especially into the flexor carpi ulnaris, flexor sublimis digitorum and other muscles in the struthious birds and the Tinamous, Percy R. Lowe (*Proc. Zool. Soc. Lond.*, B, **112**; 1942) has come to certain general conclusions regarding the relationships of these groups to the rest of the birds (the Neognathæ). The author states that his findings do not favour the view, associated particularly with the names of Fürbringer and Gadow, that the various groups of struthious birds have evolved independently, but on the contrary they are to be regarded as a more closely knit group. Moreover, it is not possible to regard them as having arisen from a volant stock that has become modified owing to the loss of the power of flight. Among other things, the sternum ossifies from two centres one on each side related to the fused ends of the ribs, and there is no sign of the median Lophosteon from which the keel of the sternum of the carinate birds develops. Nor is neoteny, as de Beer suggested, an explanation of the conditions found in struthious birds, for the arrangement of the muscles bears practically no resemblance to those of the chick in any flying bird; it is on an altogether lower plane and gives no indication of an ancestral power of flight or the possibility of the development of such a power in the adult. The tinamous (Crypturi) also are to be looked upon as Palæognaths, but volant types where the attempt at flying was more successful than in other types, and even at that not so successful as in the case of the characteristic carinate birds. While the bones in the palate of Hesperornis are not satisfactorily established, the author suggests they are probably to be regarded as aquatic Palæognaths.

Nephridia of Earthworms

To zoologists whose knowledge of the excretory system of the Oligochæta is based upon the condition in Lumbricus it may come as somewhat of a surprise to learn that the terminal portion of the nephridium, the bladder, is not present in a number of genera. It is still more surprising to learn of the great variety of form and arrangement of the nephridia that are to be found within the limits of the group; indeed they are more variable than any other organs. Two main types are to be recognized, which Bahl has termed exonephric and enteronephric types; the former opening directly or by means of a longitudinal, common duct to the outside and the latter opening by means of ducts into the lumen of the gut. K. N. Bahl (*Quart. J. Micro. Sci.*, **83**, Pts. III and IV; 1942) has provided a description of the nephridia in the sub-family Octochætinæ, and this is prefaced by a useful review of the various types of nephridia encountered in the Oligochæta and also some details as to their development. The same author in the same journal has a second paper dealing with the multiple funnels in the nephridia of *Thamnodrilus crassus*, *Hoplochœtella bifoveata* and *Lampito* (*Megascolex*) *mauritii*, which form an interesting, graded series.

British Species of Ephemeroptera or Mayflies

Scientific Publication No. 7 of the Freshwater Biological Association of the British Empire is entitled "Keys to the British Species of Ephemeroptera with keys to the Genera of the Nymphs", by D. E. Kimmins, Dept. of Entomology, British Museum (Natural History), 1942. The appearance of this well-illustrated pamphlet will be welcomed by entomologists and others, since it provides for the first time a reliable means of identifying these insects. It should stimulate their collecting and observations so that an accurate idea may be obtained regarding the distribution of the different species. Altogether forty-seven species are claimed as being British, but there is no doubt that intensive collecting and observation will bring to light others in the future. Knowledge of the nymphs or immature mayflies is as yet insufficient to enable satisfactory keys to be devised for the determination of the various species. It is for this reason that a key to the identification of the genera only is provided. Most species of mayflies occur in Britain, under suitable conditions, in enormous numbers, and in all stages of their life-cycle they form a very important constituent of the food of freshwater fishes. This and other publications of the Association are free to members of that body. To non-members it is obtainable from the Director, Freshwater Biological Association, Wray Castle, Ambleside, Westmorland, price 2*s.* 6*d.* Membership of this body, it may be added, is open to any who sympathize with its objects, the minimum annual subscription being £1.

Oxidation of Ascorbic Acid in Tea

During an inquiry into the suitability of certain articles of food as carriers of ascorbic acid, it was found that condensed milk, to which synthetic ascorbic acid had been added, lost its antiscorbutic activity when mixed with tea. In their efforts to prevent this destruction, G. A. Snow and S. S. Zilva (*Biochem. J.*, **36**, 641; 1942) established that inactivation of the ascorbic acid was due to the presence of certain non-metallic organic compounds, associated with the tannin fraction, capable of catalysing the oxidation of ascorbic acid in the presence of oxygen. Commercial gallic acid showed some activity, whereas *d*-catechin, tannic acid catechol, quinol and pyrogallol were almost inactive. Milk, egg albumen, cysteine and to some extent dimedone, inhibited the catalytic activity, and sodium chloride and potassium iodide accelerated it. Substances of a similar catalytic nature may be present in other vegetables and fruit tissues either originally or after treatments such as cooking or drying. For example, aqueous acetone extracts of the root and stem of rhubarb, and aqueous infusions of the dried leaves of rhubarb and camellia were active. Should the presence or formation of these catalytic substances in vegetables and fruits be fairly common, it would add one more factor to those which have to be considered in connexion with the stability of vitamin C in vegetables and fruits.

Comparative Morphology of the Algæ

Numerous cases are reported of parallel development among algæ; in this connexion stress is usually laid mainly on the simpler types of plant body, but F. E. Fritsch now directs attention to the very wide occurrence of the heterotrichous habit among those algal groups which have attained a higher degree of specialization than the simple filament (*Ann. Bot.*, N.S., **6**, No. 23; July 1942). Though exhibited in many algal groups, this habit is perhaps of most interest to follow in the Phæophyceæ and Florideæ; here the heterotrichous condition appears as the adult form or as a juvenile condition in the Ectocarpales and Nemalionales, but the prostrate system tends to become reduced and finally to disappear in the most specialized members of the groups (for example, Ceramiales), but persists in intermediate groups, especially in the gametophyte. The filamentous stages of some of the larger Ectocarpales, derived from spores from plurilocular sporangia on the sporophytes (plethysmothalli), seem best explained as sporophytes arrested for a considerable time in the heterotrichous, juvenile condition and distinct from the filamentous gametophytes derived from spores from unilocular sporangia. Cutleria, which is exceptional among algæ in showing alternation of two different macroscopic phases, shows, in intermediate forms which are described, evidence of origin from a heterotrichous type, in which the sexual generation has lost the prostrate, and the asexual the erect, part of the system, though traces of the latter persist as the column which is formed early in the development of the 'Aglaozonia' stage sporophytes.

Factors in the Production of Leaf Palisade Tissue

A VERY interesting contribution to our knowledge of this subject is made by R. W. Watson (*New Phyto.*, 41 (3), October 1942). Using cuttings of the juvenile form of ivy, it was possible to initiate the production of palisade in fully expanded leaf blades by transferring them from a shaded to a brightly lit habitat. If transfer was sudden the layer of mesophyll cells immediately below the upper epidermis, with the exception of those nearest to the veins, might be killed, evidently through desiccation. A more gradual or less violent adjustment of light was shown first by an accumulation of starch, then in the upper cell ayers starch disappeared with a growing concentration of sugar in the cells, and this was followed by water absorption and an increase in length at right angles to the leaf surface as characteristic palisade tissue was developed.

Luminosity a Mendelian Character in a Fungus

RUTH MACRAE confirms (*Canad. J. Res.*, 20(8), August 1942) previous observations that whereas the mycelium of *Panus stypticus* in Europe is non-uminous the North American form is luminous. Both forms are heterothallic and all pairings between monosporous mycelia from the two forms seem to be fertile. It has thus been possible to show, by crossing luminous and non-luminous forms, that this s an inherited character governed by a single pair of Mendelian characters and that luminosity is dominant and is expressed as a dominant character n the binucleate mycelium in the *F*1 generation.

ystems with Boron Trifluoride

THE boron atom of BF_3 acts as an acceptor of lectrons to form a large number of co-ordinate compounds. Atoms which act as donors of electrons are arbon, nitrogen, oxygen, fluorine, phosphorus, ulphur and argon. H. S. Booth and D. R. Martin *J. Amer. Chem. Soc.*, 64, 2198; 1942) find that HCl nd CH_3Cl give only eutectics and no compounds with BF_3, so that the reported compound $BF_3,3HCl$ s non-existent. Nitrous oxide N_2O forms no compound with BF_3. Sulphur dioxide SO_2, as in the ase of solvents H_2O and NH_3, forms a compound BF_3,SO_2 and two eutectics. The structure suggested is an ionic one $[SO]^{++}[OBF_3]^{--}$ analogous to the monohydrate $H^+[HOBF_3]^-$, although the formula $O_2S \rightarrow BF_3$ is also possible and would agree with the formation of the compound $H_2S \rightarrow BF_3$.

X-Ray Elasticity Measurements for Mild Steel in Compression

THE X-ray study of elastic properties of metals is continued in a paper by S. L. Smith and W. A. Wood (*Proc. Roy. Soc.*, A, 181, 72; 1942). Mild steel specimens were used in a standard 10-ton testing machine, and the X-ray tube was built up alongside in a position suitable for taking back-reflexion photographs. The external strain measured by an extensometer was compared with the changes in diameter of a sensitive X-ray diffraction ring formed by back-reflexion of beams incident perpendicular to the length of the specimen and to the direction of stress. It is concluded that the lattice possesses a yield point also in compression, again marking the onset of a permanent lattice strain. The direction of this strain is opposite to that found in tension and the magnitude increases systematically with the applied stress. Experiments on pure iron suggest that the mechanics of the metallic lattice involve the principle that, after the lattice yield point, in a given direction the lattice systematically assumes a permanent strain in such a sense as to oppose the elastic strain induced by the applied stress.

Abrasion Test for Textile Threads

A. C. WALKER, writing on this subject (*Bell Lab. Rec.*, 21, No. 1; September 1942), refers to studies made in the Bell Laboratories on the resistance to abrasion of threads of different materials such as are used for the braided covering of telephone cords, and of treatments to improve the life of the braids. One test is carried out by an abrasion apparatus which wears threads or braids until they break, the time required serving as a measure of wearing qualities. Threads tied in endless loops are suspended from hooks fastened to a stationary cross-bar. Square weights are hung from the loops and the threads are then arranged about staggered pins mounted on a movable plate, being looped around the middle pin so that they twist together in a sharply bent loop. As the movable plate oscillates up and down under the action of a motor-driven cam, it rubs the threads against each other and wears them at the sharp bend. It is important to have two threads in parallel to minimize the tendency of the single strands to twist and untwist during the rubbing action. The threads are prevented from twisting about one another by resting the square weight lightly against a backing plate. The cabinet which encloses the apparatus is air-conditioned for controlled humidity and temperature. Seventeen samples can be tested at a time. One of the chief limitations to the reproducibility of results attainable in testing textiles is the lack of uniformity in the materials. In measuring the abrasion resistances of spun mercerized cotton used for telephone cord braids, the method described gave consistent results within ± 15 per cent of the average for groups of seventeen samples. This is considerably better than might be expected on the basis of the variability in the spun yarn, as shown by analyses of the results of several hundred tests. Because the time required to test threads is short compared to testing finished cords, this method lends itself to rapid preliminary studies for improving wearing qualities.

AGRICULTURAL EDUCATION ASSOCIATION

ANNUAL CONFERENCE

IT was quite evident from the attendance at the Midland Agricultural College during January 4–6 that the Council's decision to resume the normal conferences was a popular one, for some seventy-five members arrived to take part in the discussions. Two years ago it had been decided to suspend most of the activities of the Association because of difficulties consequent upon numerous members being drafted from their usual activities into the service of war agricultural executive committees, to the disorganization of agricultural colleges and university departments due to changes in policy thrust upon them in the early days of the War, transport difficulties and so on. But as time went on, it became obvious that the multitudinous problems now besetting the agricultural scientist and educationist would have to be discussed by as many people as possible, and the recent conference was the outcome of the demand.

Prof. R. G. White, University College of North Wales, Bangor, presided at the two paper-reading sessions. It is not possible to do more than indicate the general lines of the more important matters discussed, but the papers presented will be published in full in the Association's journal *Agricultural Progress*. The discussion which took place upon agricultural education in rural areas is not included in this brief summary, but will receive special attention in another issue of NATURE.

Three papers of outstanding value dealt respectively with drainage, seeds and milk. On the subject of drainage, Mr. H. H. Nicholson, of the School of Agriculture, Cambridge, dispelled any feelings of complacency there might be in various quarters by stating that we are not draining agricultural land in Britain very much faster than we were during the period 1864–72; at that time some 44,000 acres annually were being intensively 'tile drained', whereas now, at a time when we are fighting for our lives on the agricultural front, only about 124,000 acres have been scheduled in two years, and the drainage could scarcely be called intensive. He complained, too, of the timid approach to mole draining in many counties. Soil conditions for mole draining, he said, are at their best in March, April, May and June, when the surface is firm enough to allow easy passage of implements and the subsoil is moist enough for the mole to function properly. He deprecated the warning off of the mole plough during these months simply because the ground is occupied by a straw crop, for in his opinion very little damage would be done to the crop by moling over it. He would like to see more attention being paid to the principles of drainage in agricultural courses at colleges and universities.

The vital question of seed supply in war-time received attention from Mr. L. E. Cook, executive officer to the Seed Production Committee of the Ministry of Agriculture. He showed first that in normal times we receive seeds from all parts of the world and produce only a small amount ourselves. At the outbreak of war, we were cut off from European supplies, while supplies from America and New Zealand and other countries were gravely threatened. To ensure sufficient seeds the Government has had to interfere with the usual trade arrangements whereby individual firms buy where and as they choose, and substitute a system whereby the Government does all the buying in the national interest. Mr. Cook stressed the necessity for looking well ahead when dealing with seeds, saying that the next planting of seeds for seed crops such as mangold, onion, sugar beet will not produce seeds for sowing until 1945, and that from the sowings of cocksfoot in the spring of 1943 a full crop of seed will not be available for use before the spring of 1946. On the home production front, there are now twenty-seven seed growers' associations in existence, and the Government has fixed acreage targets for many kinds of home-produced seeds. The all-important thing is to have a sufficiency of seeds, and this may mean excessive production in a favourable seed-producing year; it is consequently necessary for growers' prices to be safeguarded.

In two closely related papers, Prof. H. D. Kay and Dr. J. G. Davis, of the National Institute for Research in Dairying, explained the National Milk Testing and Advisory Scheme. Prof. Kay described how in the early part of 1942 an advisory committee representative of the Ministries of Agriculture, Food and Health, of the Milk Marketing Board, the National Farmers' Union, the Central Milk Distributive Committee and the County Councils' Association prepared a nation-wide scheme to maintain a satisfactory standard of quality for all milk supplies; to reduce loss of milk from souring; to arrange for unsatisfactory milk to be manufactured or otherwise salvaged, or to be rejected and returned to the producer; to provide a basis for the introduction as soon as possible of a scheme of differential prices to producers in accordance with the keeping quality o the milk, and to provide information to enable county and provincial advisory services to be used to the best advantage. Such a scheme had become urgently needed because of the enormous amount o milk which is being lost every summer in Grea Britain through premature souring, a loss which i destroying the efforts being made throughout the country to increase milk production.

Before such a scheme could be put in operation i was necessary to devise some simple and *rapid* tes in order to weed out milk that fell below a certain standard. Dr. Davis described how in 1941 a comparison of all the recognized quick tests was completed by a panel of advisory dairy bacteriologists with the result that the 'ten minute resazurin test was officially recognized. Prof. Kay claimed that in spite of war-time difficulties and the fact that th whole country has not yet been covered, the schem is already bearing fruit. Two of its main objects ar to improve the standards of the lower 50 per cent o milk producers in Great Britain who have hithert had little help or advice, and to better the techniqu of milk handling in the many larger and smalle collecting units where methods are at present unsound. He saw a point of very great significance in that here, probably for the first time in the history of dairying, all sides of the industry and all th Government departments concerned are freely co-operating to achieve a single purpose, the permanen improvement in the keeping quality of the nation' milk supply. A later speaker described this schem as a perfect example of the application of science t a particular problem—first the examination of th data, then the search for a solution and the testin thereof, and finally the devising of machinery to apply the solution to the industry as a whole.

Another paper of considerable scientific interest was contributed by Mr. W. Morley Davies, of Harper Adams Agricultural College, who reviewed the present knowledge of crop failures caused by deficiencies of the minor elements in the soil. Such failures have been noticed in very many counties, and although they cannot be regarded at present as of major economic importance in the British Isles, further information concerning them is greatly needed. The commonest deficiency diseases in crops are those due to shortages of manganese, magnesium, boron and iron, and Mr. Davies was able to describe, with the aid of slides in colour, the characteristic symptoms of each disease. When recognized, the first three diseases can be controlled by application of manganese salts, magnesian limestone and borax, respectively. Mr. Davies mentioned that, certainly in the case of manganese and boron deficiency, over-liming tends to accentuate the symptoms, and while it is to be hoped that this statement will not interfere with the liming programme that is so urgently needed in many parts of Great Britain, it must be recognized that in certain circumstances and on certain soils lime is definitely harmful. One complaint caused, not by a deficiency but by an excess of a minor element, is 'teart'. Teart describes the scouring which takes place when cattle are turned out on certain pastures in Somerset, Warwickshire and elsewhere. It has recently been discovered that excess of molybdenum in the herbage of such pastures is responsible for the trouble; dosing the cattle with small amounts of copper sulphate is the remedy.

Wireworm problems were dealt with by Mr. W. E. H. Hodson, of the University of Reading, and Mr. D. J. Finney, of Rothamsted Experimental Station, the latter applying himself more to the statistical examination of data provided by the recent wireworm survey. From these two papers it appears that the present method of sampling fields for wireworms is reasonably accurate; it involves the collection and examination of twenty randomized cores, each 4½ in. in diameter and 6 in. deep, per field (fields of more than 50 acres are treated as two fields). Populations below 300,000 per acre can be disregarded except for maincrop potatoes; populations between 300,000 and 600,000 are dangerously high for many crops; between 600,000 and a million wireworms per acre are likely to be serious, while populations of more than a million render the likelihood of a good crop fairly remote. The speakers did not claim that the wireworm problem has been solved, but much progress has been made. As Mr. Hodson pointed out, the mere knowledge of a high population leads to extra care and extra cultivation, and so there is a better chance of a good crop.

In a summary of the present position of silage-making, Mr. W. McLean, of the University College of North Wales, thought that the actual making of silage demands greater attention than has hitherto been given to it. The results achieved to date indicate clearly that the underlying principles of the modern silage process must be more thoroughly understood by farmers in general before good quality silage can be produced generally. He thought that the 1940 silage campaign had rushed the farmers into an improperly understood operation, and the consequent failures had done the movement much harm.

Speaking on the subject of artificial insemination centres for dairy cows, Dr. S. Bartlett and Dr. J. Edwards said that the advantages of artificial insemination are now widely appreciated, and these are particularly evident in the case of small dairy herds where the keeping of a bull is uneconomic. Two Government-sponsored centres are in existence, at Cambridge and at Reading, and these are expected to yield information of considerable value and to provide pointers for lines of future development. Shorthorn and Friesian bulls are kept at Cambridge, and at Reading there are Guernseys as well. It seems clear that if a high grade of bull is to be kept and proper control of disease is to be maintained, the cost is likely to be of the order of 30*s*. per cow inseminated.

SYNTHETIC TEXTILE RESEARCH IN GERMANY

In June of last year (1942) orders were given in Germany that scientific workers there and in the occupied countries should confine their activities solely to research that would give immediate practical results. Assuming that there is any real validity in the oft-attempted distinction between fundamental or pure science research on one hand and the immediately useful on the other, it still remains a matter of considerable difficulty to predict whether or no a particular piece of research will yield immediately practical results. The question cannot be pursued here. The main point of interest is that, despite strict orders, the artificial textile research workers in Germany have just expressed their profound conviction that fundamental research, in that particular field at least, is of the utmost importance, and must be pursued, even under war conditions, with greater zeal than ever before. This was the dominating note of the fourth meeting of the Zellwolle- und Kunstseide-Ring at Weimar, and was emphasized by the Government representative himself, Staatsrat Dr. Schieber, in his opening address[1].

The Zellwolle- und Kunstseide-Ring was established a few years ago as a kind of study circle by the leading technical schools and universities in Germany, to the meetings of which leading specialists in the different branches of textile research are invited to read papers and initiate discussion. At this fourth meeting, in September last, it was claimed that much hitherto unpublished work of considerable interest was presented, especially in connexion with cell structure as revealed by the latest methods of electronic investigation.

This latter formed the subject of several papers, beginning with that of Dr. E. S. Schiebold, of the Leipzig school, on the use of the electron microscope for the study of organic molecules of the macromolecular type; followed by Dr. L. Wallner, also of Leipzig, on ultra-microscopic and X-ray work on cellulose structure; and by Dr. F. Gunther, on ultra-microscope studies of the polyamides and polystyrol. On the basis of numerous analyses and calculations of the kind described in these three papers, an attempt has been made to arrive at much more accurate and complete models of cell structure in natural and artificial fibres.

Problems of size, position, and spacing of the individual elements—molecules or molecular groups—especially in the softened or dissolved state, were discussed by Prof. Kratky, of the Kaiser Wilhelm

---

[1] *Chemiker Zeitung*, 28, Oct. 1, 1942.

Institute for Physical Chemistry at Dahlem, who had used the so-called small-angle dispersion in his X-ray work.

Probably the greatest name, on the Continent at least, in macromolecular physics and chemistry is that of Dr. H. Staudinger of Freiburg i. Br., who recently completed his three hundredth paper on the subject. At Weimar, he reviewed his work on cellulose and introduced the results of his latest research on the relation between molecular chain-length and strength of fibre in the polyamide group. He referred also to the viscosity of dilute solutions of these products, a matter with which he had previously dealt in considerable detail, under the heading of molecule-colloids. Dr. F. H. Müller, of the University of Leipzig, dealt with specific viscosity in relation to structure in solutions; and Dr. Moll, of Berlin, discussed some differences between ordinary cotton and various artificial *Zellwollen*, and the effect of spinning methods, degree of polymerization, etc., using density measurements of the greatest accuracy. New methods of measuring these various factors were disclosed by Dr. A. Marschall, of the Zehlendorf textile factory, with special reference to the solubilities of various natural and artificial cellulose products.

Other papers dealt with longitudinal swelling of cellulose and *Zellwollen*; relation between degree of swelling and textile properties; treatment of cellulose with formaldehyde and other substances with a view to the introduction into the molecule complex of foreign materials and to so-called bridge-building for controlled modification of properties; and various methods of testing both artificial and natural fibres. No new fibres were introduced, with the exception of a new acetate silk by Dr. A. Sippel, of the Rhodiaseta Works at Freiburg, for which remarkable strength is claimed.

WELFARE OF WAR-WORKERS AND SEAMEN

A REPORT issued by the Ministry of Labour and National Service on "Welfare Outside the Factory and Seamen's Welfare in Port" (Cmd. 6411) gives some account of the work of the Welfare Department of the Ministry, August 1941–August 1942 (London: H.M. Stationery Office, 2*d*. net).

In regard to the transference of war workers to various parts of Great Britain, a 'convoy' system under which, for example, women coming from Scotland to the Midlands meet at Edinburgh or Glasgow and are then brought down in a party overnight in specially reserved compartments, accompanied by officers of the Ministry, and are met at Birmingham by the reception officers, has proved extremely successful. In regard to lodging and billeting, the formation of local advisory committees, including representatives of the local authority, regional officers of the Ministry of Health and Ministry of Labour and National Service, the women's voluntary services and employers and trade unions promises to give good results in difficult areas. Reference is again made to shopping difficulties, to problems of travel to and from work, and to the care of transferred workers during sickness, all of which are receiving attention, as are problems of recreation, entertainment and holidays, while to free mothers for war work, special steps have been taken to see that their children are cared for during working hours.

In regard to seamen's welfare, the provision of hostels has been a major task of the Department and such hostels have already been provided at Liverpool, Cardiff, Newcastle and Hull, while others are being established at Leith and Glasgow. These Merchant Navy Houses are managed by the National Service Hostels Corporation. Recreational centres with facilities for meals and a drink have been established at Newport and Hull, and others are being established at Swansea and Avonmouth. Health questions are also receiving attention, and the hospitals now make known to the seamen's welfare officer the names of all merchant seamen who have been admitted, to facilitate visiting and the supply of books, periodicals, etc.

FORTHCOMING EVENTS

(*Meeting marked with an asterisk is open to the public.*)

Saturday, January 23

CHEMICAL SOCIETY (in the Chemistry Lecture Theatre, University College, Shakespeare Street, Nottingham), at 3 p.m.—Dr. R. A. Morton: "Vitamin-*A*".

Monday, January 25

ROYAL GEOGRAPHICAL SOCIETY (at Kensington Gore, London, S.W.7), at 5 p.m.—Mrs. Reginald Wyndham: "Java, Sumatra, Celebes, Flores and Bali" (Kodachrome and other films).

Tuesday, January 26

ROYAL ANTHROPOLOGICAL INSTITUTE (at 21 Bedford Square, London, W.C.1), at 1.30 p.m.—Dr. M. J. Field: "Some Aspects of Indirect Rule".

ROYAL INSTITUTION (at 21 Albemarle Street, London, W.1), at 3 p.m.—Sir Lawrence Bragg, F.R.S.: "The Solid State", (i) "Atomic Architecture".*

Wednesday, January 27

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, W.C.2), at 1.45 p.m.—Dr. E. S. Russell: "Trawling and the Stocks of Fish".

GEOLOGICAL SOCIETY OF LONDON (at Burlington House, Piccadilly, London, W.1), at 3 p.m.—Dr. K. S. Sandford: "The Geology of Northern French Africa".

Saturday, January 30—Sunday, January 31

ASSOCIATION OF SCIENTIFIC WORKERS (at Caxton Hall, Westminster, London, S.W.1). Conference on "Planning of Science, in War and in Peace" (to be opened by Sir Robert Watson-Watt, F.R.S.).

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

LECTURER IN PHYSICS AND MATHEMATICS at the Croydon Polytechnic—The Education Officer, Education Office, Katharine Street, Croydon (January 29).

LECTURER IN ELECTRICAL ENGINEERING at the Oxford Schools of Technology, Art and Commerce—The Chief Education Officer, City Education Office, 77 George Street, Oxford (February 6).

CHAIR OF MINING—The Secretary, The University, Edmund Street, Birmingham, 3 (March 1).

SENIOR PHYSICS MASTER—The Headmaster, Ellesmere College, Ellesmere, Shropshire.

ASSISTANT HORTICULTURAL OFFICER—The Chief Executive Officer, War Agricultural Executive Committee, The Deanery, Worcester.

TEACHER (MAN OR WOMAN) OF MATHEMATICS, PLUS PHYSICS AND/OR CHEMISTRY—The Headmaster, The School, Dartington Hall, Totnes, Devon.

LABORATORY STEWARD for the Sierra Leone Government Medical Department—The Secretary, Overseas Manpower Committee (Ref. 624), Ministry of Labour and National Service, Hanway House, Red Lion Square, London, W.C.1.

THE STATE OF HEALTH IN EUROPE

THE smoke-clouds of war which shroud the war zones and the absence of health reports and of foreign medical journals make it difficult to form a scientific appreciation of health conditions on the Continent of Europe. At the same time, references in the Press of Germany as well as of occupied and neutral countries, and information supplied by neutrals who have visited Germany and the occupied countries, supply us to some extent with accounts which enable a general impression to be formed. As regards nutrition, the countries which are in a desperate plight are Poland, Jugo-Slavia, Greece and occupied Russia. The 'hungry countries' are Belgium, France and Norway. Czechoslovakia is considered to be a little better off.

The Poles receive a diet of 800 calories a day, which is about one fourth of the German ration; the Jews in Poland have 400 calories a day, that is, half the Polish ration; this is insufficient to maintain adequate nutrition. In the 'hungry countries', on paper the ration card is adequate; but in practice the inhabitants frequently cannot obtain their full ration. This is due not so much to shortage of food-stuffs as to inadequacy of transport, and the fact that the peasants, especially in France, distrust the war currency and keep their produce instead of taking it to market. In France, rationing was introduced much too late, and at a time when stocks of food-stuffs were largely exhausted.

In all the occupied countries deficiency diseases are now to be found—rickets, spontaneous fractures of bone, beriberi and pellagra. There is a deficiency of calcium shown by the lack of calcification of teeth. New diseases are said to occur; for example, epidemics of nephritis have been reported. Pregnant women are inadequately nourished, and it is alleged that a second pregnancy is tantamount to maternal suicide. There is a high increase in infantile mortality.

Germany, as she has already announced, will be the last country to starve. Here the ration card can be taken at its face value. The Army is very well fed; the diet is sometimes monotonous alike in quality and quantity. The workers are well looked after, and up to recently coupons have always been honoured. There is believed to be a 'black market', although the penalties are very heavy. Infant mortality has not increased. The children receive special nutritional care and are given supplies of vitamin C. The supply of milk to expectant mothers and children is regular and good. These mothers also receive a preparation of vitamin D through the district nurses. Margarine has been enriched with vitamins. The Germans' chief trouble is the so-called 'fat gap'. To cope with this they treat bones in an autoclave in order to extract the marrow. They also experiment in the synthesis of fats. One method is to oxidize paraffin and then to combine it with synthetic glycerin. Blood sausages are made on a large scale.

Before the War the Germans imported a large supply of soya beans from Manchuria. This has not been a great success, as the stocks became rancid.

Tuberculosis is a well-known index of a people's health and nutrition. At the end of 1941 the death-rate from tuberculosis was greatly raised in the occupied countries, and it has also risen in Germany, as in the War of 1914–18. Tuberculosis seems rife in Belgium. Generally, the increase noted in the disease is ascribed to various causes such as the breakdown of preventive measures, the return of war prisoners to France with 'open' tuberculosis, migration and under-nutrition. The number of primary infections seems to be increased and, owing to the lack of fuel, the restricted dietary is used by the body tissues of patients in sanatoria mainly for thermogenesis and energy production instead of combating tuberculous lesions.

Summer diarrhœa is again prevalent in the occupied countries.

Little accurate information can be obtained concerning epidemics, though from time to time reference is made to such outbreaks in the foreign Press. Recently it was stated that a severe epidemic of scarlet fever was raging in Denmark. In eastern Poland a virulent outbreak of tularæmia has been reported. This disease was previously unknown in Poland and seems to have been introduced from the U.S.S.R.

The chief epidemic bugbear is typhus. In Rumania there is little or no typhus, and the situation there appears to be well in hand. Polish prisoners of war, who might have conveyed the disease, were removed from the malarious area in the bend of the Danube to a healthier district, on public health grounds. Since the War, there has been much typhus in Poland, especially in the western region. In Warsaw and the Warsaw district there were some four thousand cases in 1940 as against thirty-three in 1938. There has been some typhus among German troops and in the front line. How much typhus has occurred in Germany it is impossible to say because the German figures do not include troops or residents in refugee camps. There has been no typhus in Hungary. Eighty-five cases are noted as occurring in a prison at Marseilles. The disease was imported from North Africa.

Every German soldier is inoculated with an omnibus vaccine in one administration. This contains an attenuated vaccine against typhus, an anti-typhoid vaccine (polyvalent) and a vaccine against dysentery. The inclusion of the latter vaccine seems of doubtful value. On the Continent a dead vaccine against typhus is chiefly used. The Germans are largely employing a brand prepared at the Pasteur Institute, Paris. There is a shortage of drugs, especially as regards anæsthetics, morphia and quinine.

The Allied Governments have announced that their first charge after the War will be to feed the inhabitants of the occupied countries, and they are making plans for this responsibility. If these countries are liberated gradually the task, obviously, will be much easier than if Germany collapses suddenly, as in 1918. A Continental expert considers that the chief demands will be for proteins, carbohydrates, yeast and ascorbic acid. The food should be supplied in as concentrated a form as possible in order to feed the greatest number. At first it will not be necessary to aim at an ideally balanced diet. Energy-providing foods will be the main requirement.

GEOLOGY, GEOLOGISTS AND THE WAR EFFORT

On various occasions apprehension has been expressed by British geologists at the haphazard use of them and of their science in the prosecution of the War. For example, the general unawareness of the services which geologists are able to render was dealt with by Prof. P. G. H. Boswell in his presidential address to the Geological Society in 1941. Later, Prof. H. H. Read discussed the position in an article in NATURE of January 10, 1942, and he has recently returned to the same topic in a talk, referred to below, to the Parliamentary and Scientific Committee. Further, in NATURE of March 14, 1942, the role of geologists in war-time was considered in a leading article, the concluding sentence of which was: "There must be more enlightened direction from above, to ensure that wherever geology impinges on human activity, in war or in peace, the contribution it can make is recognized without delay and appropriate action taken".

This advice, wherever else it may have borne fruit, appears to have fallen on stony ground, if we are to believe a Press report, at a "northern school of military engineers", where it is stated that a squad of water-diviners has been formed in the Royal Engineers. The information has most likely aroused nothing but a little pleasurable excitement among the general public who, as Prof. Boswell and Prof. Read both emphasized, are deplorably ignorant of geological matters. Unfortunately, however, this interesting item of British news was reproduced in the *New York Times* under the caption "Dowser Squad in Army—British to use Water-Divine s in the Middle East". Certain of the Americans, like most of the Russians, are more aware of the part to be played by geological knowledge in war, and this small news item will not tend to increase their estimate of British military efficiency.

The present position was summed up in a revealing reply given by Sir J. Grigg in the House of Commons on January 19, in answer to a question by Capt. Studholme as to what extent the War Office relies upon dowsers for advice on water supply. The reply is worth quoting in full: "The War Office does not rely on dowsers for advice on water supply in the United Kingdom, and so far as I know the only place where they have been tried is the Middle East. A report of their performance there showed a very small percentage of successes, and orders were issued that scientific geological methods only were to be used."

Total war implies the use of any and every means to beat the enemy. There are circumstances in which the employment of a squad of dowsers would be justifiable and proper to this end. Those circumstances would arise when no geologists were available or no geological information obtainable. Then in that dire hour, water-divining, witchcraft, magic or necromancy of any hue might be called upon both 'to amuse the troops' and to lend a degree of colourful camouflage to plain 'wild-catting'.

But these circumstances justifying the use of dowsers do not exist, for both geologists and geological information are in plentiful supply. It is known that a number of geologists are serving in many branches of the army, but not as geologists; among the members of the Canadian forces in Great Britain are geologists of experience, resource and skill. The staff of H.M. Geological Survey of Great Britain includes geologists completely conversant with every aspect of underground water-supply; many academic and professional geologists are available with a skill in the investigation of groundwater problems acquired in many years of consulting practice. A galaxy of geological talent is thus ready and eager to apply the resources of their science. We have, however, to record the melancholy fact that, so far as we know, two geologists are employed as such in the British Army. During the War of 1914–18, the number of geologists employed as such in the Forces was, by slow and painful steps, raised to five; the recent formation of the 'Dowser Squad' appears to indicate that there is still little appreciation in military circles of the services geologists can perform.

It is probable that these remarks will incite the wrath of water-diviners. It must here be explained that this present protest is more concerned with the non-employment of geologists, who are demonstrably equipped for the investigation of underground water, than with the employment of water-diviners, who are not demonstrably equipped with any certain powers in this direction. In this latter connexion, it is worth while to recall the tests of dowsers made at Guildford some thirty years ago. These tests are recorded in the *Sanitary Record and Municipal Engineering* of May 2, 1913, and were conducted by a committee of scientific men with the late William Whitaker, F.R.S., as chairman. Whitaker had no rival in his knowledge of the groundwater of south-east England. Three sites were chosen which gave a variety of known underground water conditions. One site had 20 ft. of gravel on clay and was traversed by a large sewer, the second formed the top of a service reservoir from which water was rapidly being run off, and the third was known to contain a hidden spring with a yield of about 50,000 gallons an hour. These conditions afforded an ideal test for water-diviners. Seven diviners were conducted over the sites and their findings recorded and compared. The descriptions of these would require too much space, but the conclusions of the Committee may be given. They are as follow:

"The general conclusions of the Committee on comparing the state of facts known to exist with the indications given by the diviners, are that whatever sensitiveness to underground water may exist in certain persons, of which some evidence has been given, it is not sufficiently definite and trustworthy to be of much practical value. Moreover, the lack of agreement with each other shows that it is more a matter of personal mentality than any direct influence of the water. The diviners as a rule confine their attention to small streams of water, and as there are few places where these cannot be found they may well show a large percentage of successes."

On the most charitable judgment, therefore, the powers of water-diviners are 'not proven'; on an ordinary judgment, they are "not . . . of much practical value". The formation of the 'Dowser Squad' of the Royal Engineers is an event which cannot commend itself to the scientific public. It is an event, too, which becomes inexplicable when it is recalled that an account of the uses of geology during the last War was published by the Royal Engineers themselves in a volume entitled "The Work of the Royal Engineers in the European War of 1914–1919: Geological Work on the Western Front" (Chatham: Secretary, Institution of Royal Engineers, 1922).

In the talk* to the Parliamentary and Scientific Committee to which reference has been made, Prof. Read makes a number of representations, among which is one inviting that Committee to press upon the War Office and other Service Departments the importance of the contributions that geology can make to the war effort. Prof. Read quotes Sidney Paige, senior geologist in the North Atlantic Division, U.S. Engineers, as saying: "Let thought be directed toward methods of supplying all possible relevant technical data, geological and otherwise, to those who have a particular engineering job to perform in the Army or out of it".

One of the difficulties in carrying out this sound advice is that unfortunately geologists alone appear to be qualified to decide the type of work for which geology is required. This restriction results fundamentally from the neglect of geological studies in the schools and universities, a neglect which forms the subject of another of Prof. Read's representations.

This difficulty just mentioned—that geologists know best when they should be employed—is among the topics considered by F. L. Aurin in a "Memorandum to Members of the National Service Committee of the American Association of Petroleum Geologists"†. In this memorandum, it is pointed out that engineering skill cannot be substituted for the geologist's knowledge of rocks. Aurin maintains that this has been repeatedly demonstrated in the United States and cites the case of the present road between Los Angeles and the San Joaquin Valley; the present route was indicated as the most feasible one by geologists about fifteen years ago, but for many years competent engineers struggled with construction and maintenance problems on an alternative route. He asserts that geologists should have worked ahead of the construction parties on the Alaskan Highway, and that geologists should be on other critical military roads such as any from India to China. Aurin's memorandum contains the following pertinent paragraphs:

---

* Geology and Geologists in the War and the Peace. By Prof. H. H. Read. (Parliamentary and Scientific Committee, Courtfield House, London, S.W.7.)

† *Bull. Amer. Assoc. Petroleum Geol.*, 26, No. 7; July 1942.

> "Since the type of work to which geological skill will contribute can be determined only by a geologist, it is essential that there should be an organization in the Army comparable to that used in industry. No industrialist of experience would dream of attempting to make the decision of whether or not geologic work is desirable on a given project. He, therefore, establishes a chief geologist with adequate staff to advise him when and where and what type of work should be done and to recruit the essential personnel and assign it to its tasks. There should, therefore, be such a staff geologist so located that he will automatically learn of contemplated construction projects and of the areas where knowledge of the geology will contribute to the effectiveness of attack or defense. These men will then be able to advise that a certain number of geologists with certain qualifications are needed at this, or the other point."
>
> "Without some such mechanism as has been outlined, I see no hope that geology can be used as one of our special tools for winning the war. If such mechanism is provided, I have no doubt that it will contribute very substantially and that each geologist so employed will save men and materials for other effort and will, in special cases, contribute as only a highly trained specialist can contribute to our success."
>
> "In this war, as in no preceding war, we depend on science, and geology is a specialized branch of science for which there is no substitute."

It appears from this memorandum that the United States, in spite of its much better geological record, than that of Great Britain in the War of 1914–18 and of its considerable awareness of the importance of geology, still has not reached perfection in these matters.

The utilization of geology and other branches of scientific knowledge was the topic of the discussion which followed Prof. Read's talk, to which notes by various speakers are appended. There, for example, Mr. J. G. Bennett, of the British Coal Utilisation Research Association, considers that the technical information already available from the coal survey of Great Britain is not being exploited to the fullest possible extent. Dr. N. F. M. Henry regards geologists as themselves largely to blame since they have neglected to take active steps to ensure that geological knowledge is properly applied. More fundamentally, Mr. G. B. R. Pimm, of the Institution of Structural Engineers, considers the utilization of science and scientific workers by the Service Departments as part of a much larger question, namely, their proper use in the War, and the reconstruction and post-war periods. Mr. Pimm considers that this "can only be brought about by Regulations introduced by Organised Science, defining the place of Science in the service of the community, and the status, and rights and duties of all scientific bodies, particularly the Chartered Bodies already charged with the advancement of the various branches of Science".

These are broad and large matters following upon the consideration of the place of dowsers in the war effort, but the mobilization of the small 'Dowser Squad' is a symptom of a widespread disease.

J. J. THOMSON

The Life of Sir J. J. Thomson, O.M., sometime Master of Trinity College, Cambridge

By Lord Rayleigh. Pp. x+300+8 plates. (Cambridge: At the University Press, 1942.) 18*s*. net.

LORD RAYLEIGH has written a most excellent and satisfying account of the life of Sir Joseph Thomson. The book gives an adequate explanation of Thomson's epoch-making scientific work, and, in addition, a sympathetic and revealing description of his characteristics as a man.

Modern physical science is not an easy subject to expound to those who have no background of scientific knowledge. A choice has to be made between using elementary mathematics, and eschewing even the simplest equation in favour of a sometimes long circumlocution in words. In the preface, Lord Rayleigh makes it clear that he has chosen the latter course—"No formulæ have been used". Even so, eminent literary men have been heard to say they could not follow the scientific part of the book. Whether this is due to the difficulty of the author's task or to the deficiencies of a literary education must remain a matter of opinion.

Within the limits Lord Rayleigh lays down for himself, Thomson's work is well described, due emphasis being given to the more important results. The new physics may be said to have begun with Röntgen's discovery of the X-rays in 1895. The rays were found to make gases conductors of electricity, and Thomson and Rutherford carried out a joint investigation which showed that conducting particles are produced by the X-rays and that the particles can be made to carry a current if acted on by an electric force. By this process the charged particles are removed, as indeed they are if the conducting gas is left to itself. Thus there are likenesses and differences between conduction through gases and through liquids; both are due to the motion of charged particles or ions, but in conducting liquids the ions are always present, while in gases they have to be formed continually by an ionizing agency. On these lines an explanation of the phenomena of conduction through gases was given.

Thomson then turned to a study of cathode rays—the straight rays which proceed from the negative electrode when a current is passed through a gas at low pressure. Two views of their nature were held: most English physicists, following an original suggestion of Varley, thought that they consisted of a flight of negatively electrified particles, while a theory of waves was supported in Germany. The rays are deflected by a magnetic field, and, at an early date, Thomson, chiefly for this reason, took the corpuscular view. He measured the deflexion caused by a known magnetic field, and the kinetic energy of the rays by a thermo-couple, and thus found that the velocity was 15,000 km. a second and the ratio of mass to charge was 2×10^{-8} gm. per coulomb, to compare with 10^{-5} for the hydrogen ions in liquids, about a thousand times greater; thus in cathode rays either the charge must be larger or the mass smaller. In 1897 Thomson made the cautious statement: "these numbers seem to favour the hypothesis that the carriers of the charges are smaller than hydrogen atoms"—a momentous pronouncement which does not seem to have created much interest at the time; the chemical atom was too firmly established. Then he attacked the problem in another way. If the cathode ray stream consists of negative particles, it should be deflected by an electric field. Thomson therefore passed it between two parallel metal plates connected with the opposite poles of a battery, and, when the residual gas was very highly exhausted, got the deflexion. From this, he found a ratio of mass to charge agreeing approximately with his former result.

Much evidence was available to show that electricity, like matter, is atomic, the unit being that carried by the hydrogen ion in electrolysis. It was therefore increasingly probable that in cathode rays the mass was small, not the charge large. To confirm this result it was necessary to measure the charge directly, and this was accomplished by Thomson using a method based on the rate of fall of cloud drops condensed on gaseous ions, a method developed from work of C. T. R. Wilson and used by J. S. E. Townsend, who confirmed thereby that the charges were the same as those on liquid hydrogen ions. On these results, combined with Rutherford's on ionic velocity, Thomson found the charge on a single particle to be 2×10^{-19} coulomb, which confirmed the conclusion that the mass was much smaller than the hydrogen atom. Again, in order to measure both quantities on the same particles, Thomson used those projected from a metal plate exposed to ultra-violet light in a gas at very low pressure. The same result followed.

These infra-atomic particles were at first called corpuscles by Thomson, but they were soon identified with the electric units named electrons by Johnstone Stoney, a name also used by Larmor, Lorentz and others. After some years, Thomson himself adopted what had become the general usage.

This amazing discovery was J. J. Thomson's greatest contribution to physical science ; others had been working towards the result, but the chief credit goes to Thomson. His investigations opened a new epoch and led to the enormous developments of the last forty years.

Rayleigh points out that, after a comparatively quiescent period during 1901–6, Thomson gradually reached another peak, culminating, about 1912, with his work on positive rays, a fitting counterpart to his investigation on cathode or negative rays. Positive rays are much less easily deflected than negative ones, and are clearly ordinary atoms or molecules carrying electric charges. If the electrostatic and magnetic deflexions are arranged to be at right angles to each other, since one is inversely as the velocity and the other inversely as its square, a parabola is traced on a photographic plate, and if other charged atoms or molecules are present, each one produces its own parabola. For this work high vacua are needed, and the success was largely due to Dewar's method of absorption in charcoal cooled in liquid air. Thomson's most striking result was the discovery of two curves for the gas neon, indicating atomic weights of 20 and 22. Thus ordinary neon is a mixture of two bodies, named by Soddy isotopes. This discovery pointed the way to the great work of F. W. Aston, whereby so many elements have been shown to consist of isotopes.

Thomson was a great experimentalist, but he was not a skilful manipulator. He depended on others —especially his assistant, Everett—to handle his apparatus, though he was fertile in planning, and in suggestions when difficulties arose.

Science, moreover, owes to Thomson the creation of the Cavendish school of physics. When Cambridge in 1895 admitted as research students men from other universities, they flocked to the Cavendish Laboratory in ever-increasing numbers. Most of the prominent physicists in Great Britain and the Dominions, and many in the United States, received part or all of their training at Cambridge. Thomson's relations with the research students were most happy, and perhaps best seen at the annual Cavendish dinner, with songs composed for the occasion. Rayleigh singles out for special commendation one of which the chorus runs :

> "Here's a health to Professor J. J. !
> May he hunt ions for many a day,
> And take observations,
> And work out equations,
> And find the relations
> Which forces obey."

Lord Rayleigh justly praises also Thomson's moderately elementary lectures meant for undergraduates reading for Part I of the Natural Sciences Tripos. Rayleigh says, "I think I learnt more from these lectures than from any others I ever attended". Perhaps I may be allowed to echo those words.

From 1915 until 1920 Thomson was president of the Royal Society. For the first three years of the period the Society and many of its members were engaged on war work. Thomson himself served on the Board of Invention and Research under the chairmanship of Lord Fisher, for whom he acquired a great admiration.

In 1918 Thomson became Master of Trinity College. The appointment is in the gift of the Crown, and the Prime Minister (Mr. Lloyd George), after consulting Lord Balfour, recommended J. J. Thomson, knowing, he says in a letter to Lord Rayleigh, "his supereminence as a scientist". In his new post Thomson had to face duties and responsibilities unlike those to which he was accustomed. But his devotion to the welfare of the College, his interest in both its intellectual and its athletic achievements, were soon patent to all and won the appreciation of both fellows and undergraduates. As Lord Rayleigh says, he was readily accessible, never in a hurry, and always good-tempered, sometimes in rather trying situations.

Thomson died on August 30, 1940, and his ashes were laid in Westminster Abbey, near the graves of Newton, Darwin, Herschel, Kelvin and Rutherford.

Lord Rayleigh's book gives a worthy account of a great man of science. W. C. D. DAMPIER.

ATLANTIS REVISITED

An Unknown Land

By Viscount Samuel. Pp. 222. (London : George Allen and Unwin, Ltd., 1942.) 12*s*. 6*d*. net.

IT is no difficult task for a philosopher with some knowledge of science and some ideas for the regeneration of the human race to paint a picture of Utopia. What is difficult is to portray a Utopia in which the ordinary man or woman would care to live. Possibly W. S. Gilbert's gentle irony has all but achieved that feat, and suggestive as are many of the passages in this entertaining book, with one reservation, it is not the fascinating picture of scientific advance and social and intellectual development that remains most clearly in the memory after reading this book, but rather those passages in which, describing three of the States of the "Small Heads" who have separated in schism from the Utopia of the "Big Heads", Lord Samuel gently satirizes Russia, Germany and Great Britain. A competent journalist with real knowledge of science might have given as suggestive an account of the scientific advances of the Bensals, their achievements in agriculture, in industry, in fishery, in atomic energy, but in this long chapter on the Islands there is humour and humanity, and the philosophy which is the distinctive feature of Lord Samuel's essay in Utopia is warm as well as prescient.

Lord Samuel uses an old device to let his imagination and philosophic mind depict a people of reason and peace, detached from this disordered world, in the Southern Pacific where Bacon placed his "New Atlantis". Of Bacon's work this is indeed a continuation, though Salomon's House is no longer the one organization for scientific research as described by Bacon. It has been split up into several establishments in different places, though the Renfusa Institute at the capital town of that name is the lineal descendant of Salomon's House, and its central buildings on the same site are devoted to physics, astronomy and inorganic chemistry, with some of their applications in engineering and chemical industry. Biology has been transferred to an immense Institute elsewhere, and if neither biologists, physicists nor chemists can be expected to take Lord Samuel's account of Bensal achievements in research too seriously, that account should not be altogether rejected.

The chief defect of the book is indeed that Lord Samuel has poured too much detail into this receptacle of his full and inquiring mind. That may well obscure one of the dominant features of the book in contrast with Bacon's "New Atlantis". It is an essay on the reconciliation of philosophy, science and religion. With the new era which opened in Bensala with the introduction of suturization, the operation by which the Bensals delay the closing of the sutures of the skull and so give a longer period for the development of the brain, the inhabitants of Lord Samuel's Utopia turned from their concentration on material progress, with its achievements in mechanical invention, industrial chemistry and agricultural biology, to philosophy and religion. Here Lord Samuel develops not only a theory of education and a profound philosophy of "mental ambiency" but also the ideas of the 'sieve' into which the Bensals put all the ideas of the past and from which they extract the sensible "gist"—a kind of Napoleonic code of all knowledge and faith which assists the mind to discard its lumber.

Lord Samuel writes with his own charm and distinction, but does not disguise his debt to Butler and to Wells, no less than to Bacon. None the less, there is a certain unreality in this philosophical and ethical discussion. In banishing squalor and wretchedness and misfortune, the Bensals have banished also the human greatness of spirit which can triumph over tragedy and misfortune. The smug complacency of the Bensals is at times in almost revolting contrast with the heroism and fortitude with which thousands of men and women to-day are facing the tragedies and hardship of this War. It is difficult to believe that Lord Samuel anywhere in this volume touches the ultimate issues and values of human experience.

On a more practical plane, the pertinence of Lord Samuel's picture to present discussions on reconstruction is clear. By the device of inviting the Bensals to suggest the first steps to be taken if we were to accept as an ideal a system more or less like their own, he outlines a practical programme of reform. Also he delineates firmly and with prescience the problems that advancing mechanization and increasing leisure must set for us too, and on the road to reconstruction he sets the lights unmistakably at amber and green.

The contrast between the Bensal working week of nine hours, their custom of primary and secondary occupations, their elimination of purposeless occupations, may be in exaggerated contrast with conditions in Britain. That exaggeration, however, effectively points to the constructive thinking that must be done on the problem of leisure and on education for citizenship, before we can enjoy the advantages which mechanical advance has put in our hands without social disruption or disorganization in mass unemployment and mechanized amusement. This compressed mixture of science and philosophy, religion, politics and economics is not too indigestible to stimulate thought as to where mankind is going, and the moral values as well as the material standards which should be our guide. It may well have its place in provoking that new outlook and the receptive and creative minds through which alone there can emerge after this conflict a world order, warm with human life, safeguarded with humour, as well as enriched by the wise, ordered and co-operative use alike of the traditions and experience of the past and of the powers which science has put into our hands.

R. BRIGHTMAN.

BRITISH BIRDS

The Birds of Britain

By James Fisher. (Britain in Pictures Series.) Pp. 48+12 plates. (London and Glasgow: Wm. Collins, Sons and Co., Ltd., 1942.) 3*s*. 6*d*.

MR. FISHER'S "Birds of Britain" belongs to a series, Britain in Pictures, the distinctive features of which are (1) the beautiful illustrations, generally from work by leading artists; (2) the high standing of each author in the subject about which he writes. The book before us is no exception. Mr. Fisher is one of Britain's best young ornithologists. The illustrations in his new book have been chosen from the works of the best British artists and are represented by twelve coloured plates, beautifully reproduced, and twenty-six black and white drawings.

The author includes 424 different species of British birds, a list which is complete up to 1941. These are very usefully divided into nine sections: (1) residents (133); (2) residents now extinct (1); (3) summer visitors which breed in Britain (52); (4) summer visitors which have bred in the south (2); (5) winter visitors (26); (6) passage migrants (23); (7) scarce or irregular visitors, and vagrants (100); (8) birds which have been reliably recorded in Britain a dozen times or less, but more than once (61); (9) birds which have been reliably recorded only once in the British Isles (26). In his review, Mr. Fisher does not give a long list of the birds with descriptions useful only for reference purposes; most of his text makes fascinating reading. It is divided into sections: a bird's-eye view of Britain; peculiarity of British birds; historical changes; late changes; the observers; the future.

This book will prove to be a valuable acquisition to anyone interested in natural history.

THE NATIONAL GALLERY IN WAR-TIME

By F. IAN G. RAWLINS
Scientific Adviser to the Trustees

IT is one of the necessary sorrows of war that scientific workers are bound, for the most part, to apply their knowledge and skill for the time being to the work of destruction. It is also true, as is already obvious, that some good comes out of evil, but the primary aim is, and must be, to destroy. Naturally, there are heroic efforts to mend and to repair, perhaps even to restore; yet they are hard pressed to keep pace with the forces of obliteration. In this article, however, we are contemplating a happier theme, in which applied physics and kindred branches of technics have been harnessed deliberately and specifically to a project of conservation. Consideration of some such scheme is usually simplified a little by financial reasoning—the relative value of the things to be kept safe and the cost of doing so. But with the nation's heritage of pictures, in some respects the most precious and representative in the world, these terms become largely meaningless. It is the bare fact of irreplaceability which dominates thought. Loss or serious damage admits of no compensation. If science can help in this great quest for security, it will have shown that even in war its part is not wholly to undo. To save for posterity becomes an overwhelming urge.

Well before the outbreak of hostilities, the Board of Trustees of the National Gallery had approved plans for evacuation from the great building in Trafalgar Square, London. These were, in fact, implemented and the bulk of the collection was hundreds of miles away from London immediately before September 3, 1939. The programme of removal had been accomplished in ten days, in accordance with schedule. A tolerable exile had been arranged in various houses and halls. So far so good. Risks were reasonably spread. Administration and invigilation functioned duly. But was all this sufficient? Indiscriminate bombing all over Great Britain set in. Nowhere above ground was safe in the special sense applicable to unique and irreplaceable objects. Even the fire-risk assumed new proportions in some respects. Thus, inevitably, the question was raised whether deep shelter could not be found, and if it could, what new hazards and imponderables it would introduce. Here indeed was a task for science, to shoulder its full measure of responsibility. In the sequel, some indication may be seen of the course of events. Meanwhile, all the refuges above ground had fulfilled their purpose, providing safe shelter unimpaired until their supersession.

A Deep Shelter Policy

In a matter of days, as it turned out, the Gallery was committed in principle to seek a subterranean home. The prime need was to find it. Mines, quarries, tunnels, caves, even deep defiles capable of being artificially roofed and reinforced were visited and discussed. Seldom must such a search have been started, and more rarely still could one have been more disappointing in its opening stages. Site after site was rejected on grounds such as those of possible flooding, presence of noxious vapours, insecure roofs, difficult access, probability of becoming a target later on for indirect reasons, and so forth. Up to the time of writing, two of these locations are definitely known to have experienced incidents which, had they happened when in use as repositories, would have constituted in one case a major disaster, and in the other a potential threat too grave to have been disregarded. These facts are mentioned to demonstrate that sanctuary was not to be had merely for the asking.

Six precious weeks went by with nothing to show for them but negation. Then, almost by chance, the outlook changed. A site offering sufficient space to house the whole collection, and possessing between 200 ft. and 300 ft. of rock cover, appeared. The access was not easy, and it was obvious at once that fairly heavy works would be needed to make it suitable for the purpose. Nevertheless, it was possible. The natural temperature within was 47° F. and the relative humidity 95–100 per cent. Tradition locally had it that the temperature was unchanged throughout the year. No data in support of this were extant, and there was no time to begin extended observations. Instruments were put in position for a week as a rough guide. The temperature remained at 47°–48° F. and the relative humidity at a point approaching saturation. There was no alternative but to accept these figures as characteristic. A good record for freedom from falls of roof was produced (for this particular type of workings), and the risk of flooding could be taken as negligible. There were no noxious vapours, and the material present in bulk was chemically inert. There were other features too, not shared by most places of the kind, of a favourable nature. Beyond these broad considerations, nothing could be said with certainty. In addition to the increasing danger to the pictures in their quarters above ground, it became necessary for special reasons to make an immediate decision to accept or reject this place. In any event, some six to twelve months would elapse before it could be ready for occupation.

Within a matter of days, the Trustees, the Treasury and the Office of Works (now the Ministry of Works and Planning) had agreed to accept and to go ahead. It amounted almost to a venture of faith. The National Gallery thus became possessed of a repository offering cover against aerial attack to a degree approaching impregnability. Nothing but an earthquake could harm the contents mechanically. At the same time, due to the high relative humidity, ruin within a month might be expected for the pictures if this was not dealt with, and restrained, during the whole period of occupation. Furthermore, access was physically impossible for a large percentage of the collection. Thus, to begin with, matters were not easy. But the decision was clear-cut. The protective cover was ample, and the capacity for storage adequate. All the other troubles must in consequence be overcome.

Reviewing the situation at the present time, with the great collection safely housed, it may be stated that no major disadvantage was overlooked in that rapid decision. It was thought to be feasible to accomplish the task, and so in the event it has proved. Naturally, this is far from implying that there is little more to do. Life there, in some respects, resembles that of the crew of a ship at sea. Constant watch and ward was never more essential. There is much machinery, and full provision for emergencies. The pictures themselves need thorough-going inspec-

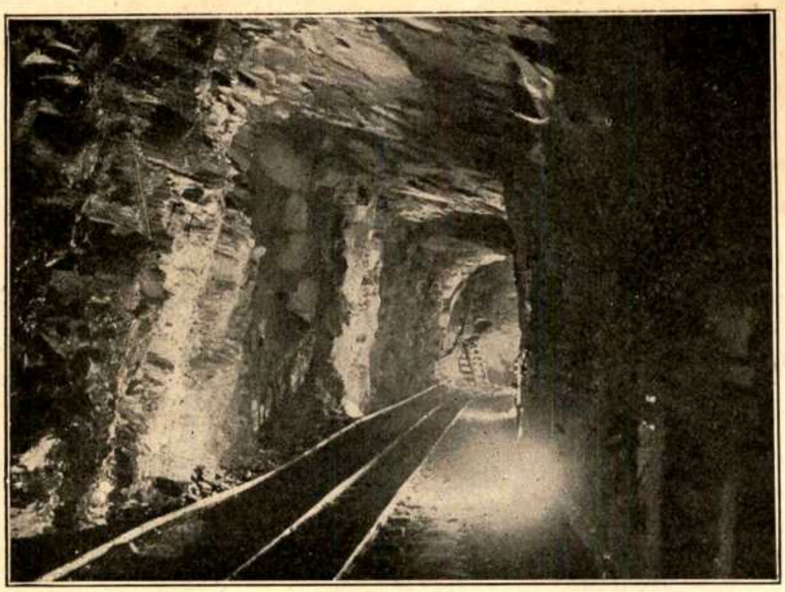

Fig. 1. THE MAIN UNDERGROUND APPROACH LEVEL. THIS WAS ORIGINALLY OF CROSS-SECTION 6 FT. × 6 FT. AND WAS ENLARGED TO 13 FT. 6 IN. HIGH AND 10 FT. WIDE.

tion at frequent intervals, if one is to be reasonably certain that all is well. Sometimes they need treatment, and this has been provided for. Temperatures, relative humidity, ventilation, electrical gear, the stability of the fabric, the workings themselves, all require ceaseless attention if accidents are to be avoided to within the limits of human fallibility. There is plenty of the unknown in this great bid for safety. From the beginning, the main responsibility for the safe-keeping and administration of the National Collection in exile has rested upon Mr. Martin Davies, to whom also is due much of the planning of its underground home.

In the next section, the arrangement of the repository and the apparatus installed will be described in some detail. Where information is lacking, the explanation is probably that data on that particular matter exist, but must be withheld at present for security reasons. When the time is appropriate more can doubtless be said.

The Underground Repository

The decision to place the great national collection below ground having been taken, the work of making the site suitable for the purpose devolved upon the (present) Ministry of Works and Planning. At this point a tribute of appreciation to the officers and staff of that department may be gratefully made, both for what has been done and for the way in which they have striven to meet the special requirements and ideas of the National Gallery. With a project so novel, it was only to be expected that some set-backs would occur; the isolated position and the season of the year in which operations began both had their share in making progress exceptionally difficult and arduous. When the full story of this aspect can be told in detail, it will probably be admitted that the period of preparation, though somewhat longer than anticipated, was not excessive. The managing director of the company working the site did all in his power to help in every way. The site was first seen on September 17, 1940. Four days later the decision to accept it was taken. Blasting operations started a few weeks later, and most of the buildings were ready for drying-out (but not for occupation) in May, 1941. By August, 1941, all essential engineering services had been completed and the buildings were ready to receive the pictures. The move in began on August 12, 1941.

The nature of the underground workings was such that the only reasonable way of securing proper temperature and humidity conditions (as well as due invigilation) was to erect separate buildings underground, and to 'condition' them individually. (By 'condition' is not meant full air-conditioning, as technically understood, but bringing physical conditions within each building to a state satisfactory for the contents, by the comparatively simple means to be described later.)

These buildings were designed to have no mechanical strength; they are simply 'envelopes' on a large scale. Of light brick construction and the inner walls and ceilings covered with wall-board, the floors are concrete, and the roofs are of fabricated material (treated with ruberoid) on top of which rests a wire-mesh mattress. The function of this is to distribute the weight, should any *small* fragments of rock fall from above. No provision is made against *heavy* falls of rock. This matter is one for constant expert vigilance on its own account, and upon it complete reliance

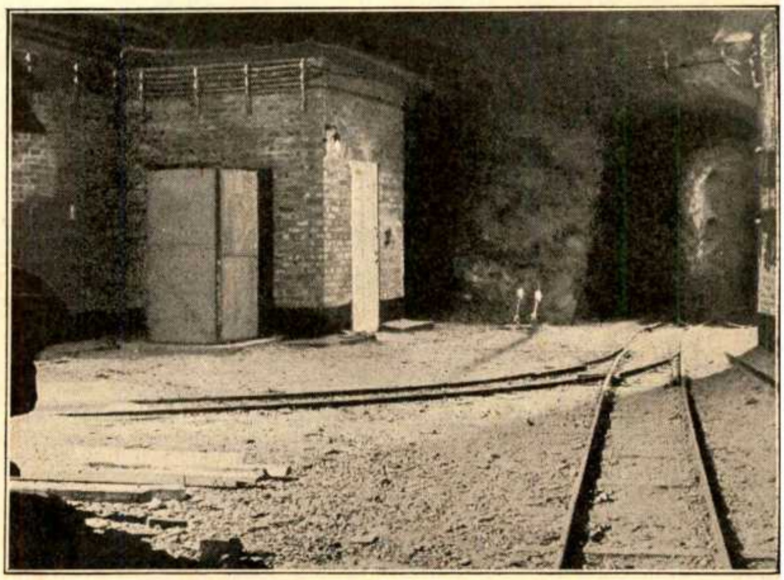

Fig. 2. A TYPICAL PLANT ROOM AND PART OF STORAGE BUILDING.

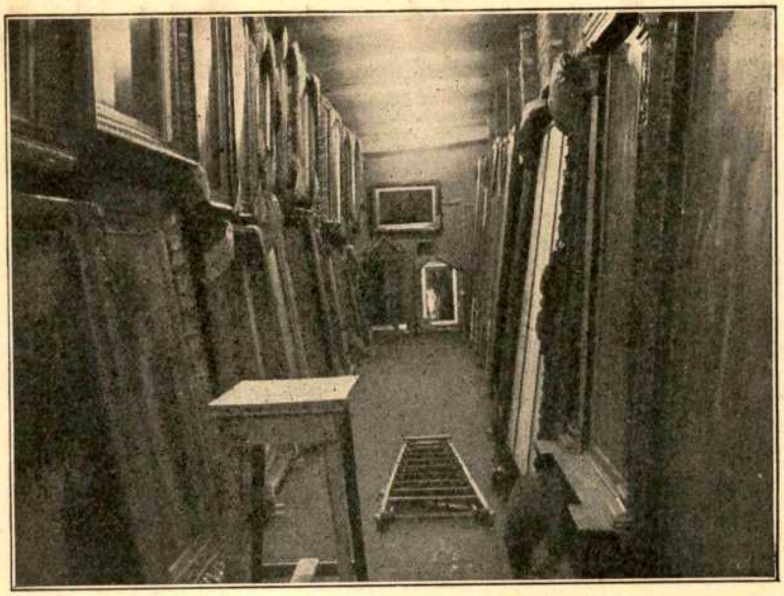

Fig. 4. INSIDE ONE OF THE STORAGE BUILDINGS, SHOWING PART OF AN AISLE, WITH PICTURES IN POSITION. THE HEIGHT IS 10 FT. FROM FLOOR TO CEILING.

has always been placed. Steps have been taken to ensure that all aspects of this possible hazard are kept under close review.

A question to be decided at the outset, which had a direct bearing upon lay-out, was the amount of wall-space needed, regarded particularly as a function of height. The guiding principle was that, in general, stacking of pictures was to be avoided. All were to be accessible for ready inspection. In this way, the problem was one of two dimensions rather than of three. The demand for height was such that ten feet would suffice for the great bulk of the collection, with fifteen feet for a small percentage of the total. In fine, this meant six buildings, five giving a headroom of 10 ft. inside, and one with a 15 ft. clearance.

These needs made somewhat rigorous demands upon the placing of the buildings, if maximum accommodation was to be secured. Thus, they vary considerably in shape and size. All except one are on a common level; the exception is approached by an easy flight of steps, and is reserved for pictures capable of being safely carried up by hand. Fortunately, there are many of a size suitable for this. The question was discussed at the outset whether any real advantage would be gained by having two-story chambers, where the natural height available permitted. This was answered negatively, both on the score of time and expense of making such buildings, and of the difficulty and dangers of taking pictures to and from the upper floor by stairs, lifts or cranes.

It may be mentioned here that the 15-ft. chamber already alluded to was designed to serve a double purpose. Its first duty was to act as the receiving and unpacking station. The vehicles containing the pictures, when they arrived, drove down a tunnel some 200 yd. in length, into this building, which is large enough to allow of turning and is provided with a suitable unloading dock and ramp. In fact, this building was planned in close co-operation with the railway companies who undertook the task of transport. The second purpose of the building was to house the largest pictures, and to act in some measure as an inspection shop for all the larger works. Thus, all unpacking took place in 'conditioned' surroundings. The overall size is solely governed by the amount of space available, but the inside dimensions were most carefully considered in the light of general experience in moving, storing, and inspecting pictures. A fair amount of room is needed for carrying, turning and so forth: to cramp this unduly would be to risk accidents. Almost every building is provided with a small work-room where such operations as laying blisters can be carried out. By these means it is rare that a picture has to leave its conditioned surroundings for treatment.

The plant-room contains the heating and ventilating machinery required for each building. One such plant-room and equipment suffices for each, except in two instances where shape and capacity necessitated the provision of two such plant-rooms.

The guiding principle in regard to the major problem of 'conditioning'—in the limited sense already explained—has been to make each building a separate self-contained unit which can be controlled individually as desired, so far as temperature and relative humidity are concerned. The advantages of this were found in the early stages of occupation, when the storages were gradually filling up with pictures (after a suitable

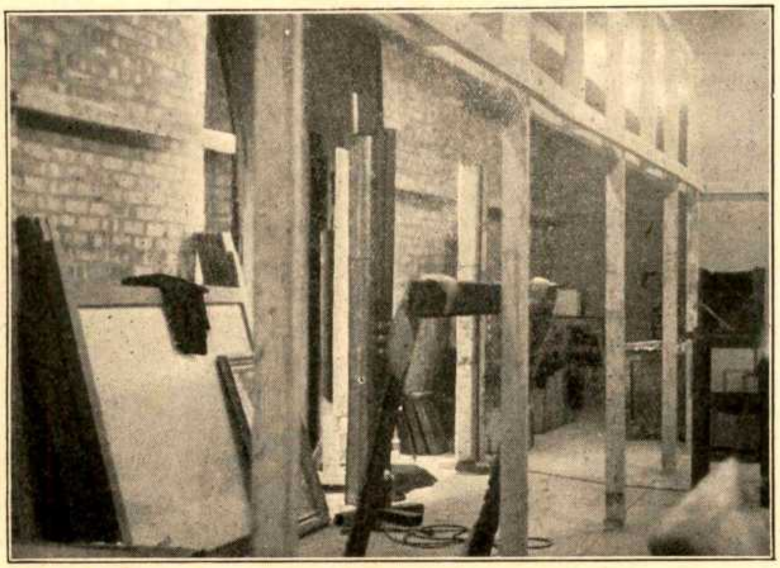

Fig. 3. PART OF A STORAGE CHAMBER BEFORE OCCUPATION, SHOWING STACK OF SCREENS (LEFT), READY TO BE FIXED BETWEEN THE UPRIGHTS IN CENTRE.

period of thorough drying-out, expedited by the use of refrigerating plant). Due to the concentration of so much hygroscopic material (wood and canvas), it is easier to obtain stable conditions when a building is full than when it is empty. In addition, certain other categories of valuable material are present, which need a physical environment of a slightly different kind. Again, when material first arrives, it can be gradually acclimatized to its new surroundings by the appropriate regulation of temperature in a certain building.

When the site was first explored, it had three factors of value from the physical and engineering aspects. These were: (1) a constant temperature so low as 47° F. inside the workings, as already mentioned; (2) easy access to electric power; (3) water, sufficient for engine cooling. In view of (1), it was considered that a satisfactory relative humidity in the buildings could be obtained by temperature-control alone, that is, there would be no need for a permanent de-humidifying plant. This relative humidity was provisionally fixed at 55–60 per cent at 62° F. It should be maintained constant to within 3 per cent. This is a narrow tolerance. The point is that once a relative humidity between 55 and 60 per cent—say 58 per cent—has been set up within a building fully occupied with pictures, then it is undesirable that fluctuations should lead to higher values than 61 per cent or lower values than 55 per cent. Owing to the impossibility of forecasting exactly what would happen with such an indefinite 'population' as a combination of panels and canvases, it was agreed to proceed on this basis. To anticipate for the moment: experience of a full year's working has shown that the plant gives, as an example, a relative humidity of 57 per cent at 64° F., with a variation in the former of less than 2 per cent over a period of many months. In general, the temperatures in the various buildings are some 2°–3° F. higher than anticipated, if the correct relative humidity is to be obtained. Of the two factors, relative humidity is decidedly the more important. The reason for this slight temperature excess, and an indication of the methods to be adopted to reduce it, will be considered later. The question of the influence of temperature upon mould growth has also been taken into account.

As already mentioned, each building has its own plant room or rooms containing the necessary fans for air distribution, heating batteries, dampers and automatic controls, the plant varying in output according to the requirements of each building. The essential equipment consists, in each plant, of an electrically driven fan drawing air through a suitable filter, delivering it over a heater battery into a simple plenum in the chambers.

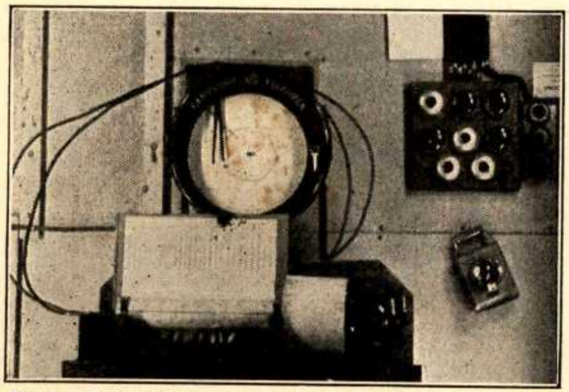

Fig. 5. HYGROMETER, CONSISTING OF DISC-TYPE TEMPERATURE RECORDER AND ASPIRATING SYSTEM.

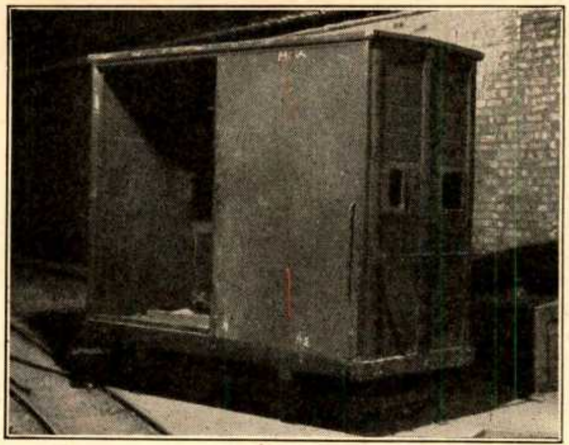

Fig. 6. CLOSED TROLLEY (ONE OF THE FOUR SIDE-DOORS REMOVED) FOR CONVEYANCE OF PICTURES BETWEEN VARIOUS STORAGE BUILDINGS.

Warm air is distributed as evenly as possible through ductwork having low-velocity outlets, and is controlled by louvre and slide-type dampers. Provision is made for partial or total re-circulation of the warmed air, and the proportion of fresh air introduced can be controlled. The unusually stable temperature conditions outside the buildings make thermostatic control as ordinarily understood unnecessary. Overriding high-temperature protection is provided and remote warning of a rise or fall in temperature exceeding 2° F. is given.

The only variable is that of electricity supply voltage at the terminal of a long and heavily loaded rural system, and this is compensated by hand adjustment of the calibrated louvre dampers, and by switching off sections of the heater batteries. This maintains conditions well within the differential limits of commercial thermostats and without the need for heavy voltage control equipment.

Normally, the system works on almost full recirculation of air, with a change of about four per hour. The operating cycle begins at the plant room, where a very small amount of fresh air at 47° F. and 95 per cent relative humidity is 'bled' into the system through intake louvres. The air passes into the filters, mixing with the recirculated air drawn from the chambers. Then it passes through the fan, across the heating battery, through the duct system and is delivered to the rooms through a series of suitably placed orifices. Then the air is drawn back to the plant room through 'recirculation openings' normally kept open. Excess fresh air drawn in at the plant room displaces a part of the stale air through 'evacuation valves' provided for the purpose. When fresh air is being drawn in and filtered there is always a slight outward pressure from the rooms which assists in preventing introduction of any dust from outside.

On occasions, staff is required to work inside the rooms and then the air can be freshened by opening fully the fresh air intake louvres, and closing the 'recirculation louvres'. Air escapes through the evacuation valves. For a given heat input, the temperature then tends to fall, and if the blow through is of long duration, the heat input must be increased.

The advantages of almost complete recirculation are a reduced power consumption for heating, and less heat loss to parts of the workings outside the buildings where the natural ventilation is sluggish.

There has been experience of local temperature rise to 52°–53° F. from 47° F. with decrease in thermodynamic efficiency, and to overcome the consequent rise of relative humidity in the rooms while maintaining temperature, it has been necessary to use calcium chloride as a pre-drying agent for fresh air entering certain plant rooms, and to install powerful fans to draw on the vast volume of air at 47° F. in other parts of the workings. At the worst, in one part, a maximum temperature of 66° F. has been necessary to maintain 58 per cent relative humidity. Energetic measures are being taken to introduce cool air to this locality, and shortly it is expected that it will be reduced to uniformity with the rest of the system.

The flexibility of the whole system is important. Certain valuable material needs individual treatment, and conditions in a building or part of a building can be readily adjusted without any widespread disturbance of conditions.

Throughout, it must be remembered that fungus and moulds constitute a formidable danger to pictures. Research shows that at such a modest figure as 68 per cent relative humidity, especially at temperatures of above 70° F., trouble may occur. Free circulation of air is an effective counter weapon. This is amply provided for in each building. A number of trial canvases and panels have been placed in various parts of the workings—outside the storage chambers—to observe what happens to them in air at around 47° F. and approximately saturated. Moulds were observed well within a month and, in one case, in eighteen days. Constant vigil is kept, not only on the pictures, but also on all incidental woodwork and fabric. Routine inspection is undertaken at short intervals.

The recording instruments in use are simple but essential. In every building there is a hygrometer of the type shown in the illustration. These consist of a standard double-pen disc type mercury-in-steel temperature recorder, adapted to work with an aspirating system composed of a couple of asbestos fibre tubes through which air is drawn by a small fan and motor. In one tube is the wet bulb, and in the other the dry. From the former, a suitable wick dips into a trough of distilled water. (The air-flow is at approximately the same rate as that generated by a psychrometer or whirling hygrometer.) From standard tables, and from the reading of the wet- and dry-bulb temperatures, the relative humidity in the chamber is known at any moment. Calibration with a psychrometer, as a check, is carried out at frequent intervals. These composite hygrometers have been found most satisfactory: a little difficulty was experienced initially in getting the exceptionally large amount of wick to saturate evenly and continuously, but this has been overcome. If the plants are stopped down for a couple of minutes, a decided knick is observed on the charts, thus giving confidence in rapid reaction.

Thermometers are placed at every recirculation louvre throughout the buildings, so that engineering staff can read them from the plant rooms on their patrols. A series of 'standard temperatures' have been worked out empirically, corresponding to the desired conditions within.

Outside the chambers, at various points in the workings, temperatures are recorded daily, to make sure that the ventilation remains satisfactory.

The possibility of electric power breakdowns and failures has been most carefully considered. On this account a 140 h.p. low-speed Diesel-alternator, capable of taking the whole load of motors, fans, heaters, lights and accessories, has been installed. Due to the isolated situation and the severity of local conditions, calls upon the emergency plant are not uncommon. Before the pictures were moved in, a stringent test was made, the generating plant maintaining the whole load continuously for a week. This was thought necessary in view of the reliance placed upon electric power to keep the relative humidity in the buildings from rising (within a matter of a few hours) to dangerous limits. Fortunately, circumstances are such that a more rapid deterioration is not to be expected, but there is not a great deal of margin in this respect. Almost equally important is the need for prompt—almost immediate—restoration of lighting after a breakdown. Experience has shown that it is never more than 2–3 minutes before the stand-by plant is running and normal conditions return. The double calamity of a failure of both electricity supply and stand-by plant at the same time has been envisaged, and super-emergency measures designed to mitigate such a situation so far as possible. There is, of course, staff on duty day and night. As mentioned before, an adequate (but not limitless) supply of water, capable of being treated for use in engine cooling, is at hand.

Indications have already been given of the somewhat heavy engineering works involved in this whole project. To conclude this section, some details may be of interest. Initially, the site (for the purpose in view) was practically without access. A new road, entailing some considerable excavations and embankment, was therefore constructed. Within the workings themselves, enlargement of adits and levels necessitated the blasting and removal of some 3,000 tons of rock (including work now in hand for the improvement of ventilation). In addition, a further 2,000 tons were removed by hand-labour from the floors before it was feasible to begin the erection of the storage buildings. In this enterprise a special appreciation must be made of the work of the local company's manager, under whose direct supervision these operations were all carried out. He discharged this task rapidly, and thanks to his knowledge of the local strata, without accident of any kind.

For the necessary transport of pictures and stores (including engineering equipment), the National Gallery needs about a quarter of a mile of underground narrow-gauge railway. The maximum gradient encountered is 1 in 20 for a few yards. Special rolling stock was built for it by one of the main-line railway companies. An example is shown in the illustrations. These trolleys (propelled by hand) have proved invaluable. In fact, it would have been impossible to have 'moved in' without them. Day in, day out, they are in regular use.

Future Problems

Large-scale research is scarcely practicable in a repository such as has been described, especially as the prime motive is that of conservation of the nation's great collection. Nevertheless, the future is not being left wholly to itself. A sizable body of data relating to temperature, relative humidity, condition and reaction of materials is being assembled, and may well take its place in contributing towards the post-war design of museums and galleries, and to the choice of environment considered best for works of art. It is possible that full air-conditioning of such institutions in large cities and certain other places might be found to be financially desirable, when the sums spent annually in restoration and repair of paintings are critically reviewed. Careful inspection will always be needed, but the experience so far of housing a collection of pictures below ground under controlled conditions, scientifically planned, is decidedly encouraging. It would be a pity if some of this could not be translated into terms appropriate to times of peace. Many great pictures are probably now going through severe hardships and many vicissitudes. Those for which the Trustees of the National Gallery are responsible, however, are at present enjoying a climate of such salubrity that the greatest problem for the future is to foresee how they will react when they leave it.

WILD BIRDS AND HOME-GROWN FOOD IN BRITAIN

By DR. WALTER E. COLLINGE

WRITING in NATURE in July 1918, I stated: "It behoves us to awaken and to take heed where we stand, or for some years to come our land will groan with the cry of desolation, due to our apathy and the ignorance and neglect of the ways and habits of our insectivorous birds, and the wanton destruction of what has ever been Nature's means of adjusting the complications of animal life, which man in his ignorance is seeking to pervert". In the quarter of a century which has since passed, the nation has lost millions of pounds worth of home-grown food.

For very many years past, I have given warning of the vital importance of framing a sound and logical policy relating to the protection and destruction of wild birds. To a very large extent this warning has fallen on deaf ears. Little or nothing has been done, the *laisser-faire* policy has been pursued, and at the present moment it looks as if Nemesis were about to overtake us. No useful purpose would be served by re-opening here the whole question. It is a difficult one, touching various interests and prejudices; but we must no longer shut our eyes to the various extremely dangerous suggestions that are being so widely circulated, and, I fear, in some cases being put into practice.

At the moment, the whole of Great Britain is deeply concerned in the production of the maximum amount of home-grown food and in being able to harvest it. In so far as it lies in the range of human endeavour, there must be no mistakes made that will lessen the harvest of 1943. We now know that big, clean crops of all kinds can be raised and harvested, provided they are kept free from pests and disease. Such pests as wireworms, leather-jackets and other soil-inhabiting insect larvæ exact an enormous toll on root and cereal crops. In a like manner, the larvæ of various moths and flies, and also aphids, take their toll of the fruit and other crops. The soil may be treated with various chemicals and the fruit trees sprayed, but both are only partial remedies and both processes are expensive and demand man-power.

Two primary facts stand out, namely: (1) Wherever the insectivorous birds of a district or districts are destroyed, either purposely or through climatic or other causes, there is an accompanying insect oscillation which is not reduced until the balance of bird life is restored. (2) In the case of certain insects the numbers of which remain relatively constant, the controlling influence is largely, if not entirely, due to the uniformity of the bird life from year to year.

Nearly sixty years ago, John Curtis told us that if the depredations of injurious insects could be brought under control "the benefit would exceed everything of which at present we have any conception". The amount of insect food that insectivorous birds will eat is very large. I have given the following as an illustration and in an endeavour to bring the fact home to the public. Assuming that there are 32,000,000 acres of land under cultivation in Great Britain and that we have a pair of birds to every four acres, these 16,000,000 would consume annually 135,411,328,000 insects, and these would be destroyed just at the season of the greatest agricultural activity and would be accomplished without any outlay of men or money. Yet it now seems that ill-informed people are advocating the destruction of rooks, gulls, blackbirds, thrushes and other insect-eating birds.

Very briefly, let us examine the facts concerning the few species of useful birds mentioned above.

Rook. During the past fifty years, this species has received more attention as regards its food habits than any other British species, and the general consensus of opinion is that this bird is economically of the very greatest value. The nature of its food has been shown to consist of large quantities of injurious insects and their larvæ, some of which are most difficult to destroy and which annually exact a huge toll on the produce of the land.

Sea-gulls. No more short-sighted policy than that of the destruction of sea-gulls has ever been promulgated, and if carried out will have results of a most devastating nature. We have at last given up the foolish idea that sea-birds generally feed only on fishes and therefore are impoverishing the supply. Nay, we have still further advanced, for we now realize that, so far as sea-gulls are concerned, the percentage of fish eaten is comparatively small, very small in some cases, and much of it is obtained from the garbage of the shore.

The black-headed gull—the bird that follows the plough—for the greater part of the year feeds upon injurious insects. The total percentage (stomach contents) for the year is 24·70, whereas the fish content is 3·73 per cent. The highest fish content for any month in the year was in November, with 12·85 per cent, whereas the percentage of injurious insects during April to October was 33·01, with the following figures respectively 32·96; 28·0; 37·30; 31·38; 38·83; 26·62; and 26·0.

"Of 664 specimens examined only 143 contained fish remains and 267 contained no marine organisms whatever."[1] For the common gull the figures were, injurious insects 14·66 per cent, fishes 5·16 per cent, and for the herring gull 9·52 per cent and 17·55 per cent respectively.

Blackbird. In 1924, I pointed out[2] that we had too large a resident population of blackbirds. From numerous observations made by myself and many correspondents, there was no doubt that the population seriously decreased during the winters of 1938–39 and 1939–40 (December to March) and investigations made during 1938 and 1939, when compared with similar ones made in 1933–34[3], showed that there was an increase in the percentage of injurious insects eaten from 22·0 to 30·5 per cent, and a slight increase in the percentage of slugs and snails. There was a striking decrease in the percentage of cultivated fruits and fruit pulp, which dropped from 25·5 per cent to 15·2 per cent. Complaints respecting this bird have been very few during the past few years.

Thrushes. The missel-thrush and the song-thrush are the only ones that concern us. Of the total food consumed in a year by the former, 30·5 per cent consists of injurious insects and 16·5 per cent of cultivated fruits. The figures for the song-thrush are 32·0 per cent and 15·0 per cent respectively.

Tits. Who it was who first accused the tits of being injurious I do not know, but I fully agree with Yarrell that "none can be more mistaken than these men". The great tit consumes 66·5 per cent of injurious insects per year and 3·6 per cent of fruit, while the blue tit takes 78·0 per cent of injurious insects and 6·0 per cent of fruit.

The above figures need no comment; their significance is patent to every thinking man and woman.

There are certainly a few injurious birds, chief among which are the starling, the house-sparrow and the wood-pigeon. Repressive measures for dealing with these are long overdue.

In 1921 I summed up my investigation[4] on the starling by stating that, failing some action as there outlined, "the agriculturist and fruit-grower will be left faced with a growing enemy which is devastating their crops and inimical to their interests, and the country with a portentous factor which is adding to the scarcity of home-grown food. In short, the starling has become a plague in the land and a source of great national loss". Observations made during the past eleven years fully bear out this statement.

It has been estimated that the house-sparrow occasions a monetary loss of £50,000,000 a year. Whether this amount is correct or not is of little matter. What we do know is that they consume a large amount of home-grown food, and if they were reduced to half of their present number, it follows that half of the huge total would be saved.

Before it is too late, it is necessary that the beneficial species I have mentioned above should be scheduled and the destruction of them or their eggs be prohibited. I feel certain if this were done now, even if only as a temporary measure, it would demonstrate once and for all what a powerful factor they are in ensuring prosperous agriculture.

Writing some little time ago I stated[5], "The 'man in the street' and others in high places may not have realized this, but nevertheless it is true, and unless we do realise the facts and take action our agriculture, forestry and all kindred arts are doomed. These are strong words, but only uttered after a life-time's acquaintance with the subject. . . . The Government and the whole of agricultural Great Britain are evading a great and vital problem of paramount importance to the nation and charged with its future existence."

Long ago the prophet Joel wrote, "Tell ye your children of it, and let your children tell their children. . . . That which the palmerworm hath left hath the locust eaten; and that which the locust hath left hath the cankerworm eaten; and that which the cankerworm hath left hath the caterpillar eaten. . . . The field is wasted, the land mourneth; for the corn is wasted. Be ashamed, O ye husbandmen, howl O ye vine-dressers for the wheat and for the barley; for the harvest of the field is perished."

Let us hope that we shall not have to give voice to similar words at the end of 1943.

THE ACADEMY OF SCIENCES OF THE U.S.S.R.

PROGRAMME FOR 1943

By ALEXANDER BAIKOV

Vice-President of the Academy

MORE than in any previous year, the plan of work for 1943 of the Academy of Sciences of the U.S.S.R. is designed to aid the Russian armed forces and war industries in securing a victorious termination of the War. Our main work will be directly concerned with improving armaments and therefore cannot be divulged; but it may safely be said that, if in the past year Soviet physicists, chemists and engineers did much to improve and increase the supply of materials, instruments and tools for war industries, in the New Year they will do considerably more.

Although the scientific effort of the country is almost entirely devoted to war needs, this does not mean that pure scientific research has been suspended. Russian mathematicians and physicists, for example, are continuing their investigations into the theory of numbers, the dynamics of the atmosphere, etc. However, the main effort this year will be focused on mobilizing the material resources of the country and increasing the supply of raw material for war industries. This work is under the direction of the Commission for the Mobilization of the Resources of the Urals, west Siberia and Kazakhstan, under the chairmanship of Vladimir Komarov (of the Academy), the Commission for Mobilization of the Resources of the Middle Volga and Kama Regions, and similar commissions which will make an all-round study of the problems involved. The plan of work of the Academy's geological and geographical department is devoted to exploration and study of new natural resources which may contribute to the country's defensive might, chiefly to the discovery of new deposits of manganese needed for manufacturing various alloys, aluminium, nickel, wolfram and other ores, as well as non-metallic minerals such as fireproof materials, for which there are now great industrial demands. Much work is also planned in locating new oil deposits and increasing the recovery in functioning oilfields. Great hopes are placed in the Volga-Bashkir expedition. Oil will also be searched for in the Permian Kama coal deposits of the Tatar Republic. As before, considerable attention will be paid to the secondary recovery of oil. Adequate coal supply is just now decisive for industry in the U.S.S.R., and Soviet men of science will make every effort to discover new deposits and help to increase the output from those already being exploited. The production of motor fuel from coal and shale of the Urals, Karaganda and the Far East occupies an important place in the plan of work.

Among eminent Soviet men of science who are engaged on the problem of mobilizing the country's natural resources, under the direction of Vladimir Komarov, president of the Academy of Sciences, are Alexander Fersman, Vladimir Obruchev, Alexander Skochinsky, Pavel Stepanov, Lev Shevyakov and Alexander Zavaritsky.

No less important a place in the Academy's plan is held by the problem of increasing the yield of cereal and industrial crops, such as rubber-bearing plants, cotton, sugarbeet, and potato; and also the manufacture of artificial fertilizers. The working out of new industrial processes and the intensification of existing processes constitute the central item in the plans of the Department of Technological Sciences of the Academy. Considerable attention will be devoted to the development of the power resources of the eastern regions of the country so as to ensure an adequate supply to the new industrial areas. Efforts will be made to improve industrial gas generating stations, and also to put the gasification of new forms of fuel on an industrial footing, utilizing sources available in various localities and thus obviating the necessity for long hauls of fuel. This will involve working out the principles of design of highly efficient gas-generating installations. The Department will also deal with problems connected with the economic restoration of the liberated regions.

In chemistry, work will be concentrated this year on industrial utilization of raw materials in the eastern regions, and the manufacture of synthetic rubber, plastics, pharmaceutical preparations, etc. The Institute of Chemical Physics will continue the study of the theory of combustion, which is of cardinal importance in the design of prime movers. Alexander Porai-Koshitz will direct researches into the utilization of the chemical products of coke in industrial plants of the eastern regions. Peter Kapitza will continue his work on the design of a powerful machine for making liquid oxygen.

The work of biologists will include investigations on the healing of wounds, and also on the prevention of infectious diseases. It is proposed to treat shock and tetanus on a wide scale by the method of Lina Stern, of the Academy of Sciences, which involves influencing nerve centres by spinal injections. Efforts will be made to discover more effective blood-clotting substances, stimulants, pain-relieving and fatigue-relieving substances.

Historians will engage on a number of interesting investigations, including the history of various nations—the Slavonic history of wars and international relations, the history of the second World War, the history of Russian culture and a chronicle of the present Soviet-German War will occupy chief place. The Department of Languages and Literature is compiling a work on language changes during the present War, a dictionary of modern Russian edited by Sergei Obnorsky, and a study of the mutual influence of Russian and English literature in the nineteenth and twentieth centuries.

The programme of work I have outlined was endorsed by the council of the Academy of Sciences at a meeting held in Moscow under the chairmanship of the president, Vladimir Komarov.

OBITUARIES

Prof. Arthur Willey, F.R.S.

Dr. Arthur Willey, emeritus professor of zoology in McGill University, Montreal, died on December 26. He was the son of the Rev. William Willey, a leading minister of the west of England. After education at Kingswood School, Bath, he proceeded to University College, London, where in his second year he worked in Lankester's research laboratory. After taking his degree he was sent to the Stazione Zoologica, Naples, where he did research on Tunicates and Amphioxus, afterwards returning to the College as fellow.

Amphioxus was reinvestigated by Willey from every aspect, as it was a key animal in the controversies on the ancestry of vertebrates. In opposition to Cuvier's four types of structure, Saint-Hilaire sought a unity of plan homologizing insects and vertebrates, Leydig especially comparing their brains. Kowalevsky followed in 1866 with researches on Amphioxus, but in 1875 Semper and Dohrn independently maintained an annelid ancestry for vertebrates. In the early nineties most schools of zoology seriously discussed all these views, but in 1894 Willey's book, "Amphioxus and the Ancestry of the Vertebrates", caused almost a revolution. He had tried his matter out in a course of lectures at University College, when he had insisted on his practical work including every stage in the development and structure of Amphioxus in comparison with Ammocœtes.

At this time the leading zoologists of Great Britain became excited about the Pearly Nautilus. This "pre-tertiary creation" had been re-examined by Graham Kerr, following on work by Ihering and Ray Lankester, and a knowledge of its embryology was desired. To this end the managers of the Cambridge Balfour Fund elected Willey their student and continued him for five years. Nautilus had first been described by the great Dutch naturalist Rumphius, together with many Malayan 'plant animals'. Owen was excited by the anatomy of a later specimen, but Cuvier did not live to see it in the flesh. Its shell had been known from the time of Aristotle, but it was always compared with that of the argonaut, which floats on the sea-surface in connexion with the development of its eggs. It was supposed to be related to Spirula, the soft parts of which were equally scarce, although its shell is common on tropical beaches. This form, however, has a floating life with a shell that has been reduced to a minimal weight and size and has become almost internal, whereas Nautilus is a ground feeder in comparatively deep water with an immense shell, the animal being in a terminal chamber out of which its crawling and feeding tentacles protrude; its flattened shell is held upright on the ground. Specimens which had floated to the surface, on which the early anatomy had been studied, were mostly moribund. Willey trapped specimens in relatively deep water; the bait was mashed-up crayfish wrapped in coconut fibre so as to be invisible to the animal, which proved to be attracted by smell, its pinhole eye not being the efficient eye of most cuttle fish. The necessary breeding for the embryology did not succeed with the means at Willey's disposal, but the anatomical account published in the "Zoological Results" of his expedition is classical.

The scene of Willey's first labours was in Blanche Bay, New Britain, now known as Rabaul. It is a circular rocky bay open to the east; a camp was pitched on an island erupted in 1878. The floor at 50 fm. and deeper was ridged by lava lines with deep chasms between, the feeding ground of Nautilus. A coconut plantation covered the low ground and was an oasis of civilization due to Parkinson, almost a 'king'. The island had been partially subdued by that warlike missionary, George Brown, but conditions were primitive in the extreme, the natives still in the stone age, and Willey was in constant danger, but at all times quite imperturbable. Here in the primitive native canoes with a 'boy' or two, he went out day by day, laying his baskets, hand trawling and sweeping his surface nets, returning to an open shelter and cooking his taro, breadfruit or yam with an occasional fish, a tunicate flavour often added from his experimental colonies. New Guinea, to which he went next, was even worse, the natives being flesh rather than fish eaters. It was alleviated by the purchase of a small sailing cutter. The D'Entrecasteau and Conflict Groups were visited and Willey was anchored off Buna for some time.

When sailing, one of the boys jumped overboard to secure a floating cuttle bone and off this, when placed in a pan of water, were secured quite a number of organisms, including some which could both crawl and swim. These proved to be Ctenoplana, a single specimen of which had been described in 1886. As it crawls it is a flatworm, and as it swims a ctenophore, transparent and provided with swimming plates. This important intermediate form, later worked out in Haswell's laboratory at Sydney, made up for many disappointments. There was also a lancelet, Asymmetron, previously caught only in the Bahamas but now known to be cosmopolitan.

New Guinea proving unsuitable for Nautilus, a move was made via New Caledonia to the Loyalty Islands in the New Hebrides, even then governed by a condominium between France and England. Off Noumea, an enteropneust, Ptycodera, was found; this with later specimens was the subject of a long memoir, a comparison with West Indian forms and Amphioxus. A settlement was finally made at Sandal Bay, Lifu, and here for eight months Willey tried to make his Nautilus breed, but its heavily yoked eggs were always infertile. The island population (7,000) were enjoying the everlasting Catholic v. Protestant fights, and so far as the French authorities were concerned there was, as usual, little generosity. Land as well as marine animals were collected and on these more than thirty memoirs were published in the "Zoological Results". Willey's special contribution among these was on a primitive beast from Rabaul, *Peripatus novæ-britanniæ*; this gave him great pleasure as he had an unbounded admiration for F. M. Balfour, whose classical memoir on *Peripatus capensis* he greatly admired. A further visit to New Britain terminated two years of field research.

On his return, Willey became lecturer in biology at Guy's Hospital, London, and he was shortly after elected to the Royal Society. He did not like this soul-killing job, and social conditions in England were to him unpleasant, while the climate was anathema. He was hence glad to go to Colombo as director of its Museum, a post he held from 1902 until 1910. Here in Ceylon he found a fauna little known except for Kelaart's Prodromus, 1892. He supposed he would find many animals peculiar to the island and a fauna comparable to the flora as described by Tennant and Trimen. He set out to examine the mammals but found no important forms not already known from southern India. The phenomena of endemicity were best represented in the reptiles, now being monographed by Deraniyagala. The fauna is analogous with those of Great Britain and Tasmania in relation to their neighbouring continents, but there proved to be relationship to the East Indies. Educational requirements were the subject of several reports, as also the sea and freshwater fisheries and various molluscs. The Museum began to take a scientific shape, no longer merely a collection of curiosities. It was an uphill job at first, the attitude of the ruling authorities being deplorable, while collectors seldom appreciated the necessity of accurate data. The *Spolia Zeylanica* was founded as a quarterly journal, since when zoology in Ceylon has never looked back. Willey's own researches wandered into the marine worms connected with the pearl banks. As an amusement he was collecting data for a book, "Convergence in Evolution", which at the time created great interest among students, stimulating the closer study of the living forms.

In 1911 Willey commenced his courses at the McGill University, where he remained for the rest of his life. From here he always wrote happily of his teaching and life in the University—and as an adopted son of Canada. He had a research interest which wandered into every side of animal life, plankton, placentation in the beaver, Branchioderma and Branchiotrema, general marine conditions, Arctic Copepoda and even a research on "Reductions and Reversions in the Wing Venation of the Stoneflies". He was called upon to advise on many economic sides, and Macallum paid high tribute to the value of his opinion. The University Club especially interested him, and with age he became less sensitive and retiring, while preserving a pleasant liveliness in disposition. He acquired a solid popularity, for he was always dependable. J. S. GARDINER.

Prof. F. M. Cornford, F.B.A.

PROF. F. M. CORNFORD, who died at Cambridge on January 2, at the age of sixty-eight, was the first occupant of the chair of ancient philosophy established there in 1931. He became a fellow of Trinity in 1899, and was a lecturer in classics until his election to a readership in 1927.

His published work was abundant and falls naturally into two periods, divided by the War of 1914–18 during which he served in the Ministry of Munitions. The earlier period is especially marked by an interest in the origins of Greek philosophy, and in the religious conceptions from which it developed. Thus the leading principle in "From Religion to Philosophy" (1912) is a distinction between the 'mystical' school, represented by Heraclitus, Pythagoras, Empedocles and Plato, a school which seeks primarily to preserve what the religious consciousness values, and a scientific school, including Anaxagoras, the Atomists and others, which tends to discard religion for rationalism. In "The Origin of Attic Comedy" (1914) he sought to explain the structure of the extant plays by examining the ritual forms which lie behind them; here he was influenced by the work of Jane Harrison and Frazer. An earlier work, "Thucydides Mythistoricus" (1907), was a daring re-interpretation of the historian's mental background and of the religious framework which governed the selection and presentation of his material.

It is no disparagement of these earlier and more speculative works to say that Cornford's most permanent achievement is to be found in the post-war books, "Plato's Theory of Knowledge", "Plato's Cosmology" and "Plato and Parmenides", in which he translated and interpreted four important Platonic dialogues. Departing from the ordinary form of commentary, he skilfully interwove translation with running comment in such a way as to produce books which can be read as continuous wholes. To readers with scientific interests the edition of the "Timæus" called "Plato's Cosmology" will probably appeal most strongly: it reveals perhaps most fully its author's many-sided knowledge and power of argument; few classical scholars could have dealt so successfully with the problems of astronomy and physics, physiology and medical theory which the "Timæus" presents.

Jointly with P. H. Wicksteed he translated Aristotle's "Physics" in the Loeb series, and the notes and summaries marked by his initial show how competent he was to interpret Aristotle's discussion of such fundamental concepts of science as time, space, movement and infinity. About a year ago his last book appeared, a translation of the "Republic", of which it can only be said here that it is more than a translation, and makes an excellent introduction to Plato for the 'unprofessional' reader.

Much important work of Cornford's is contained in periodicals, especially in the *Classical Quarterly*: it includes an examination of the Pythagorean number-doctrine, a paper on "Innumerable Worlds", and a new interpretation of Anaxagoras's theory of matter. Finally, his chapters on philosophy down to Aristotle in the "Cambridge Ancient History" can be warmly recommended to anyone wishing to make a first acquaintance with ancient thought.

R. HACKFORTH.

Sir Henry Maybury, G.B.E., K.C.M.G., C.B.

SIR HENRY MAYBURY, who died on January 7 at the age of seventy-eight, was a wholesome-looking, thick-set man with a capable headpiece, a general friendly attitude towards his fellows and a tendency to come to decisions to which he adhered with what admirers called his determination and critics his obstinacy. His first fame came when he was surveyor to the County of Kent (1903). That was about the time when a friend and I were organizing the Gordon Bennet motor race in Ireland. Its description by a jarvey illustrates the position: "Those parts of Oireland that's not consailed wid dust is covered wid people".

In circumstances like these, Maybury made his successful efforts in Kent to abate the intolerable dust which cursed the early days of the motor era. He courageously used tar-bound instead of water-bound macadam, and soon found he had achieved the great advance of making roads waterproof. He pushed forward with it with insistence, was hailed as a saviour by the owners of riparian property, and made Kent roads a model for the rest of the country.

Somewhere on Salisbury Plain a number of consecutive lengths of road all bearing the same traffic (that is, with no side junctions) and suitable for considerable speeds were prepared, each according to a different formula. The run being substantially free from bends and the surface level, it called for no stops, starts, accelerations, swerves or brakings. As these are the chief causes of road wear, no perceptible deterioration or wear by vehicles revealed itself. What did transpire was that the waterproofing with tar, bitumen or the like minimized what is a substantial source of road costs, even in unused roads, namely, land creepage, vegetation, weeds and, above all, deterioration by sun, rain and frost. The waterproofing would pay for itself in upkeep economy. Before long, water-bound macadam, gravel, and slippery roads made with chalky marl began to disappear.

Maybury was no researcher. His training as a railway engineer inclined him rather to the *ad hoc* experiment. Besides, the Harmondsworth Research Station for road materials to which so much of recent progress must be referred was not then in its stride. As chief engineer to the Road Board (1913) and later as chairman of the London and Home Counties Traffic Advisory Committee (from 1924) he accumulated much traffic experience. There came before him the noteworthy reports of the Metropolitan Police between 1920–27. They revealed year after year for seven years that high vehicle speeds occupied a far smaller place in the records of fatal accidents in town than did low speeds. Speeds not exceeding walking pace (less than 5 m.p.h.) were concerned in six times more deaths than were all speeds above 20 m.p.h. Moreover, a predominant majority (80 per cent) of fatal accidents occurred when the previous speed of the vehicles involved had been less than 15 m.p.h. On this Sir Henry Maybury's ripe experience led to the notable phrase often quoted from Report No. 61434–12: "A careful examination of these reports clearly indicates that there is an intimate connexion between the number of street accidents and traffic congestion". That was a new idea.

The moral is clear. Unfortunately for safe traffic flow afoot or awheel in Greater London, Sir Henry resigned in 1933, and now many of us sincerely deplore the final loss of his clear-sighted "obstinacy".

MERVYN O'GORMAN.

Prof. F. J. Allen

DR. FRANK JAMES ALLEN died on December 28 at Letchworth; he was born in Somerset in 1854. He went to Cambridge to study medicine and came under the influence of Michael Foster, and was one of the many physiologists who was inspired by that great teacher. He was awarded first-class honours in the Natural Sciences Tripos in 1878. He went to St. George's Hospital, London, where he studied clinical medicine, and later became an assistant medical registrar at that Hospital.

Sometime after qualifying in medicine, Allen returned to Cambridge as assistant demonstrator in physiology under Foster. He was elected a member of the Physiological Society in 1888, and later became a member of the Committee of that Society. He was appointed professor of physiology at Mason College, Birmingham, in 1888, and played a part in the negotiations which led to the formation of the University of Birmingham. He resigned his professorship in 1898 to enter general practice.

While in Birmingham, Prof. Allen gallantly captured a dog suffering from rabies and in doing so he was bitten by the animal. He went to the Pasteur Institute in Paris for treatment, and described his experiences as a patient at the Institute in the *Birmingham Medical Review* of 1898. The success of the treatment he received at the Institute is evident by the fact that he lived for a further forty-five years.

In his younger days, Allen made several contributions to physiological knowledge, and later devoted his spare time to a study of ecclesiastical architecture, publishing a book, "Great Church Towers of England", in 1932.

Allen was a widely read and cultured man, very modest and unaffected, and though many of his generation have passed away he is remembered by those who knew him with great affection.

H. P. GILDING.

WE regret to announce the following deaths:

Prof. A. K. Cajander, formerly professor of forestry in the University of Helsinki and director-general of the State Board of Forestry in Finland, who was Prime Minister of Finland during 1922–24 and 1938–39 and Minister of Defence during 1928–29, on January 21, aged sixty-three.

Capt. B. S. Cohen, formerly director of the Post Office Research Station at Dollis Hill, London, aged sixty-nine.

Prof. Edmund S. Conklin, formerly head of the Department of Psychology, University of Indiana, on October 6, aged fifty-eight.

Mr. A. H. Cornish-Bowden, for many years surveyor-general to the Government of the Union of South Africa, on December 5, aged seventy-one.

Prof. J. F. Craig, professor of veterinary pathology in the University of Liverpool.

Dr. Cyril Crossland, the first director of the Marine Biological Station at Ghardaqa, Gulf of Suez, on January 7, aged sixty-four.

Lord Hirst, honorary member of the Institution of Electrical Engineers, chairman of the General Electric Company, on January 23, aged seventy-nine.

Dr. A. L. Lowell, emeritus president of Harvard University, where his tenure of office, 1909–33, covered a critical period in university affairs, on January 6, aged eighty-six.

Dr. Alexander Russell, F.R.S., formerly principal of Faraday House, London, on January 14, aged eighty-one.

Prof. J. Strohl, professor of zoology and comparative anatomy in the University of Zurich.

NEWS and VIEWS

Science in the Service of Art

SIR KENNETH CLARK, director of the National Gallery, has sent the following notes referring to the article on "The National Gallery in War-time" by Mr. F. Ian G. Rawlins which appears on p. 123 of this issue. Mr. Rawlins has been scientific advisor to the National Gallery since 1934. To him the Gallery owes its admirable laboratory with X-ray, infra-red and ultra-violet ray apparatus, and equipment for microscope, tintometer and spectroscope work; and when the War began he was conducting important researches into the structure of pigments and the physical condition of old paintings. A few of his experiments in radiology are contained in the publication "From the National Gallery Laboratory", which was reviewed in NATURE of February 8, 1941, p. 165. In the years before the War, he was also closely concerned with the methods by which the pictures might be safely evacuated, and when finally it became desirable to place the whole collection in entirely bomb-proof subterranean vaults, he was responsible both for the discovery of a suitable site and for planning the equipment described in the accompanying article.

In the construction of the shelters and installation of plant, Mr. Rawlins worked in collaboration with the Ministry of Works engineers, and thanks to his foresight and attention to detail all the difficulties of this ambitious undertaking have been completely overcome. From the point of view of physical conditions, there is no doubt that the National Gallery pictures are better off than they have ever been or will be in the future. Mr. Rawlins's work did not cease when all the plant was installed and in working order. Constant vigilance is necessary to keep the perfect balance of temperature and humidity. In this work Mr. Rawlins has been ably assisted by Mr. Martin Davies, the member of the Gallery staff in charge of the depot, who has brought efficiency and unsparing devotion to the task of conserving the nation's pictures.

Polish Homage to Newton

THE Association of Polish Technicians in Great Britain held a special tercentenary celebration of Isaac Newton, under the chairmanship of Prof. Max Born, in the Mathematical Institute of the University of Edinburgh, on January 17. Addresses were delivered by Prof. E. T. Whittaker and Dr. S. Neumark, formerly *dozent* in aeronautics in the University of Warsaw, and now a flight lieutenant in the Polish Air Force. He was introduced by Major Chodacki, formerly High Commissioner for Danzig. Prof. Whittaker remarked that as the celebration had occurred in 1943, it had fallen in the same year as the quadricentenary of the death of Copernicus. Dr. Neumark, in his lecture in Polish, demonstrated Newton's decisive contribution in the development of natural science by means of a chronological diagram. This represented Newton as the central figure receiving the inheritance of the previous preparatory period, and extending his creative influence all over the world and over numerous fundamental branches of science. Newton's principal discoveries in the fields of mathematics, mechanics, astronomy, optics, aerodynamics, theory of heat and general foundations of natural science were described and illustrated by simple mnemonic diagrams. A rough classification of the whole of Newton's work showed that he made the incredible number of thirty discoveries of the first importance, each of which would have sufficed to confer permanent glory upon the discoverer. Newton's direct practical contributions to industry and to the progress of Britain were illustrated by his work at the Royal Mint, his remarkable steps towards developing mass production and his influence as president of the Royal Society. Dr. Neumark ended his lecture with a brief discussion of the unique problem which Newton's scientific personality offers to students of human creative power and genius. The linking of the centenaries of Newton and Copernicus is a happy prospective for the future relations between science in Britain and Poland.

Engineer or Physicist ?

ALTHOUGH the importance of physics in industry is now almost universally recognized, and the fairly obvious deduction that the application of physics to industry calls for the presence of physicists in the industrial team is beginning to be appreciated, the exact function of the physicist in the team is by no means generally agreed. There are still employers who are under the impression that every physicist is a potential Newton or Rutherford, and others who regard him as a sort of super-engineer, capable of providing an immediate remedy for all the day-to-day difficulties which crop up in the factory. Both classes are likely to suffer severe disappointment. It would, of course, be admirable if every engineer could be his own physicist, or every physicist a master of engineering. Unfortunately, both fields of knowledge are now so vast that this is no longer possible. Progress in industry demands the services of both engineer and physicist, and close and cordial co-operation between them. Cordiality is most likely to be maintained if each has his recognized sphere, and sticks to it.

The matter has recently been discussed by Dr. Percy Dunsheath in an article in *Engineering* (Dec. 11, p. 474). Dr. Dunsheath, who has, as one might say, a foot in both camps, is very well qualified for making a functional analysis of the situation, and his article will repay close study by all responsible for the direction of industry. The article is too long, and too closely knit, for abstraction. Dr. Dunsheath's conclusion is that the physicist's principal function in industry is to provide a liaison between the "continuous spate of new knowledge of the physical universe" and the factory, and so "translating it for early application". "The engineers," he concludes, "must all be physicists up to a point, but the physicist, so long as he carries physics to the utmost boundary of existing knowledge, need not be an engineer. . . . By fundamental research to collect and establish physical laws and the application of this systematized knowledge, the physicist can do much to refine industrial science which ultimately must be the practical work of the engineer."

The 'New Deal' as a Social Philosophy

AN exceptionally interesting interpretation of the origin and nature of the programme known as the New Deal in the United States is contributed by Prof. D. Mitrany to *Agenda* of October 1942. Prof. Mitrany insists that the whole philosophy and policy of the New Deal derives from the fact that the era of the physical frontier has closed and that the United States stands at the threshold of the social frontier. The New Deal is not a programme or an ideology conceived and propagated as a theory before it could be practised. It was set in motion by social necessity ; and a pragmatic attitude, a readiness to experiment, is characteristic of it as a whole, but was more marked during its first stage. The fact that the New Deal is a policy rather than a theory, and an improvised policy, makes it difficult to distil out of its action the social philosophy which inspires it. America's present social forces and trends have developed with the New Deal, and the crystallization of the new outlook has largely been stimulated by realization that the means for a full life were there, but that the old system had failed to make them available.

The measures of the New Deal fall in three broad but well-defined groups : in their effect on the mass of the people ; in their effect on the use of the nation's material resources ; and lastly, in their effect on government. For the mass of the people the New Deal has set out to provide security first, including protection against arbitrariness of economic wealth and power and gradual and continuous improvement afterwards. The activity of the New Deal for the salvage of the nation's material heritage makes an impressive programme, of which the Tennessee Valley Authority provides the outstanding example, as it does also of the changes which the New Deal is bringing about in the government of the United States. In establishing public control of the public use of those resources, the New Deal has broken sharply away from the old system, and the history of the Tennessee Valley Authority provides an illuminating epitome of the passage of public attitude from the 'old deal' to the New Deal and of the struggles that mark its progress. A great constitutional transformation has occurred without any formal changes in the constitution. The New Deal may be said to have brought about three essential changes in American outlook and policy : solicitude for the 'forgotten man' ; solicitude for the country's natural resources and technical equipment ; and a centralized public action for these two social purposes. The United States are passing from a social ideal of individual effort for individual reward to an ideal of mutual effort for common advancement, and Prof. Mitrany points out that the change involves a new outlook, a new method and a new purpose. The New Deal is still in its formative stage, but it is in essence a philosophy of social action. If its ends cannot be reached through international action, it may be thrown back during its next phase, as it was during the first phase, upon action of a national and socialistic kind.

Problems of Communal Feeding

MR. F. LE GROS CLARK has issued a broadsheet on "Soviet Forms in Communal Feeding". Coming as it does at a time when we are witnessing a rapid development of communal feeding in Great Britain, it is of very great interest and importance. Catering for people in large groups is not only economical in food, fuel and man-power, but also provides a good opportunity of improving the nutritional status of those fed. It is obvious from this study that the Soviet peoples are fully alive to both these aspects, and it is interesting to find that they came up against just those difficulties which are being encountered now in Great Britain. Needless to say, they dealt with them in their usual thorough manner. Our own tribulations might have been less had we taken advantage of their experiences. Thus, while we search for some means of preserving the palatability and the ascorbic acid content of meals cooked in kitchen depots and distributed in insulated containers, we read here that : "In 1931 the decision was taken to abandon completely the method of conveying cooked food in insulated containers and to utilise the depots almost entirely for the output of uncooked but partly prepared food of all kinds". In the same year, the wages of the kitchen staff were brought into line with those in other branches of industry. Mr. Bevin is struggling with this point now. Details are given of development, control, training of personnel, official standards to be achieved, 'special diets' sections, school canteens, rural canteens, etc. A study of them is heartily recommended.

Sylvicultural Research in Bengal

MOST of the provinces in India draw up a quinquennial programme of sylvicultural research work and prepare an annual report on the work undertaken in accordance with the programme. For this purpose a sylvicultural research officer is selected from the ranks of the Forest Department. The annual report on sylvicultural research in the Presidency of Bengal for 1940–41 (Government Press, Darjeeling, 1941) is by Mr. D. A. G. Davidson. In connexion with research in such an important branch of his work as sylviculture, which is its foundation, it appears that at a Divisional Forest Officers' Conference held in Darjeeling in 1940 a resolution was passed which reads, "the practice of allowing divisional officers to undertake research independently of the Sylvicultural Branch should be discontinued and no funds should be provided in future for divisional experiments". It is difficult to understand the meaning of, and the purpose underlying, this attempt at granting a monopoly to a research branch. In forestry, the opportunities for observation by the divisional officer, that is, the man who spends much of his time out in the forests in a definite locality which he can thus get to know with some intimacy—and in India this means large areas—are exceptionally advantageous. The officer may be every bit as observant as the research officer and has better, because more numerous, opportunities for carrying out a piece of research work up to a certain point.

The attempt to introduce exotic, faster-growing species in connexion with forestry has become a common habit in many parts of the world. Experiments in this connexion were commenced at Darjeeling and neighbourhood seventy and more years ago. The research officer is still engaged on these experiments. Attempts have also been made to induce seed production by ringing the trees, after the method practised for fruit trees. But most of the trees ringed in Bengal died. In experimental plots in the Chittagong Hill tracts, although the second story species, *Dichopsis polyantha*, *Artocarpus chaplasha* and other evergreen species regenerated profusely, the regeneration of the top species, Garjan (Dipterocarpus), has proved unsuccessful. It may be suggested that the Garjan might be added to the mixture by planting it in lines at 30–40 ft. apart and at such distance in the lines as may be decided, and that big plants should be used. This method has been found successful under somewhat similar conditions in West Africa.

Floatless Pump Control System

LONDEX, LTD., 207 Anerley Road, London, S.E.20, have introduced a patented system ("Lectralevel") of floatless liquid level control, designed for automatically pumping out, filling or maintaining the liquid level in a container and employing a single mercury switch for controlling the pump motor starter. The pump suction pipe may be earthed and used as one side of the control circuit, the pressure of which (25 v.) is derived from a small double-wound transformer supplied from the power or lighting mains. The control circuit is completed through the liquid to be pumped, and only light insulation is required for the electrodes, which may be of ordinary galvanized wrought iron tubing. A shorter electrode terminating at the highest level of the liquid is connected direct to the relay, and when the level rises to this electrode the relay is energized and the pump motor started. A longer electrode is immersed in the liquid to the lowest required level and is connected to the relay by the same lead through a resistance of a few ohms, its function being to pass sufficient current through the relay to hold the latter closed after the level has fallen below the short electrode. When the liquid level falls beyond the longer (lower) electrode, the relay circuit is interrupted and the pump motor automatically stops. The motor is not restarted until the level reaches the shorter (upper) electrode, when the aforementioned resistance becomes short-circuited and sufficient current flows to actuate the relay. The relay employed is the Londex *LQA*, the mercury switch of which carries up to 20 amp. at 440 v. Where the liquid is under pressure or insulated electrodes cannot be employed conveniently, a patented automatic liquid level control device of the induction type is available wherein a float is employed to alter the magnetic conditions in two coils which respectively operate the relays at high- and low-liquid levels.

Medical Services in Argentina

IN a recent paper (*Bol. Of. San. Panamer.*, 21, 955; 1942) on this subject, Dr. Hugo J. D'Amato, general secretary of the National Department of Hygiene, Buenos Aires, states that malaria exists in endemic form in northern Argentina and sporadically in the coastal zone. There was a considerable reduction in the number of cases in the endemic area in 1941 when the number of consultations was 193,000 as compared with 231,000 in 1940. More cases of goitre received attention in dispensaries in 1941 than in 1940, there being a high proportion of cases among school-children in the north. The campaign against venereal disease is being actively carried on, as is shown by the fact that the Public Health Department has secured supervision of 717 dispensaries, and serological analysis was being carried out in six cities in 1941. The law for prematrimonial examination is rigorously enforced with excellent results. During 1941, 389 new cases of leprosy were reported, making a total of 4,727, of whom 46 died. In November a colony of 700 beds was added to the existing four institutions under the supervision of the Public Health Department. The number of plague cases (52) in 1941 was a quarter of that for 1940. The following new health agencies have recently been established: a department of specific prophylaxis against diphtheria; a national committee of tuberculosis; a department of hydatidosis, and departments of plague and cancer control. Lastly, strict supervision of drugs has been established.

Public Health in Chile

NO epidemics have occurred in Chile since 1939 apart from some cases of typhus which were immediately controlled (*J. Amer. Med. Assoc.*, October 17). Good results have followed the control of malaria in the northern parts of the country. Although the mortality in early childhood is exceedingly high, much attention has lately been given to the feeding of mothers and infants, whose condition, it is expected, will soon improve. According to a new plan, 3,600 persons will have the right to ask for medical care under insurance as well as 200,000 or more children. Since 1940 the health of the people has been improved by providing rations in public restaurants to poor families free of charge.

Scientific Journal of the Royal College of Science

THE students of the Royal College of Science are to be congratulated on their success in maintaining the publication of their *Scientific Journal*, printing some of the papers read during the session 1941–2 before the Chemical, Natural History and Mathematical and Physical Societies. This volume, the third to be issued in war-time and the twelfth of the series, maintains the high standard and variety of scientific interest of the previous volumes. The range of subjects covers electron diffraction and the electron microscope, graphical and mechanical methods of calculation, the chemistry of hashish and of acetylene alcohols, methane as an engine fuel, the nature of viruses, and luminescence in Crustacea, as well as a historical paper on Arrhenius, Ostwald and van't Hoff. Copies may be bought from the Sales Manager, *Scientific Journal*, Imperial College Union, London, S.W.7 (paper cover 4*s*., bound 5*s*. 6*d*. per copy).

Introduction of Chinese Plants to Great Britain

FEW botanical explorers have surpassed the genius of Ernest Henry Wilson, who introduced the flora of China to Great Britain and North America. A short paper by E. H. M. Cox (*J. Roy. Hort. Soc.*, **67**, Pt. 11, November 1942) describes Wilson's expeditions to China, in the early years of this century, for the firm of James Veitch and Sons and later for the Arnold Arboretum. He visited the provinces of Hupeh and Zechwan, from which he introduced *Davidia involucrata*, *Meconopsis integrifolia* and a very large number of other species. Such well-known garden plants as *Buddleia variabilis magnifica*, *Clematis Armandii*, *Berberis Wilsonæ*, *Thalictrum dipterocarpum* and *Viburnum Davidii*, with several species of Rhododendron, Lilium and Abies, all owe their horticultural introduction to Wilson.

Earthquakes Registered in India during 1940

ACCORDING to seismological bulletins just received, numerous earthquakes were registered at the observatories of Agra, Bombay, Calcutta, Colombo, Dehra Dun, Hyderabad and Kodaikanal during the period July–December 1940 (*Seism. Bull.*, July–Sept. 1940 and Oct.–Dec. 1940. Delhi: Government of India Meteorological Dept.). At Agra, 66 were registered during the period July–September and 75 during the remainder of the year. Again, non-instrumental reports of earthquakes sensible to human beings are an important feature of the reports. During the first quarter under discussion, 16 were reported to J. M. Sil, meteorologist at Poona, the shocks of greatest intensity being of scale 8 (Rossi-Forel) and occurring on August 3 at Gulmarg, on August 8 at Gulmarg, on September 21 at the same place and also at Srinagar. During the second quarter, 11 earthquakes were reported as having been felt, the greatest intensity being 7 on the Rossi-Forel scale on two occasions. The first was at Bhuj on October 31, and the second at Srinagar on December 25.

The Night Sky in February

NEW moon occurs on February 4d. 23h. 29m. U.T. and full moon on February 20d. 05h. 45m. Conjunctions with the moon are as follows: Feb. 2d. 07h., Mars 5° S.; Feb. 3d. 15h., Mercury 0·4° N.; Feb. 6d. 10h., Venus 0·5° S.; Feb. 13d. 01h., Saturn 4° N.; Feb. 16d. 03h., Jupiter 4° N. Occultations of stars brighter than magnitude 6 are as follows: Feb. 12d. 19h. 24·7m., 179 B. Tauri (*D*); Feb. 13d. 19h. 05·6m., 318 B. Tauri (*D*); Feb. 24d. 05h. 00·3m., 65 Virginis (*R*). The times are given for Greenwich, and *D* and *R* refer to disappearance and reappearance, respectively.

There will be a total eclipse of the sun on February 4–5, invisible at Greenwich. The eclipse is visible in Japan, Alaska and the eastern parts of North America. There will be a partial eclipse of the moon on February 20, partly visible at Greenwich. The magnitude of the eclipse is 0·767. The circumstances of the eclipse are as follows:

Moon enters penumbra	....	Feb.	20d.	02h.	43·1m.
,, ,, umbra	....		20	04	03·0
Middle of eclipse	....		20	05	38·0
Moon leaves umbra	....		20	07	13·0
Moon leaves penumbra	....		20	08	32·4

Jupiter and Saturn are well placed for observation during the month. Mercury attains its greatest elongation west on Feb. 18, when it rises at 6h. 15m. in the latitude of Greenwich, about an hour before sunrise. Venus rises about an hour after the sun in the middle of the month and sets at 19h. Mars, in the constellation of Saggitarius, rises at 5h. 30m. about the middle of the month and is not well placed for observation. Comet Whipple is a naked-eye object and can be seen in the night or morning hours up to the time of sunrise. An ephemeris appeared in NATURE of Jan. 23, p. 106.

Announcements

ON the joint recommendation of the presidents of the Royal Society and the Institution of Civil Engineers, the James Alfred Ewing Medal for 1942 has been awarded to Dr. R. E. Stradling. The Ewing Medal is awarded annually for specially meritorious contributions to the science of engineering in the field of research.

THE Council of the Institute of Metals has awarded the Institute's Medal to Dr. Harold Moore, for "outstanding services to non-ferrous metallurgy". Dr. Moore has been director of the British Non-Ferrous Metals Research Association since 1932. Following his training under Dr. J. E. Stead, he held metallurgical posts with industrial firms before joining, as chief metallurgist, the Research Department, Woolwich, of which he was director of metallurgical research during 1919–32. The Institute's Medal, which is offered to the Council of the Institute by the Mond Nickel Company, Ltd., for award annually, is of platinum; previous recipients have been Sir William Bragg, Sir Harold Carpenter, Dr. Pau Merica, Dr. C. H. Desch and Sir W. Murray Morrison. It will be presented to Dr. H. Moore at the annua general meeting to be held in London on March 3.

To commemorate the birth, on March 3, 1843, of the distinguished metallurgist, Sir William Chandler Roberts-Austen, the Institution of Mechanical Engineers, the Iron and Steel Institute and the Institute o Metals have arranged a lecture on his life and work to be given by Dr. S. W. Smith, on Wednesday, March 3, at 5.30 p.m. at the Institution of Mechanica Engineers, Storey's Gate, S.W.1. Sir W. C. Roberts-Austen was an honorary member of the Institution of Mechanical Engineers and he conducted a notable series of researches for the Alloys Research Committee of that Institution; he was a past-president of the Iron and Steel Institute, and his name is perpetuated in the literature of ferrous metallurgy by the word 'austenite'. Dr. Smith, who in 1914 wrote a book "Roberts Austen; a Record of his Work", acted as Sir William's private assistant at the Royal Mint. No tickets are required for the lecture.

X-Ray Evidence of the Nature of Cold Work in Metals

It is well known that the cold working of a ductile metal produces a broadening of its X-ray reflexions, but the physical nature of the changes that produce this broadening does not so far seem to have been satisfactorily established. The broadening may be due to small crystallite size or to the non-uniformity of the lattice parameter, and it is possible that both factors are present in actual practice. Different views, however, are expressed as to which is mainly responsible, and moreover there is a great deal of uncertainty about the real meaning of 'small crystallite size'.

It should be possible to distinguish between the two effects by means of X-rays, for they produce different variations of line-breadth with angle ; if β is the breadth of a reflexion with Bragg angle θ, $\beta\cot\theta$ should be constant for (isotropic) lattice-parameter variations, and $\beta\cos\theta$ should be constant for small (spherical) crystallite size. Dehlinger and Kochendörfer[1] have attempted to find which of these relations is obeyed in the case of rolled copper strip, and concluded that both effects were present ; their methods of estimating broadenings are, however, open to suspicion and their results cannot therefore be accepted unreservedly. Brindley[2] has used filings of various metals, and though he has not corrected his breadths for the broadening due to experimental conditions, he concluded that the non-uniformity of the lattice parameter is the more important effect. According to Wood[3], on the other hand, the main cause of the broadening is the small size of the fragments into which he considers the crystals to be broken by cold work ; but since his results are based mainly on one reflexion they afford no test.

Although filings are not the most suitable subject for experiment, since the stresses in them cannot be known and must certainly be heterogeneous, they form the most suitable kind of specimen for accurate X-ray work. We have therefore attempted to obtain complete evidence of the variation of line-breadth with angle by the methods devised by Jones[4]. Instead, however, of using a standard specimen of 'infinite' particle size, we have taken the photographs in a high-temperature camera of 19 cm. diameter[5], and the standard lines were assumed to be those from the specimen annealed *in situ* and recorded on a separate film. The method is unfortunately least accurate at the low angles, where the distinction between $\cot\theta$ and $\cos\theta$ is greatest ; errors of the order of 30 per cent are possible in the lowest reflexion, 111.

$h\ k\ l$	β uncorrected (mm.)	β corrected (mm.)	θ	$\beta\cos\theta$	$\beta\cot\theta$	E_{hkl} $\left(10^{12}.\ \frac{\text{dynes}}{\text{cm.}^2}\right)$	$E\beta\cot\theta$
1 1 1	0·64	0·18	21·7°	0·17	0·45	1·59	0·72
2 0 0	0·77	0·42	25·2°	0·38	0·89	0·78	0·69
2 2 0	0·84	0·44	37·1°	0·35	0·58	1·26	0·73
3 1 1	1·21	0·76	45·0°	0·54	0·76	1·02	0·78
2 2 2	1·01	0·47	47·6°	0·32	0·43	1·59	0·68
4 0 0	1·65	1·04	58·5°	0·54	0·63	0·78	0·49
3 3 1	2·18	1·24	68·2°	0·46	0·50	1·34	0·67
4 2 0	2·98	1·89	72·3°	0·57	0·60	1·03	0·62

The results for a specimen of copper filings are shown in the accompanying table. The specimen was annealed at 400° C. for 30 minutes to give the standard lines. It will be seen that, although there is a large scatter, $\beta\cot\theta$ has much less systematic variation than $\beta\cos\theta$, which indicates that the broadening is due mainly to lattice parameter variation and not to small particle size. It appears that broadening due to the latter effect, if it exists, is masked by the former.

Whatever the nature of the distortion produced by cold work, it is to be expected that local internal strains will be produced varying between zero and the maximum possible. The maximum possible lattice strain can be calculated from the yield stress Y and the Young's modulus E, and, as shown by van Arkel[6], it agrees well with that observed. From the breadths of the lines in the present case, $Y = \frac{E\beta\cot\theta}{4R} \sim 2 \times 10^9$ dynes/cm.^{2} (where R is the radius of the camera), and the generally accepted value for copper is $1 - 2 \times 10^9$ dynes/cm.^{2}.

Since E varies with direction, we might expect that the breadths of the X-ray reflexions would also vary with direction. The product $E\beta\cot\theta$ should be constant if the maximum stress is independent of direction, and it will be seen that in this quantity, shown in the last column of the table, the scatter of values is much less than for $\beta\cot\theta$ alone. Only one line, (400), is in bad agreement, but this is the weakest line on the film.

Further experiments are in progress. It seems that X-ray methods throw a great deal of light on the mechanism of cold work, but it must be emphasized that the observation of *all* the spectra is necessary if the utmost information is to be obtained.

Ionization in Hydrogen by Fast Hydrogen Neutrals

Recent work by Varney and his collaborators[1,2,3], also earlier work by Beeck[4], have shown that gases can be ionized by their own accelerated neutral molecules or atoms. A classical theoretical treatment of the problem was given by Zwicky[5], who showed that the effect is most likely to occur when both reacting particles are of equal mass. It was first noticed with the inert gases, particularly argon, for which the effect is relatively large. Berry[3] has very recently published results obtained with hydrogen in the type of apparatus developed by Varney's school, in which a velocity selector is used for the positive ions. The latter are neutralized in a separate chamber and then pass into the space-charge detector[6,7], where they are detected after causing ionization. The strength of the remaining neutral beam was assessed by measuring the secondary electron emission from a target by which it was struck. The voltage range for the neutral particles was approximately 900–6,400, and the cross-sections ($N_1\sigma$) per cm.^{3} of gas at 1 mm. mercury pressure were approximately 2(A), 0·05 (He), 0·15 (H_2) and 0·9 (N_2).

I carried out some experiments with a canal-ray positive ion source in 1939[8], using hydrogen (99·3–99·7 per cent, with about 0·7–0·3 per cent oxygen), and which seem to be of interest in view of the above work. The canal ray beam (several hundred microamperes of 20 kV. H_2^+ and H_1^+ ions in approximately equal proportions) passed from the source (about 0·1 mm. mercury pressure), through a canal 2·1 mm. long and 1·5 mm. in diameter, into a region where the pressure was about 5×10^{-4} mm. mercury. The positive ion beam was deflected electrostatically and it was found, as expected from previous work, that a large proportion (about 75 per cent) of the beam, judged by the luminosity in the gas, was composed of neutral particles. The effective strength of the neutral beam was probably several hundred microamperes, and may have reached about 1 milliamp., because, in other experiments, secondary electron currents from various electrodes indicating the possibility of such a beam strength had been measured[9]. A double Faraday cylinder placed to measure the undeflected positive ion beam showed that when the voltage was applied to the deflexion plates, a positive current of about 4 microamp. was indicated. When the source was switched off, leaving the gas flow unaltered, the current always fell to zero, showing the absence of spurious discharges in the deflexion chamber. The main beam was about 18 microamp. in this particular experiment, measured with a small receiving aperture at 50 cm. from the canal, where the strongly divergent beam had, as stated above, a strength of several hundred microamperes. The deflecting field was more than ten times greater than that required to deflect the beam off the collector aperture. On one occasion, 50 kV. was applied to the deflector plates, whereas about 800 volts was sufficient to give adequate deflexion from the collector. Indeed, it is likely that such strong deflecting fields reduce the current of ions to the collector.

It was considered that the residual current might be due either (*a*) to liberation of electrons from the collecting cylinder, or (*b*) to the collection of positive ions produced in the gas by the action of the fast neutrals, if it is reasonable to suppose that such positive ions would tend to be 'knocked-on'. The reaction is:

$$X^{\text{fast}} + X \rightarrow X^{+\text{fast}} + X^{\text{slow}} + e^{-}.$$

Hence the effect was considered comparable in some respects to the well-known *Umladung* reaction

$$X^{+\,\text{slow}} + X^{\text{fast}} \rightarrow X^{+\,\text{fast}} + X^{\text{slow}}.$$

Excitation was also present in the gas, because the neutral beam luminesced (hydrogen red). Case (*a*) was considered unlikely, as the Faraday cylinder was always used in such a way as to eliminate secondary emission effects so far as possible. It was also considered that such emission from the collector could be caused either by reception of fast neutrals or by photons in the gas, although the canal ray spectrum was stated[10] to consist largely of the lines at 4,340, 4,863 and 6,563 A. Further evidence for the absence of secondary emission from the collector was available in that wide variations (1–20 kV.) in the voltage applied to the live (positive) deflector plate had no effect on the magnitude of the residual current. The latter would have been expected to rise with increasing positive deflector plate voltage if the secondary emission from the collector had been taking place. The live plate was made positive to eliminate the effect of secondary emission from it to the earthed vacuum chamber and Faraday cylinder, which was nearly at earth potential. The deflector plates were struck by large stray currents from the canal ray beam.

Thus it seems almost certain, although I wish to emphasize the approximate nature of the results and the fact that no further attempts were made to elucidate the phenomena, that the residual current was due to ionization by fast neutrals, as photoionization in the gas did not seem likely to account for it. Such effects, if present, may also occur in Varney's work. My experiments, described briefly above, were incidental to the main purpose of the work, which was to produce an intense canal-ray beam. However, with the approximate values of pressure, initial neutral beam strength (1 milliamp.) and collected current, the calculated cross-section is of the order given by Berry[3].

In conclusion, it is possible that the copious beams of fast neutrals formed by canal ray sources may be of interest in experimental work of the kind conducted by Varney, who used accelerated electrons from a hot filament to produce the primary positive ions.

Nature of Entropy

To the student of thermodynamics, the conception of entropy usually presents some difficulty. It seems to have no precise physical significance, but is often regarded as no more than a mathematical convention. This can only be due to inadequacy of our thermodynamic theory, since a quantity which fits so completely into the mathematics of the subject must surely have some relation to the physical facts.

The definition of entropy according to the equation $d\varphi = \frac{dQ}{T}$ suggests that it may be regarded as occupying in thermodynamics theory a position somewhat analogous to that of momentum in mechanics, or of coulombs in electrical theory, temperature being analogous to velocity or to electrical potential difference. There ought, in fact, to be such an analogy because, according to the kinetic theory of gases, temperature is proportional to the mean kinetic energy of the molecules; but the analogy fails because of the square law relationship between kinetic energy and velocity, between electrical energy and electrical potential.

Although this, by itself, may seem a flimsy pretext, the suggestion arises that our scale of temperature might with advantage be re-designed so that heat energy should become proportional to the square of temperature. The selection of a scale of temperature based upon equal increments of energy and incidentally equal divisions of a thermometer scale appears to have been rather arbitrary, and is no doubt due to the limited variety of manifestations of heat that can be measured in preconceived terms. In fact, all heat measurements come back to temperature, and that cannot be measured absolutely. It is conceivable that, had we lacked means of measuring velocity directly, we might have evolved a scale of velocity based upon equal increments of kinetic energy.

If, for greater mathematical convenience, we remade our scale of temperature so that temperature became proportional to the square root of heat energy, and, in the kinetic theory, to the mean molecular velocity, then subject to adjustments in the definition of specific heat, the position of entropy would be more clear. Entropy would, in a simple heat transfer, bear a straight-line relationship to temperature, mean molecular velocity would be proportional to temperature, and equal increments of temperature would represent a greater increment of energy at high temperatures than at low. In this and other respects, the theory of thermodynamics would conform more closely to the kinetic theory of gases and would acquire a helpful similarity with mechanical and electrical theories with their basic and, to all intents and purposes, identical energy expressions: $\frac{1}{2}mv^2$ and $\frac{1}{2}CV^2$.

I am not a physicist and do not know the full extent or effect of this tentative suggestion. Einstein said in 1921, "I am convinced that philosophers have had a harmful effect upon the progress of scientific thinking in removing certain fundamental concepts from the domain of empiricism . . . to the intangible heights of the *a priori*".

Is it possible that this is a case in point ?

Reclamation of Bracken-land

IN the course of work on the improvement of rough pasture and moorland, to be published shortly, some attention had to be given to the reclamation of bracken-land. The site (a hillside of the Vardre near the ruins of Deganwy Castle, North Wales) was thickly covered with bracken about 2 ft. in height, free from undergrowth, the soil being sandy to light loam. The following treatment led to satisfactory results.

Late in autumn, the bracken was cut and left spread out on the ground, and a dressing of calcium cyanamide (10 lb. per rod) and manganous sulphate (4 oz. per rod) was applied. Within a few days the vegetation turned blue and gradually withered. In the following March the plot appeared bare, the disintegrated bracken having been embodied in the turfy soil and forming a spongy surface, which readily retained moisture. A mixture of grass seeds, including red and white clover, trefoil, timothy, rye grasses, cocksfoot, tall oat, meadow fescue, crested dogstail, and smooth meadow grass (4 oz. per rod), soil from a pea cultivation (1 lb. per rod) and sand was scattered on to the slimy surface. By the end of June the plot was covered with a fine crop of meadow grass including legumes, the vigorous growth continuing late into autumn. During the next summer the grasses were found well established and free from bracken. Although rational husbandry, such as the addition of phosphorus and potassium, the introduction of grazing cattle and the elimination of bracken in the neighbourhood would have in all probability ensured further improvement and permanency, the plot left unattended amidst an area of bracken gradually receded, and within six years gave all indications of reverting to its original condition.

Here we have calcium cyanamide and its degradation products functioning as an all-embracing parasiticide (cyanogen, urea), humifying agent (ammonia), long- and short-term fertilizer (lime, nitrates), growth promoter (urea)[1], and *p*H regulator (calcium, dicyanodiamide). The humification of all available organic matter, including the bracken rhizomes, is in reality a reproduction of the compost process *in situ*, differing, however, from the Indore method by the preponderance of chemical over biological reactions. The seasonal separation of the destructive from the nutrient phases of calcium cyanamide was attained by increasing its quantity[2] and regulating the time of its application. The manganous sulphate catalyses the oxidation of ammonia to nitrate independently or in conjunction with the nitrifying bacteria[3], reactivated after a lapse of four months. The addition of soil from a pea cultivation, as an inoculation, introduces nitrogen-fixing bacteria essential to the legumes.

This treatment may, therefore, be regarded as an alternative to the methods already in use or suggested in the past. Among such approaches to this problem we have: (1) *burning*, a procedure often impracticable and always wasteful; (2) systematic exhaustive *cutting* handicapped by the labour and time factor; (3) *tillage* (disc or plough), frequently obstructed by steep gradient or rocky subsoil of the area; (4) *injection* of sodium chlorate into bracken stumps, a process catalysed by the addition of vanadium pentoxide[4]; and possibly (5) tillage accompanied by *spraying* with calcium thiocyanate, which gave favourable results in the eradication of nut grass[5]; and (6) the introduction of a suitable *fungus* into the bracken stumps.

There is evidence to show that both during its growth and decay bracken exerts an eliminating effect upon other weeds. Should this be substantiated, it could be made to serve as an intermediate stage in the removal of more resistant and pernicious types, such as bindweeds, etc. This may be correlated with the comparative experiments at Wythenshawe Park, Cheshire, and Holcombe Hill, Lancashire, which have established the discriminating action of calcium cyanamide in so far as its efficiency is dependent upon the type of soil, turf and vegetation.

Water Content of Medusæ; Sexuality in a Planarian

IN recent numbers of NATURE there have appeared two communications which seem to call for comment. In the issue of August 22, Lowndes[1] discusses the question of the water content of medusæ, determining that of *Aurelia aurita* to be 96·56 per cent in sea water of 3·3 per cent salinity. A few years ago I became interested in the same question and also determined the water content of *Aurelia aurita*, finding 96 per cent water in specimens from sea water of 3·2 per cent salinity[2]. Later, I determined the water content of four other species of medusæ, all hydromedusæ, finding 96·5–97 per cent water in specimens taken from sea water of 3·0 per cent salinity[3]. In the first of these papers I reviewed the available data on the subject[4]; these show that in sea water of more than 3 per cent salinity, the water content of medusæ ranges from 94 to 96·5 per cent but that in brackish water of less than 2 per cent salinity, the water content of *Aurelia aurita* may rise to 98 per cent. From these facts it may be inferred that the water content of freshwater medusæ must be very high, and this has recently been found to be the case by Dunham[5], who reports 99–99·3 per cent water in Craspedacusta, thus confirming an old statement by Cremer[6].

IN NATURE of September 19, Goldsmith[7] comments on sexuality in the planarian *Dugesia tigrina* (Girard) 1850 (old name, *Planaria maculata* Leidy). This is the most common freshwater planarian in the United States, occurring throughout the country in ponds, lakes, and streams, and presenting many local and geographic variations. It also occurs, as first noted by Curtis[8], in sexual and asexual strains. In 1937 Kenk attempted to induce sexuality in the sexual forms by various environmental factors, but was unsuccessful[9]. From field data I had noticed that the sexual strain is commonly found in running water or along shores subject to wave action, whereas the asexual strain appears to be confined to ponds and still waters. I therefore suggested[10] that possibly moving water is a factor in the sexual development of this planarian, but shortly after I had published this suggestion I found (unpublished) that this explanation is untenable as regards the sexual strain, and soon Kenk[11] published to the same effect, showing that members of the sexual strain reared throughout life in dishes in the laboratory may become sexual and lay viable capsules. The point raised by Goldsmith had, therefore, already been settled by Kenk. The possibility still remains that there is some relation between permanent asexuality and still water, but this now seems to be unlikely.

The theory of Kenk, which appears to be accepted by Goldsmith, that this planarian has an inherent sexual rhythm is, however, erroneous. In Nature, these worms become sexually mature in early spring and lay cocoons for about three months thereafter. The reproductive system then retrogresses, the copulatory apparatus disappears, and ordinarily there is no further sexual reproduction until the following spring. This cycle is not, however, inherent but is controlled by temperature, as I have shown[12]. The development of the reproductive system, especially of the copulatory apparatus, follows in a few days when the worms are put at room temperature after a sojourn (of two weeks or even less) at a cold temperature (15° C. or below). Stocks brought in from Nature at any time after temperatures have fallen in the autumn and set at room temperature begin to develop sexually in one or two days and start to lay cocoons within a week; although if left outdoors they would not have reached sexual maturity until the following April. Only worms of mature size can be induced to mature sexually by temperature change, and some time must elapse (about three or four months) before sexuality can again be induced in the same individual by manipulation of the temperature.

Seed Dispersal by Human Activity

IN a recent paper[1] dealing with weed problems, Prof. E. J. Salisbury has directed attention to accidental carriage and distribution of seeds by human activity, and instances that clothes can be one of a number of means of distribution.

In recent research work on tussock grassland in North Canterbury, New Zealand, with particular reference to the distribution of the nassella tussock (*Nassella trichotoma* (Nees) Hack.), it was demonstrated that clothing can be an important means of seed distribution. The 'cuffs' of a pair of trousers yielded some 17 gm. of seeds and fruits (after five days' field work), the mixture being composed of the seeds and fruits of 33 species of plants, 19 species of grasses, and the remainder of other weeds. Several pairs of socks yielded, among other germinules, more than three hundred 'seeds' of nassella tussock, a troublesome plant rapidly becoming locally dominant in North Canterbury.

The relatively large amount of seeds and fruits present, the number of species and genera represented and the quantity of each, indicated the potentialities of this little-considered means in the distribution of plants, both noxious and beneficial.

RESEARCH ITEMS

nsects of Norfolk Island

In the December issue of the *Annals and Magazine* *f Natural History* (9, No. 60, 865; 1942) the insect auna of Norfolk Island is discussed by C. N. Hawkins. he account also includes a preliminary report on a ecent collection of insects from that same area. The uthor considers that, generally speaking, the insects f this somewhat remote island would repay much nore intensive collecting and investigation. The ruly endemic species have been extensively supplenented by introductions from other lands through uman agencies. It appears, therefore, necessary to e very careful in drawing inferences from the present auna and to exclude all species which could have een artificially introduced at a time when little ttention was given to such matters. Allowing, herefore, for such immigrants, it does appear that in he main the insect fauna of this island shows more ffinity with that of North-Eastern and Eastern ustralia than with the New Zealand fauna, although here is undoubtedly some connexion with the latter lso. In discussing a recent collection of insects from orfolk Island the author states that it comprises hirty-three species of Lepidoptera, of which only leven are mentioned in earlier lists by various riters. The Coleoptera are distributed among ighteen families and number thirty-eight or more pecies. The Hymenoptera include a number of pecies of ants and parasitic forms. No Apoidea are nentioned and only two species of Vespoidea and ne of Sphecoidea are recorded. Of the Hemiptera, xcluding the Coccidæ, Aphidæ and Aleurodidæ, only hirteen species are listed. The Diptera have not, so ar, been worked out. A special feature of the collection, as a whole, is the considerable number of pecies of wide distribution and general economic mportance that it contains.

nique Freshwater Crustacea

The rivers of temperate South America are inabited by a unique genus and family of fresh-water rustaceans found nowhere else in the world. When atreille in 1818 described a new species as *Galathea evis* he was unaware that it was a freshwater form nd placed it in an exclusively marine genus. Two ears later Leach noticed that it was a representative f a new species but was also worthy of being placed a new genus which he termed Aegla. Since that ime it has been recorded from a number of different calities and is indeed widespread, and several different specific names have been given. The general sage, however, has been to regard all the records as elating to one species, which has been termed *Aeglea evis*, after an incorrect spelling of the generic name troduced by Demarest in 1825. Waldo L. Schmidt *Proc. U.S. Nat. Mus.*, **91**; 1942) has, after the examation of practically all the material available (now uite considerable), provided a detailed and well lustrated review of the genus. He recognizes ighteen distinct species and of two of them a marked ariety. The distribution of the various species is ealt with, and it is noted that a number of them ppear to be confined to the individual watersheds f large tributaries in somewhat the same manner s the limitation of certain molluscan species to ifferent valleys. The Æglidæ appear to be most losely related to the Galatheidæ, and so furnish n example of another crustacean family invading esh water.

Proliferation-promoting Substances from Injured Cells

Observations which suggest that factors, active in promoting proliferation of cells, appear in the intercellular fluids when yeast or animal tissue cells are injured, without rupture of cell membranes, by such agents as ultra-violet rays are: (1) slow injury to cells leads to higher potencies of intercellular fluids than rapid killing; (2) the potency of the fluids increases rapidly before appreciable mortality is noted; (3) the potency is greater when cells are injured in a physiologically favourable suspension medium; (4) active factors appear in suspensions of cells subjected to anærobiosis without killing the cells; and (5) cells killed quickly by grinding and boiling and then subjected to injurious rays yield less potent preparations than cells injured slowly by irradiation prior to quick killing by grinding or boiling. J. R. Loofbourow (*Biochem. J.*, 36, 631; 1942), continuing these studies, suspended *S. cerevisiæ* in distilled water and subjected the cells to injury by ultra-violet irradiation. He found no appreciable change in cell number throughout the irradiation period, which, together with the absence of cytolysis, indicated that the proliferation-promoting factors in the intercellular fluids were released through the membranes of grossly intact cells. Preliminary studies with radioactive phosphorus indicated an increase in membrane permeability during irradiation. Resynthesis of growth-stimulating materials occurred in the living, damaged cells at a rate comparable with the loss of such materials to the intercellular fluids. Of monochromatic wave-bands, that at 2650 A. was the most effective in bringing about the release of proliferation-promoting factors, cell death, loss of cell volume and increase in 2600 A. absorption of the intercellular fluids. There is indicated a correlation between the lethal effectiveness of various wave-bands and their ability to bring about the release of these factors.

Anatomy of Leguminous Root Nodules

Miss Helen L. Frazer's observations upon this subject (*Proc. Roy. Soc., Edin.*, 61, B, Part III (No. 24), 1942) give more precision to our knowledge of the distribution and structure of the endodermal boundaries to be found within these nodular tissues from an early stage in development. They were studied in various common leguminous plants and in all cases (except in some large specimens from lupin) were characterized by the presence of a common endodermis in the outer tissue, in addition to individual endodermal sheaths around each vascular strand. The cells of the common endodermis had a complete suberized lamella from an early stage, and experiments with dyes confirm the natural conclusion that the nodular contents must thus be retained within the nodule even if soluble and free to diffuse from the infected tissues. On the other hand, in the elongate form of the nodules, suberization progressed slowly towards the distal end of the endodermal sheaths around each vascular strand, so that movement of solutes to or from the vascular strand should remain possible in this region and possibly also through the occasional unsuberized (? passage) cells found in the bundle endodermis in the spherical type of nodule. The impermeability of the common endodermis may lead to a reduced air supply in the inner tissues, a condition that has been assumed by some other workers as an inference from the study of nodule respiration.

Eye-Spot of Wheat and Barley

Two recent papers by Miss Mary D. Glynne describe the disease eye-spot, caused by the fungus *Cercosporella herpotrichoides* (*Agriculture*, 49, 2 ; Sept. 1942). It causes a rather destructive type of lodging in wheat crops, and is aggravated by too great a frequency of wheat and barley in the rotation. Oval, brown-bordered spots, shaped rather like an eye, appear on young plants, and black dots later form in the middle of the eye-spots. The disease penetrates successive leaf sheaths, and bad infections weaken the straw. A useful survey of the incidence of the malady (*Ann. Appl. Biol.*, 29, 3, 254 ; Aug. 1942) shows that the disease is more prevalent in eastern England than in North Wales, and reinforces the conclusion that the greater the time after the previous cereal crop, the lower the chance of severe infection.

Californian Sequoias

A STUDY by Looby and Doyle (*Sci. Proc. Roy. Dublin Soc.*, 23, 35–54 ; 1942) of the origin of the gynospore and development of the female gametophyte in *Sequoia gigantea* and *S. sempervirens* shows that marked differences obtain in the number of gynospore mother-cells produced, the form of the spore tetrads, the origin and duration of the tapetum, the growth of the nucellus, the segmentation of the young gametophyte and in alveolar formation. These differences strongly support the recent suggestion of Buchholz, based on post-fertilization and other studies, that the two Californian Redwoods are generically distinct. The name *Sequoia sempervirens* is retained for the redwood while the 'Big Tree' or Sierra redwood reverts to its former title of *Wellingtonia gigantea*.

Recording Plastometer for Organic Plastics

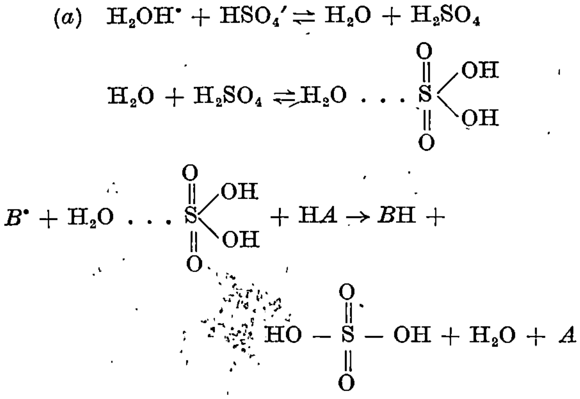
AN article (*Bell Lab. Rec.*, 21, No. 1 ; September 1942) by F. J. Biondi describes an improved parallel-plate plastometer, used to measure the flow properties of plastics, which has recently been developed by the Laboratories to plot automatically the relation between the variables measured. A specimen of the material is deformed by a known force at a specified temperature and the decrease in its height with time is magnified and recorded. The plastometer has two horizontal plates which press between them a small cylindrical pellet of the plastic material. An electrically heated and thermostatically controlled steel block surrounds the specimen, while the frame which supports this block also carries bearings for a shaft connected to the upper plate. A weight, supported by the upper end of the shaft, which is also connected by a universal link to the multiplying and recording apparatus, deforms the specimen. A series of levers and pulleys multiplies the movement between the plates approximately thirty times. This multiplying mechanism and that which drives the paper on which the record is made are housed in a cabinet at the top of the machine. Below the plastometer are the temperature regulating equipment, voltage control and auxiliary switches. An electronic regulator controls the temperature of the steel block within narrow limits from room temperature up to 300° C. Flow curves show that flow occurs more rapidly as the moisture content of the pellets increases, and that in a particular material the average rate of flow can be nearly doubled by changing the moisture content of the pellet two per cent. Moisture is one of the variables which must be measured and controlled if powder of constant flow characteristics is to be supplied to moulding machines. The recording plastometer has also been used by the Laboratories to measure the individual and combined effects of the other variables which affect the flow of plastics.

The System Ethanol-Methanol at 40°

THE system $C_2H_5OH-CH_3OH$ has been studied, from the point of view of vapour pressure, by A. C. Morris, L. T. Munn and G. Anderson (*Canad. J. Res.*, 20, 207 ; 1942). The total-pressure curve plotted against mols per cent is linear, and the partial-pressure curves agree with Raoult's law within the experimental error. This is an interesting result, as both alcohols are generally regarded as 'associated' liquids, and still the system closely approaches an 'ideal' one. Attention is directed to the difficulty of purifying the alcohols, particularly from water, and it is clear that the density is not a 'sufficient criterion' of purity, although in general use for this purpose.

Heavy Oxygen

USING heavy oxygen (^{18}O) water having an excess density of 150–210 γd, E. R. S. Winter and H. V. A. Briscoe (*J. Chem. Soc.*, 631 ; 1942) have studied the exchange of oxygen between water and oxyacid radicals, with special reference to the sulphate and bisulphate ion. Contrary to previous findings, $KHSO_4$ and KH_2PO_4 interchange, though slowly, at 100°. In certain cases the effect of addition of other salts and free acid was examined. The rate of interchange in bisulphate solutions increases with concentration and temperature ; the cation has a marked influence, the interchange being substantially greater with the sodium than with the potassium salt ; and the addition of other (inert) salts or of free acid also increases the rate. The rate is substantially lower for KH_2PO_4 as compared with $KHSO_4$. Although no simple mechanism will satisfactorily explain the experimental figures, it is concluded that the most probable explanation is that interchange occurs through anhydride formation, and this applies to KH_2PO_4 at 100° and K_2CrO_4 at 20°. The mechanism for $KHSO_4$, for example, is either



$$(a)\quad H_2OH^{\cdot} + HSO_4{}' \rightleftharpoons H_2O + H_2SO_4$$

$$H_2O + H_2SO_4 \rightleftharpoons H_2O \;.\;.\;.\; S(=O)_2(OH)_2$$

$$B^{\cdot} + H_2O \;.\;.\;.\; S(=O)_2(OH)_2 + HA \rightarrow BH + HO-S(=O)_2-OH + H_2O + A$$

(where $B^{\cdot}$ and A' are Brönsted base and acid respectively)

$$\text{or } (b)\quad H_2OH^{\cdot} + HSO_4{}' \rightleftharpoons H_2O + H_2SO_4$$
$$H_2SO_4 \rightleftharpoons H_2O + SO_3.$$

Scheme (*b*) is, as stated, preferred.

AGRICULTURAL EDUCATION IN GREAT BRITAIN

AGRICULTURAL education in rural areas of Great Britain was the first subject for discussion at the recent conference of the Agricultural Education Association held at the Midland Agricultural College during January 4–6.

Mr. F. H. Garner prefaced his remarks by saying that the inhabitants of the countryside who are of necessity interested in agriculture are the landowner, the farmer, the farm worker and the parents of children living in the country. Little special effort has been made to educate landowners, but to a very large extent they have received information on all phases of agriculture. The older type of landlord is being replaced by a new type, such as the universities, colleges and insurance companies; the agents who manage such estates have had good training in agriculture and the results are good from the farmer's point of view.

As regards the farmers, the county councils, through the agricultural organizers and their staffs, are in the first instance primarily responsible for their education. A certain amount of work has been done by the National Farmers' Union, agricultural societies and clubs, and so on. A certain percentage of farmers have taken courses in agriculture at the universities, agricultural colleges and institutes. About two years after the outbreak of war, the War Agricultural Executive Committees took over much of the educational work in agriculture through their technical development sub-committees, and in many cases the work was carried out on a much wider scale than had been possible hitherto. These sub-committees could be very active because money was made available for educational work; they were helped by the fact that farmers were getting better prices and consequently could try out recommendations. They have done more to push forward the education of backward farmers than has ever been accomplished before, and it seems most important that such work should be maintained in peace-time. During the last few years, an agricultural bias has been introduced into he teaching at many rural schools, and the Young Farmers' Club movement is extending rapidly; it can be stated that in various ways farmers are eceiving an agricultural education.

On the other hand, there has been very little attempt to provide agricultural education or instruction for farm workers. There have been a few short ourses at agricultural institutes, but generally farm workers have received very little education in rural matters. More recently, but only to a limited extent, ome of the demonstrations run by the War Agricultural Committees have been staged to attract the gricultural worker. Sometimes the workers show no inclination to attend the demonstrations, and there is the added difficulty that these workers, having to arn their livings on the land, are unable to attend if loss of wages results, except perhaps on Saturday fternoons. Demonstrations must be specially lanned for the workers, and farmers must be pproached in order that they may encourage their men to attend. Also, the farm institute courses for he young farm worker must be reintroduced, and his despite the danger that after these young people ave attended their courses they may try to leave he land and obtain more remunerative posts.

With regard to the parents of the country school children: these parents may have various interests, for they may not all be agricultural workers. In the past, this section of the community has received no agricultural education of any kind, and it is quite evident that parents can undo all the good work done by schools, Young Farmers' Clubs, county councils, etc., in maintaining interest in rural activities. Before parents will encourage their children to work on farms they must first be satisfied that housing in rural areas is as good as it is in towns, and that their children can find adequate recreation, both indoors and outdoors, in the villages; that their children will earn as much money on the land as in the town; and that agricultural work is not degrading. Something must also be done to appeal to wives and prospective wives of the farm worker. The courses given in rural schools on domestic science, dressmaking and hygiene are very valuable, but if the girls find that housing conditions in rural areas make it difficult, and sometimes impossible, for them to do as they have been taught, they may be forced, through education, to find houses in the towns.

The ensuing discussion had a very wide range, for several speakers felt that in the matter of agriculture it is not possible to separate rural from urban education. Mr. S. J. Travers, of Kent, believes that urban and rural children should be educated together: they would be on the right lines if they could be made to understand that the land is a national asset and not to be abused as it had been in the past. It was pointed out by Mr. R. H. Smith, Hampshire, that whereas the rural child, through scholarships, etc., has the beginning of a ladder, the urban child has no means at all of obtaining the first steps in agricultural education. Town boys who are eager to take up agriculture may have their enthusiasm killed by being placed in unsuitable work on unsuitable farms. Other speakers also mentioned this question of a 'ladder'. Principal Robinson, Midland Agricultural College, referred to the need for an agricultural education which would give encouragement to the man with ability but lacking the capital to advance up the ladder. He thought a rural bias could well be introduced into education, not so that plenty of skilled labour would be available for the farmer, but to enable even the town boy or girl to appreciate and understand countryside problems. The cry in the past has been cheap food and hang the farmer: unless we educate the rural with the non-rural community, we shall not achieve this appreciation.

The opinion that teachers generally should be educated to the importance of agriculture as an industry was voiced by Mr. W. R. Heaton, Burford Grammar School, who complained that very little financial support is forthcoming for any scheme in agricultural education. He stressed that vocational agriculture should not be taught in schools, but instruction should be given in the underlying fundamentals of biology, chemistry of soils, and some book-keeping and mathematics done from mensuration of farm buildings, etc.

After several members had contributed to the discussion, Mr. John Davies, Glamorgan, remarked that the scope was for ever widening as each speaker seemed anxious to educate yet another class of people. He then asked: Whom do we wish to educate? He believed that the farmer and the farming community are entitled to first consideration, and this opinion was warmly supported by Mr. A. McVicar, Shropshire, and Mr. E. Rea. Mr. McVicar and others said that there is no recognized plan or scheme for a system of agricultural education in Great Britain, and this is urgently needed. It was suggested by Mr. F. R. Horne, of Devon, that not enough attention has been paid to following up the careers of the more promising trainees to see that they become established in agriculture.

The technical development sub-committees referred to in Mr. Garner's paper were both criticized and praised. They were spoken of as an implied criticism of pre-war policy in agricultural education, because if this had not been neglected in pre-war years, there would not now be the necessity for forming these committees. The work of these committees was also stated not to be fundamental education but rather 'tip-giving'. On the other hand, the expansion of agricultural education through the committees *as a national charge* was welcomed, and it was urged that if they are to continue after the War they must be moulded on the right lines now.

A statement by Mr. R. C. Andrew on the Danish system of education for older people caused Mr. R. C. Wood to urge his hearers to familiarize themselves with the writings of Sir Richard Livingstone on the Danish folk high schools. More attention must be paid to adult education and a more cultural atmosphere should be introduced into agricultural institutions in Great Britain.

NORTH SYRIA AS A CULTURAL LINK IN THE ANCIENT WORLD

THE subject chosen by Sir Leonard Woolley for his Huxley Memorial Lecture delivered on November 24 before the Royal Anthropological Institute was the role played by north-west Syria in the first and second millennia B.C. as a connecting link between the civilizations of the Near and Middle East. The region is defined as the area stretching from Lattakia on the present north Syrian coast northwards to the Anti-Taurus Range, and from the Mediterranean Sea to Aleppo. To the south and south-east lay "the commercial kingdoms of Syria and the Phœnician harbours", with Egypt still farther to the south; eastwards lay the homes of the Amorites and the Khurri, leading on to Nineveh. The Euphrates leads direct to Babylon or north-eastwards to the region of Lake Van and the Uratu kingdom; northwards beyond the mountain barriers lay Cappadocia and the Konia plain, leading to the Bosphorus or the Ionian coast; westwards were Crete and Greece, with Cyprus—actually visible from the top of Mount Casius—as a stepping-stone. The nodal position of the region thus chosen is obvious.

Before the War, three main excavations of special interest from Sir Leonard's point of view were in progress: Ras Shamra, just north of Lattakia, the ancient royal city of Ugarit; Al Mina, at the mouth of the Orontes, and the Atchana mound, up the Orontes on the edge of the great Amk plain; and Tal Tayanat, where the Oriental Institute of Chicago has excavated the Syro-Hittite palace. Other recent excavations there have of course been in the Amk plain, and also farther north-westwards as at Mersin on the Cilician coast, but Sir Leonard in the limited time available confined himself principally to the results of his own work at Atchana where, too, the chronological framework devised by Prof. Sidney Smith in his monograph "Alalakh and Chronology" provided him with a gratefully accepted method o correlation with better known cultures in neighbouring lands.

At Alalakh (the Atchana mound) there were unearthed seven archæological levels of buildings pottery, etc., and a trial pit has shown at least three more underneath and as yet unexcavated. Layer 7 has yielded an imposing city gate and a great palace built by Yarim Lim, king of Aleppo and overlord o Alalakh—according to Sidney Smith *c.* 1780–1730 B.C It is contemporary, therefore, with the end of the Egyptian Twelfth Dynasty and the Middle Minoan period of Crete. Near the coast at Ras Shamra Middle Minoan II sherds have been discovered in presumably contemporary levels but, of course, this does not itself prove *direct* contacts. No Cretan ware occurred at Alalakh; all was Asiatic (Khabur ware) and the types persisted down to level 5, *c.* 1483 B.C During 1800–1500 B.C. Alalakh was thus predominantly Amorite. There is evidence (seal-impressions that Egyptian political claims were recognized, bu culturally the town looked eastwards. But while the influence of the West on Alalakh seems at this time to have been slight, Sir Leonard feels that the astonishing resemblance of the palace itself in its plan and construction to that of Knossos, not to mention the style of the frescoes found, suggests, even as Sir Arthur Evans hinted ("Palace of Minos", 2, 269 that migration of Asiatic people to Crete played a part in the rise of the culture there. He adds tha the frescoes at Alalakh are at least a century older than their parallels at Knossos, so that "there can be little doubt as to the originating centre", and argues that North Syria was helping to build up in Crete that remarkable Minoan civilization which wa later to have its repercussions in Asia. In the same way and on the same grounds of architectural resemblances, he suggests that Amorite influenc affected the regions to the north, inspiring not only the late Syro-Hittite buildings of North Syria such as Sakje-Geuzi and Carchemish, but even the mor distant Boghaz Keui in the Halys basin.

In levels 6 and 5 there are fewer remains. It would seem that the influence of Egypt disappeared—thi was the period of the Hyksos domination there—bu the Hittites to the north were becoming an organize power. It was a Hittite invasion of North Syria conducted by Mursil I in 1595, that terminated th local phase represented by level 6. However, culturally Alalakh continued much as before unt Thutmose III conquered the town in 1483. But th weakness of Egypt permitted the folk of the 6t level to be in closer relationship with southern Syri and Palestine, as is reflected in the types of potter found.

Level 4, starting from the Egyptian campaign o 1483, comprises, in so far as its principal building i concerned, three phases, including the enlarge palace of Niqme-Pa, *c.* 1450, which take us down t 1370, when the Hittite king Suppiluliuma invade North Syria and, after destroying the Mitanni kingdom installed his son as king of Aleppo. The main featur of the pottery of level 4 is the prevalence of th Cypriote Bronze Age type. Gone is the old Khabu ware. The better local wares are now either plai burnished red, or have simple bands of colour. All hav a distinctly Cypriote flavour. As the typical Cypriot 'milk bowl' actually occurs at Alalakh so early a level 6 (seventeenth century B.C.) and sherds resembling the Cypriote white slip ware have bee earthed from below level 7, once again Sir Leonard ncludes that, throughout, the main influences wed from the mainland to Cyprus and not vice rsa. To this level, too, must be ascribed certain ulptures of Hittite type which were actually found, -used, in level 1. Sir Leonard sees in these the rect forerunners of the lions of early type at rchemish and of the watergate reliefs of the same ty. His argument is further supported by the nding of a bronze lion dagger, almost an exact rallel to the 'dagger god' represented in the asilikaya rock carvings. Niqme-Pa's palace has pplied one example of Lower Minoan II pottery, d another contemporary one with the familiar topus pattern found in a private house. Ivory rvings, which are clearly copies of Egyptian proto- pes of the time of Thutmose IV, occur, and ntact with Egypt at this time seems to have been ose.

The buildings of level 3 are few and poor. The riod begins with Suppiluliuma's conquest of North yria and lasts until 1285 B.C. Throughout this time lalakh was ruled by the Anatolian Hittites, which ct explains the difference at this period between it d Ugarit (Ras Shamra), which was only fifty miles way, for the latter did not fall under Hittite control. he influx of Ægean settlers and others made of the yrian coast town an outpost of Late Minoan II vilization, but only a very little Ægean influence n be noted at Alalakh.

Level 2 is dated from about 1275 to 1220 B.C. The ain interest here is the occurrence of a local Syrian litanni) ware, the decoration of which is ornate ith bold rosettes in white on a dark ground and imal and bird forms introduced. A development this, apparently peculiar to Alalakh, has all-over signs in which the motifs are running water, aborate stylized lotus plants, and the double axe. he connexion with the Cretan Middle Minoan III indisputable, though no doubt an example of ferred inspiration.

With the fall of the Hittite power in 1220 B.C., lalakh was more open to Ægean influences. Nearly ery grave in Level 1 contains a Mycenæan vase, d doubtless Ugarit was the connecting link. Then me the great movement of the 'Peoples of the Sea' ho swept down, about 1190 B.C., through Anatolia d Syria and were only stopped by Ramses III on e borders of Egypt itself. Ugarit was destroyed, as as Alalakh, and neither site was ever again re- cupied.

To sum up, Sir Leonard Woolley considers that ere is evidence for :

(1) "Direct contact with the Asiatic mainland nfluencing in or before the 18th century the develop- ent of the Cretan civilization."

(2) The existence in the Anatolian Hittite con- deracy of an important element culturally if not cially akin to the Amorite population of northern yria.

(3) A possible Asiatic origin of the Cyprus Bronze ge culture.

(4) Egyptian control of northern Syria in the welfth Dynasty with, later, a relation between the yksos culture and that of the Amk plain.

(5) Direct Late Minoan II and III influences on orthern Syria.

(6) The development of Syro-Hittite art in northern yria long before the beginning of the Syro-Hittite olitical period and of its kinship with the Hittite rt of Anatolia.

ASSOCIATION OF SCIENTIFIC WORKERS

MEDICAL SCIENCES COMMITTEE

AT a conference for workers in the medical sciences arranged by the Association of Scientific Workers, held on January 9 at the London School of Hygiene and Tropical Medicine, Dr. D. McClean (chairman) recalled that the Medical Sciences Committee of the Association was elected in May, 1942, in an attempt to put into operation the policy of the Association in the medical sciences. That policy was the application of science for the benefit of the community and the raising of the status of the scientific worker. The responsibility for the application of medical science to public needs lies with medical scientists (not medical men alone) themselves; means should therefore be provided whereby all medical scientists could consult on methods of improving their work and collaborate in the most effective way in pressing for its application in practice.

Mr. Ben Smith, industrial organizer of the Association of Scientific Workers, emphasized the necessity for organization of workers in the medical sciences if they wish to get their policies implemented. Any activity the object of which is to alter existing conditions is necessarily political in nature, and for political activity organization is essential.

Dr. J. H. Humphrey, speaking for the Industrial Health Sub-committee of the Association, said that owing to the increasing numbers of persons working in factories and the extreme specialization in the work, industrial hazards are becoming more complex and important, while the medical personnel available for their prevention and the treatment of their effects are inadequate. Work on industrial hazards was carried out before the War by the Industrial Health Research Board; during the War, the activities of this body have practically ceased, but partly owing to the efforts of the Association it has recently been resuscitated. The Physiological Society has circularized its members to discover whether physiologists are available for full-time or part-time work on industrial health problems. None were available for full-time work, few for part-time. Liaison with shop stewards has also proved very profitable, as workmen themselves have suggested problems for medical research which might otherwise have passed unnoticed. The main difficulty is less to obtain new knowledge than to get what is already well-known applied.

Dr. Yudkin directed attention to the unorganized nature of nutritional research and gave an account of the efforts of the Nutrition Sub-committee of the Association to obtain co-ordination of nutritional research by pressing for the formation of a Nutrition Council.

Dr. C. L. Oakley spoke on the difficulties experienced by research workers in discovering who are working in their own and closely related fields; ignorance of current and unpublished research leads to much duplication of work and waste of time and energy. The specialization of modern research work frequently requires collaboration between experts in various different techniques. Those who wished to collaborate should be encouraged, and for this purpose he suggested the formation of a central bureau at which research work could be registered in title, and from which information could be sent out to workers in the same or closely related fields. The most natural body to undertake this work might appear to be the Central Register, since it already possesses the names of all active research workers. Nevertheless, it was pointed out that departmental demarcation within the Civil Service might produce obstacles. He emphasized that the Bureau would exist only for collaboration, not for the staking out of claims in special fields of research. Interested bodies are being circularized to obtain support for this scheme.

Mr. Griffin suggested that the present lack of status of laboratory technicians should be remedied by the introduction of a full course of training for them, followed by a qualifying examination; successful candidates to be enrolled in a State register. To effect this it would be essential to have large numbers of technicians in an organization such as the Association of Scientific Workers, which can undertake trade union activity.

Mr. A. L. Bacharach said that for much biological experimental work animals are as essential as pure chemicals are to the chemist. Of the many thousands of animals of many different species so used, a small percentage only are bred for the purpose; the rest are obtained from dealers. Since the suitability of animals for experimental purposes depends almost entirely on their genetic make-up, their freedom from disease and their diet—subjects on which almost all dealers are lamentably deficient—it is not surprising that a large proportion of dealers' animals are unsatisfactory. Besides this, the demand for animals far exceeds the supply. Adequate supplies of pure-bred, healthy, well-fed laboratory animals could be obtained only by tackling the problem on a national scale, by the development of Government-controlled breeding centres. A scheme for the development of such centres circulated to learned societies and users has received sufficient support to justify asking the Medical and Agricultural Research Councils and Ministry of Supply to receive a joint deputation of interested parties.

Two resolutions were adopted by the meeting: the first urged the Ministry of Health to secure the compulsory pasteurization of all milk for human consumption, and to take necessary steps to secure the requisite equipment and to reserve adequate skilled personnel; and the second welcomed the setting up of the Allies' Post-War Requirements Bureau, promised full co-operation of the Association on scientific matters, and expressed the hope that the work of the Bureau includes the preparation of relief immediately following Allied intervention on the European continent.

FORTHCOMING EVENTS

(Meetings marked with an asterisk are open to the public)

Saturday, January 30—Sunday, January 31

Association of Scientific Workers (at Caxton Hall, Westminster, London, S.W.1). Conference on "Planning of Science in War and in Peace" (to be opened by Sir Robert Watson-Watt, F.R.S.).*

Saturday

At 2.30 p.m.: "The Central Direction of Science".

Sunday

At 10 a.m.: "Local Organisation".

At 2.30 p.m.: "Determining the Future".

Saturday, January 30

Society of Chemical Industry (in the Chemistry Lecture Theat of the University of Sheffield, Western Bank, Sheffield), at 2.30 p.m. Dr. W. H. J. Vernon: "The Corrosion of Metals in Air" (Jubil Memorial Lecture).

Monday, February 1

Royal Society of Arts (at John Adam Street, Adelphi, Londo W.C.2), at 1.45 p.m.—Dr. P. Dunsheath: "Industrial Research Great Britain, a Policy for the Future" (Llewelyn B. Atk'ns Memorial Lecture).

Institution of Electrical Engineers (at Savoy Place, Victor Embankment, London, W.C.2), at 7 p.m.—Prof. C. L. Fortescu "The Relation between Subsequent Career and the Form of Pr liminary Training".

Tuesday, February 2

Institution of Civil Engineers (Structural and Buildin Engineering Division) (at Great George Street, Westminste London, S.W.1), at 2 p.m.—The Rt. Hon. Viscount Falmouth: "Rece Developments in Fire Research and Fire Protection Problems".

Royal Institution (at 21 Albemarle Street, London, W.1), 3 p.m.—Sir Lawrence Bragg, F.R.S.: "The Solid State", (ii) "Plu minus Compounds".*

Wednesday, February 3

Royal Society of Arts (at John Adam Street, Adelphi, Londo W.C.2), at 1.45 p.m.—Mr. G. H. Bates: "Agriculture To-day an To-morrow", 4: "Maintaining the Ploughed-up Area after the War

Institute of Physics (Electronics Group) (in the Lectu Theatre of the Royal Institution, 21 Albemarle Street, London, W. at 5.30 p.m.—Discussion on "Dielectric Breakdown and other Ele tronic Processes in Solids" (to be opened by Dr. H. Fröhlich).

Institution of Electrical Engineers (Wireless Section) (Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m. Prof. Willis Jackson: "The University Education and Industri Training of Telecommunication Engineers".

Institute of Welding (at the Institution of Mechanical Engineer Storey's Gate, St. James's Park, London, S.W.1), at 6 p.m.—A seri of papers on "Developments in Arc Welding Technique".

Thursday, February 4

Institution of Civil Engineers (at Great George Street, Wes minster, London, S.W.1), at 2.30 p.m.—Fifth (final) Discussion Mee ing: "Civil Engineers and the Building Industry—Management an Organization; the Future of the Building Industry" (to be open by Lord Reith).

Friday, February 5

Royal Society of Arts (India and Burma Section) (at Joh Adam Street, Adelphi, London, W.C.2), at 1.45 p.m.—Colonel S Samuel Christophers, Bart., F.R.S.: "Measures for the Control Malaria in India".

Royal Institution (at 21 Albemarle Street, London, W.1), at 5 p. —Prof. J. C. Drummond: "History and Knowledge of Scurvy an its Treatment".

Saturday, February 6

Nutrition Society (at the London School of Hygiene and Tropic Medicine, Keppel Street, London, W.C.1), at 11 a.m.—Conference "Nutrition in Pregnancy".

British Rheologists' Club (at the Royal Society of Arts, Joh Adam Street, Adelphi, London, W.C.2), at 2.15 p.m.—Dr. R. Haward: "The Extension and Impact Resistance of some Plast Materials".

Geologists' Association (at the Geological Society, Burlingto House, Piccadilly, London, W.1), at 2.30 p.m.—Mr. F. A. Banniste "The Determination of Minerals by X-Ray Methods".

APPOINTMENTS VACANT

Applications are invited for the following appointments on before the dates mentioned:

Gas Examiner (part-time) for tests at Uxbridge and Hampto Court Gas Works—Mr. C. W. Radcliffe, "R.2", Clerk of the Count Council, Middlesex Guildhall, Westminster, London, S.W.1 (endors 'Gas Examiner') (February 3).

Lecturer in Mathematics—The Principal, Dudley and Staffor shire Technical College, Dudley (February 4).

Director of the Gas Research Board of the Gas Industry The Secretary, Gas Research Board, Gas Industry House, 1 Grosven Place, London, S.W.1 (February 22).

Master for Engineering—The Headmaster, The Gateway Schoo Leicester.

Lecturer in Engineering (Mechanical)—The Principal, Nort Staffordshire Technical College, Victoria Road, Stoke-on-Trent.

Master or Mistress to teach Physics—The Headmaster, Dove College, Poltimore, Exeter.

Lecturer in Biology, mainly for Botany—The Registra Municipal College, Portsmouth.

Air Ministry, Assistant Mechanical and Electrical En gineers for the Provinces—The Ministry of Labour and Nation Service, Central (Technical and Scientific) Register, Section D.31 Sardinia Street, Kingsway, London, W.C.2.

UNIVERSITIES AND RECONSTRUCTION

THE address which Mr. Archibald MacLeish, director of the Office of Facts and Figures, delivered before the American Library Association on June 26, 1942, and which has been included in an admirable "America faces the War" pamphlet (No. 16. Total War and the People's Peace. Oxford University Press. 6*d.* net), directs attention to some very important issues. That the whole Nazi regime is an attack on the scholar's world with its freedom of thought, of investigation and of utterance, was realized by many in Great Britain long before the outbreak of armed conflict. Intellectuals generally have now learnt that their world is in real and present danger, but it is not yet appreciated everywhere that it can be saved only by courageous and unrelenting attack.

In the world of science, growing co-operation between British and American workers is encouraging a sense of realism and an understanding of the ultimate issues in the world of the mind, and here we find little hesitation in accepting the necessity of offensive war. Over a wide range of intellectual life, in both Great Britain and the United States, there is still failure, however, to perceive that the defence of the country of the mind involves, as Mr. MacLeish points out, an affirmation, an assertion of a fighting and positive belief in intellectual things, a willingness not only to resist attacks upon their world and on themselves but also to conceive offensives of their own and fight them through and win them. The city of the mind cannot be defended save from its own ramparts, and this conflict cannot be won by arms alone, for it is a conflict fought for men's convictions and ultimate ideals.

Failure to grasp that essential truth is responsible for much of the weakness and ineffectiveness of our political warfare—for the lack of imagination, to take a recent example, which has failed to grasp the opportunity presented by the Beveridge Report. The War might still be lost, Mr. MacLeish reminds us, whatever the victories of arms, if the battles of belief are lost, above all if the battle to maintain the power and authority of truth and free intelligence were lost, the confidence of men in learning and in reason and in truth broken and replaced by trust in force and ignorance and superstition—if the central battle for the preservation of the ultimate authority of mind in human life ended in defeat.

It is idle to deny that that battle can be lost. Harsh necessity has taught the peoples of occupied Europe, no less than those of the United Nations, that the fantastic plans of the Nazis for the conquest of the mind have to be taken seriously. The havoc they have already wrought in Germany is plainly displayed. One by one the lights of learning and freedom of investigation and utterance have been extinguished in the great centres of Western Europe in spite of centuries of proud leadership and tradition. We know now that the task which confronts the United Nations is not alone that of overthrowing the physical power of Nazi Germany, but also of opening again the frontiers of the mind and destroying the dominion which the prostitution of education by this twentieth century barbarism has imposed first on Germany herself and then on the whole of occupied Europe.

That task of liberation might well cause us to pause in spite of the encouragement which we can draw from the Fighting French and the other free peoples who have escaped to continue the struggle while their country and homes lie still under the conqueror's yoke. It is all the greater task on account of the extent to which the confidence of men in learning and in intellectual things has been undermined even among the free peoples. There was never a time, either in Britain or in the United States, when learning was held cheaper than it is to-day, or when men of learning and of letters had less honour.

Mr. MacLeish has well earned the gratitude of scientific workers, along with that of others who are concerned with the preservation of man's real intellectual and cultural heritage, for his courageous summons to the offensive, and his address has been issued at an opportune moment, when the importance of education in post-war plans not only in Great Britain but also in European reconstruction has received renewed attention. The report, "Axis Oppression of Education", issued by the Inter-Allied Information Committee, gives a picture of the German efforts to suppress every kind of knowledge which is likely to conflict with totalitarian theory, and the brutality as well as systematic thoroughness with which they have set about the standardization of thought; it provides ample evidence of the timeliness of Mr. MacLeish's appeal. In the face of the destruction, perversion or appropriation of educational resources thus portrayed, none can doubt the folly of that purely defensive and detached attitude which too many scientific men and other scholars once adopted of watching the steady deterioration of German science and scholarship under the Nazi system, with not only its contempt for learning but also its restrictions on the wellsprings of the creative thought from which all real progress comes.

This record of the closing of universities, the deliberate destruction of all higher intellectual life, the turning of the universities of Czechoslovakia and Poland, of Athens and Salonika, of Brussels and of Leyden into Nazi institutions for the use of the Germans, the destruction elsewhere of all buildings and the plundering of libraries and scientific laboratories, the persecution, torture and murder of professors and students alike, the determined attempt to deprive the occupied peoples of Europe of intellectual leadership, leaves no room for doubt as to the immense problem which will confront the United Nations in this field of education after the War. Even if we leave on one side the question of education in post-war Germany and the measures to be adopted to revive learning and scholarship in ways that will assist the emergence of a new Germany, the building up of education in the ravaged countries is a task that will demand generous help.

That problem was indeed one of those considered by the British Association Committee on Post-war University Education in its interim report (see NATURE, **150**, 716; 1942). Under the third of its terms of reference, the Committee is charged with surveying the position regarding teaching material, apparatus, books and staff in universities which have been damaged, destroyed, disorganized or closed as a result of war, and to make recommendations for their rehabilitation. The report suggests several ways in which such help could be given, including assistance in the provision of equipment and books, the supply of periodicals issued during the War by scientific and other learned societies in Great Britain, apart from the full restoration by the enemy Powers of stolen or destroyed university property.

Possibly even more important than the material restitution or assistance is that of assisting in the provision of teachers and research workers in the universities of the occupied countries after the War. It may be necessary for British and American universities to train teachers and research workers for some of those universities where staff has been killed or dispersed by the Nazis, and to give foreign students special facilities in the Allied universities. The full benefit of research work in progress in Great Britain, in the U.S.S.R. and in the United States during the War must be made freely available in this task of rehabilitation, and those barriers to the frontiers of knowledge which had been steadily growing in the last thirty years must be finally laid low.

To carry out this task, however, makes large intellectual and moral demands on Allied universities and leadership, quite apart from the call to share physical and material resources. The universities have an important, even a decisive, part to play in reconstruction, and they cannot play their part effectively unless we have clear ideas as to exactly what are their functions in time of war and in the society we wish to build after the War. Without clear ideas as to their place and functions in the educational system, we cannot expect to find them endowed with the personnel or the resources which will enable them worthily to play their part in either national or international reconstruction. That conception lies behind both the first and the second terms of reference of the British Association's Committee. The valuable suggestions made in the Committee's interim report with regard to the modification of the policy and methods of university education so as to promote international collaboration and the free interchange of ideas, and to relate university education to the needs and service of the community, have already been discussed in these columns.

The place of the universities in world education is discussed by Miss H. Wodehouse in *Agenda* of October, 1942. In this thoughtful article, in which the dual aspect of the life of the universities, teaching and research, is carefully considered, Miss Wodehouse suggests that the contribution of the university worker to the conduct of affairs will probably be made primarily on the side of the organization of thought. This influence will be exerted through his lucid and impartial sifting out of the fundamental issues, the clarification of problems as well as the unprejudiced investigation of the facts, through sound judgment and resourcefulness rather than through driving power. This involves, however, that no narrow view must be taken of the functions of the university in the dissemination of knowledge. Such functions cannot be discharged solely through teaching; they must embrace the whole field of adult education and whatever new instruments may be placed in the hand of the skilful expositor by scientific advance.

One acute problem must be frankly faced, because it impinges also on the question of the size and organization of universities, as well as their distribution. Miss Wodehouse, it may be noted, would see possibly some limitation on the numbers of universities themselves, if not of the students attending them, but urges a determined effort to improve the standards and conditions of the university colleges. This effort must of course involve the safeguarding of the independence and freedom of utterance and investigation of their teaching as well as of their research staff. This is fundamental, for the universities cannot make their full contribution to the national life unless they are free to handle controversial subjects according to their best judgment without pressure from sectional or prejudiced interests.

That fundamental liberty must include not merely the right of investigation—which in Great Britain has scarcely been denied—but also the equally important right to teach controversial subjects. Unless that right is acknowledged and is used with wisdom and with force, the universities cannot maintain the vital touch with the whole life of the community essential for them to exercise their full power. No task may make more searching demands on the wisdom and judgment of the members of a university, but it cannot be evaded if we are to have an educated people and an electorate competent to meet the demands of democracy. Nor indeed, as Miss Wodehouse shows, is such teaching of controversial subjects either rare or impossible.

In his survey of reconstruction problems in the House of Commons on December 1, Sir William Jowitt devoted his closing remarks to the question of education. There is, as he said, a wide measure of agreement as to the main lines educational advance should follow: the placing of the full-time schooling of the child on a sound basis; the efficient organization of part-time education and of adult education; the establishment of a finer and more intimate relation between industry and education; and the determination of the appropriate units of education administration.

Some of these problems have been reviewed in a pamphlet, "Education: A Plan for the Future", published on behalf of the Association of Directors and Secretaries for Education by the Oxford University Press, and the administrative problems were reviewed in Mr. H. O. Lester Smith's recent book, "To-Whom do the Schools Belong?". The pamphlet just mentioned enumerates for immediate and detailed investigation, first, the recruitment, training and remuneration of teachers; secondly, the re-definition of the areas and functions of local education authorities; and thirdly, the establishment of the Board of Education as the Government Department responsible for the supervision of all educational work. Taken by itself, the third proposition, with its implications in the field of health, might prove incompatible with that overdue overhaul of the machinery and functions of government on the lines of the Haldane Report, while the suggestion that the local education authority is the proper authority to look after both the health and education of children is, to say the least, open to challenge; but there can be no question as to the importance of the administrative problems involved and of bringing to them a new spirit and an open mind in determining the functions of ministries and the relation of research and professional interests to the administrative machine. Clearly it is desirable that each type of authority should be examined to decide on the fact rs which make for strength and efficiency and those leading to weakness or apathy. Such an examination is an essential preliminary to a constructive re-definition of administrative areas which draws on the accumulated experience of the past to provide for the efficient administration of the educational system of the future.

The importance of such questions may none the less be over-emphasized, and in the chapter on university and adult education the Association of Directors and Secretaries of Education does something less than justice to the place and contribution of the universities, both in reconstruction and in the educational system of to-morrow. True, as is pointed out, there should be closer co-operation between the universities and local education authorities in the discharge of their responsibility to the adult population, and the universities may well come to assume much larger responsibilities in adult education by exploring new ways of furthering that object. If education for citizenship and the ideal of public service is, however, to gain its full place in university life, if the emphasis is to be placed on the responsibilities rather than the opportunities of a university career, it will not be sufficient merely to consider questions of access to the universities rather than those of organization and curricula within the university. The British Association Committee and Miss Wodehouse are here on much firmer ground than the Association of Directors and Secretaries of Education.

We shall not secure the most effective contribution of the universities to the reconstruction of Great Britain or of Europe merely by ensuring that all young men and women who have shown their ability to profit by a university education should have the opportunity of proceeding to the university. With that we must at least ensure that there is some acknowledgment of civic responsibility by those admitted, some attempt to fit themselves not merely for a career but also for service to the community. To defer entry to universities until after a year of approved national or international service, whether civil or military, is a wise if not indispensable corollary to the rendering of access to the universities wider and easier for those possessing the ability to profit by such training.

Even if with this goes the institution of entrance tests of the type suggested by the British Association's Committee in its report, the universities may still fail of their full purpose unless they can solve for themselves the ultimate problem of democracy—the reconciliation of freedom and discipline. Their freedom of investigation and inquiry, both in the field of physical science and in the controversial problems on which the social sciences inevitably impinge, must be guarded as jealously as their freedom of utterance, and their right to guide opinion within or without their walls by unbiased and searching inquiry and fearless and frank statement of fact and inference. That freedom and those rights can only be exercised when they are linked to the self-discipline essential in scientific investigation and in the teaching of difficult controversial and living problems. The success or failure of reconstruction may depend on the extent to which the universities succeed in solving this central problem and most searching test of democracy, and in sending out into the world men and women who have not only learned to reconcile for themselves freedom and discipline, but in doing so have also acquired a spirit of service and a zest for life.

The field of reconstruction in Great Britain and in Europe, and supremely the rehabilitation of academic and professional life in the devastated lands of Europe, provide the universities with an unrivalled opportunity to guide and sustain the generous spirit of youth in paths of service to humanity, and will in time repair the havoc which ten years of barbarism have wrought in European culture and learning. The Government's recent decision regarding the calling-up of university entrants taking arts courses should not be considered apart from these wider claims on the universities for the man-power and woman-power to build the peace when the War is won. It would be a disastrous economy to pursue any policy, even in this crisis of man-power, which disturbed unduly the balance of education and deprived us in the post-war years of exactly that type of ardent, trained and intelligent youthful leadership for which Sir Stafford Cripps has so eloquently appealed.

"VIS ET PRAETEREA NIHIL"—THE PSYCHOLOGY OF A DYNAMIST

My Self, My Thinking, My Thoughts

By K. W. Monsarrat. Pp. ix + 140. (Liverpool: University Press of Liverpool, Ltd.; Bickley: Hodder and Stoughton, Ltd., 1942.) 7*s*. 6*d*. net.

THIS book should be read in conjunction with the author's larger work, "Human Understanding and its World", published in 1937. In the present book, Dr. Monsarrat contends that the methods which have been successfully used in elaborating a consistent picture of the physical universe may be equally successful if applied to an evaluation of thought processes and the individuals engaged on such processes.

Dr. Monsarrat points out that when we apply our minds to the study of what used to be called matter, all inquiries as to what it *is* lead to a dead-end because they are unanswerable—the only answerable inquiries are those which ask what it *does*, how it acts. This leads him to deny the existence of any inert or static reality, and to affirm that all items of reality are "power-items". Since the observed properties of an electron are wholly accounted for by its electrical charge, Dr. Monsarrat, as a positivist, feels entitled to regard the electron as an item of energy and nothing more. Inquiries as to the nature and provenance of this energy are improper and unanswerable; they are unanswerable because the first egress of this energy into the realm of the observable is effected through a quantum emission, and the sequence of states and events leading up to a quantum emission is entirely hidden from us. Even apart from this, it is improper to ask what the electron *is in itself*, since our observation only shows what the electron does in a transaction with some other power-item—a power-item 'transacting' in isolation is unthinkable, and the observation of a power-item in action involves a transaction with the observer.

Consequently, since all knowledge is of items in relation to other items, Dr. Monsarrat abandons the search for absolute truth as chimærical and adopts the relative truth of consistency as his critical canon. For him, true and untrue are "synonymous with congruous and incongruous, accordant and discordant". In other words, "truth" is a property of thought transactions enabling them to be carried forward, and without which thought must either cease entirely or blur out into incoherence. The atom, then, is a dynamic assembly of power-items in action, the molecule is a larger assembly of such atomic assemblies, molecules themselves form higher-order "congregates" which by interaction with other congregates acquire stable structure and pattern, giving individuality, form and properties. All individuals are compounded of power-in-action—this view satisfies the consistency canon, and is the only view which satisfies it.

Turning now to a study of thoughts and the thinker, the author at once encounters a difficulty connected with the possibility of observation. He points out that while we most certainly know, since this is an immediate given, yet because psychic processes go inexorably forward in the time-continuum we can never know our own knowing. Introspection is therefore impossible. Dr. Monsarrat obtains access to the character of his own thinking by making the assumption that his own speech-behaviour gives a reliable account of the thoughts which produced it. This assumption is, of course, a very considerable one, and the author appears to furnish no other warrant for it than to point out that it involves no inconsistency—it enables him to prosecute his inquiry in a coherent manner. Analysis of his own speech-forms convinces Dr. Monsarrat that he too is compounded of power-in-action and nothing more, and that so-called material determinations are merely the relationships limiting this power. Matter is thus dispensed with, the body-mind problem ceases to vex, living and lifeless become names connoting no real differences, the metaphysician is finally deflated, and the man of science is left alone in a monistic universe of which he is the sole interpreter. "Influence is fundamentally of one kind—its effects vary only because it is variously organized."

In his earlier book, Dr. Monsarrat had referred to "the essential δύναμις which is, for us, Nature itself".

How do assemblies and organization come about? The author says, "I envisage the atoms as constructed of complementary power-units bound by their need for each other". This archetypal union gives us the clue to the simple formula at the end of the book by which the world may find issue from the ills which beset it. Dr. Monsarrat sees three ways lying open to the world: the predatory way, which is the way of competition, power-politics and grab; the way of fear, which is the way of religion; and the way of grace, which is the way of science and intelligence. His formula for the way of grace lays down that individuals should "seek their own pleasure by discovering what will please their associates, and by giving them these pleasures".

It scarcely needed the writing of a new book to prove that if everyone *were* unselfish the world would be a happier place. What is really needed is a formula for the steady advance of mankind towards the actual practice of such unselfishness, and such a formula science has not yet produced, and indeed shows little prospect of producing. Surely it is foolish to expect such a formula from those who hold that man is merely a complicated molecular aggregate, and that an adequate account of his nature and dealings may be given by reference to the physical observables which he embodies. Man *is* different, and many of his specific differences are touched upon by Dr. Monsarrat in a way which brings home to the reader the fact that the author has not met with a full measure of success in complying with his own self-imposed critical canon of consistency. He admits that certain individuals (metaphysicians, ore gathers) indulge in processes of abstraction the product of which is "fantastic"; he maintains that common-sense opinions issue from a haphazard survey guided only by desire; he points out that the predatory way and the way of fear have been the ways of choice for the greater part of the individuals in human history so far. There are then, and history shows that there always have been, trends of the whole individual which run counter to other trends of the same whole individual, and a monistic science cannot integrate these two sets of tendencies into a unitary framework, still less can it heal the conflict between them.

It is not clear what exactly the author conceives power-in-action to be, nor whether he understands power-not-in-action to be a possibility. In his earlier work he stated that the properties of an electron are wholly accounted for by its electrical charge, "electrical charge being a term we use to describe a particular sort of behaviour". There are still minds which reel at the thought of behaviour with nothing behaving, of action without an agent, or of patterning without something patterned, and it may be doubted whether this book will dispel their last doubts. The author makes great use of the idea that the concept of power is derived from the fact that the individual's first, primitive and irreducible affirmation is an affirmation of himself as *able and acting*, but he neglects the fact that this is an affirmation, not of unsubjectivated acting, but of the *self's* own action—*I* am acting; *I* am knowing.

With the best will in the world, I was unable to find that the numerous diagrams threw any light on the matter under discussion in the book.

J. Leycester King.

First Steps in Astronomy without a Telescope

By P. F. Burns. Pp. x+214. (London: Ginn and Co., Ltd., n.d.) 5*s*.

THE late Sir Frank Dyson, when speaking on an educational platform, used to express his disapproval of the omission of so fascinating a subject as astronomy from schemes of science instruction in schools. Nor was he satisfied with the reply that the skies are most attractive when children ought to be in their beds asleep, and that anyhow telescopes are not so easily come by as test-tubes. So much is experimental work preferred to observation and calculation that, as the author of this book says, very few children leave our schools with even a fragmentary knowledge of the starry heavens and of the place of the earth in the universe. To those teachers who would like to remedy this defect, Mr. Burns's book will at once appeal. In writing it he has had also in mind young people who are members of the A.T.C. or J.T.C., or who as guides and scouts study for the astronomer's or star-man's badge. The needs of adults also, who wish for guidance in the study of the heavens, have definitely determined both the approach to, and much of the subject-matter of, this introduction to outdoor astronomy. The book is clearly written, carefully graduated, abundantly illustrated, and beautifully produced. It should take its place not only as a text-book, but also as a gift-book.

Control of the Common Fevers

By Twenty-one Contributors, arranged with the help of Dr. Robert Cruickshank by the Editor of *The Lancet*. Pp. vi+361. (London: *The Lancet*, Ltd., 1942.) 12*s*. 6*d*. net.

THIS is a book which will appeal to a large circle of readers, especially health officers and laboratory workers. The subjects discussed are diphtheria, streptococcal infections, scarlet fever, erysipelas, puerperal sepsis, rheumatic fever, pertussis, measles, the common cold, epidemic influenza, the pneumonias, enteric fevers, bacterial food poisoning, bacillary dysentery, gastro-enteritis, undulant fever, cerebrospinal fever, poliomyelitis, catarrhal jaundice, Weil's disease, small-pox and the Rickettsiases. The text is liberally interspersed with charts and diagrams, and a short bibliography of mainly British and American works is appended to all but one (puerperal sepsis) of the chapters, while suggestions for further reading are made at the end of the book.

A Handlist of the Birds of the Sevenoaks or Western District of Kent

By James M. Harrison. Pp. xviii+165+68 plates. (London: H. F. and G. Witherby, Ltd., 1942.) 30*s*. net.

MR. HARRISON'S book is a large and detailed work. The forty-one coloured plates are from good original water-colours by the author, and there are several half-tone and line illustrations.

The observations recorded are those of the author gleaned over a period of twenty years, correlated with those of as many other ornithologists as the author himself could discover. A bibliography, glossary of scientific terms and an index are appended. The work is necessarily specialized and will appeal mainly to those living in the west of Kent and to other British ornithologists.

GOVERNMENT AND SCIENCE IN GREAT BRITAIN*

By The Right Hon. SIR STAFFORD CRIPPS, P.C.

THE problem of the utilization of the scientist in the war effort is one that has been much discussed, though there is in reality no difference in the principles that should be applied in time of war and in time of peace. Whether it is for the purpose of winning victory in war, or of winning decent standards of living in peace, we should equally desire to utilize the highest degree of scientific knowledge in our industries.

There are two main factors in this problem: the provision of an adequate supply of skilled scientific staff, and the proper utilization of the scientific staff available. The neglect of scientific organization, and the failure to appreciate to the full the great part that science was bound to play in a modern war, led us, in the pre-war years, to neglect the organization of the scientific side of war. This we have attempted to remedy in the typical British way by improvising an *ad hoc* organization to deal with the various problems as they arose. We have not created a tidy, blue-print plan of scientific organization of the war effort, but have rather attempted to make the best use of our resources at those points where the resources seemed likely to produce the most valuable results in the quickest time. Hence our structure is one which it is easy to criticize as lacking method and orderliness, but, on the whole, it has, I believe, done as much for us as would any more tidy plan have accomplished, unless such a plan had been laid down and worked out well in advance. In sketching that organization it is perhaps easiest to start at the top.

There are five members of the War Cabinet who are, more or less, directly concerned with scientific matters and who thus represent in the War Cabinet some portion of our scientific effort. In addition to them, the Paymaster-General is a pure scientist and, in a very direct way, is able to assist and advise the Prime Minister who is, of course, Minister of Defence also, upon scientific matters.

In the War Cabinet, the Lord President of the Council is responsible for the Scientific Advisory Committee, which has wide terms of reference upon all scientific matters; and through that Committee the Cabinet is in touch with the Royal Society and with all the principal learned societies of Great Britain. The pooling of scientific knowledge throughout the Commonwealth is assisted by the Committee's association with the scientific liaison offices of the Dominions, and valuable contacts for the exchange of information have also been established with the appropriate bodies in the United States. The Lord President is also responsible for the Engineering Advisory Committee, which carries out similar functions in the field of engineering.

The Council referred to in the Lord President's title is, of course, the Privy Council, and this has long been associated with scientific research. It is the parent body to the Agricultural Research Council and the Medical Research Council, and to the Department of Scientific and Industrial Research, which originated in the War of 1914–18. This latter body is, in its turn, responsible for the National Physical Laboratory and many other research bodies and organizations; and is in intimate association with other research associations both Governmental and industrial. All these are, as it were, centralized research and advisory bodies serving equally any Department.

Next we come to the Minister of Production. Last September three distinguished scientists were attached to the Minister of Production in an advisory capacity as full-time employees of the Government. These advisers are available to assist in all the Departments and can recommend measures for more effective co-ordination. They also act as a link with the British Central Scientific Office in Washington, which co-operates with the members of the supply missions in their joint working with American science. In addition, the Minister of Production is responsible for the Radio Board, which was set up recently to co-ordinate the whole of the work on radio in all the Services, including the Post Office. I preside, in my personal capacity, over this Radio Board on behalf of the Minister of Production.

The Minister of Labour and National Service is responsible for the Central Scientific Register and, in collaboration with the universities, the professional institutions, and the other Government departments concerned, as well as with organizations in Canada and the United States, he has seen to the training and mobilization of our scientific man-power. This has been a most difficult task, especially having in view the enormous growth of scientific personnel required in the Services for operating some of the newest devices.

The Minister of Home Security deals with the specialized scientific needs arising out of the problems of security against air attack, and is responsible for a research and experimental department concerned primarily with protection against the effects of bombing.

The fifth member of the War Cabinet is, of course, the Minister of Defence, and he is connected with the scientific side of the defence services for which the two Secretaries of State and the First Lord of the Admiralty are responsible. He also acts as chairman of the Anti-U-Boat Committee, which deals, among other things, with the scientific side of the anti-U-boat warfare.

So much for the highest level. Next we come to the various supply ministries and the fighting Services. There is a host of liaison committees at different levels between these different Ministries for the exchange of scientific information and experience, but each has its own scientific organization under a director of scientific research. The Ministry of Aircraft Production also has an important organization devoted to radio development, under the controller of communications equipment; though there are, in addition, many scientists operating outside the research sphere, both in development and production, and on operational planning.

One of the most marked developments during the War has been the growth of the application of purely scientific methods to operations, and there are now large scientific staffs in all three Services devoting their skill and energy to operational research.

Co-ordination of Planning and Development

The need for close linkage between the experience in the field and the planning and development of new weapons has been fully realized and methods for obtaining this have been gradually improved as the War has proceeded. Recently a new deputy chief of the Imperial General Staff has been appointed with the responsibility for ensuring that the Army requirements—and the means of fulfilling them—are projected against the background of modern science and research. In addition to being a member of the Army Council, he is a member of the Ministry of Supply Council and of a number of technical committees of that Ministry. He has under him a scientific adviser to the Army Council, who is also a member of the Scientific Advisory Council of the Ministry of Supply.

---

* Address before a conference of the Association of Scientific Workers on "Planning of Science: in War and in Peace", held during January 30–31.

In the same way the chairman of the Aeronautical Research Committee is also a member of the Air Council and of the Ministry of Aircraft Production Supply Council, thereby giving a scientific link between the Air Ministry and the Ministry of Aircraft Production.

On the whole range of specialist committees, dealing with every aspect of the air programme, the Air Ministry, the Admiralty, and the Ministry of Aircraft Production are represented.

In the main testing establishments there is complete co-ordination between Service and civilian staff, who together carry the responsibility for testing. In a similar way the controller of communications in the Air Ministry is also controller of communications equipment in the Ministry of Aircraft Production and sits as a member of the Radio Board; as also does his vice-controller in my Ministry, who is also scientific adviser on telecommunications to the Secretary of State for Air. In this way we have been able to co-ordinate closely the work between the scientist and the Service user.

I have given these indications of the method of organizing scientific work and co-ordination in order to show that at many levels there is a close integration of the work.

This is not to say that, with ample staff and plenty of time, some better organization might not have been elaborated; but it is sufficient, perhaps, to indicate that the Government attaches the very highest importance to the proper utilization of our scientific effort and has gradually built up during the course of the War a machinery which, from the practical utility point of view, has enabled us in many branches of science to keep well ahead of our enemies.

Government and Industry

A great deal of our scientific strength in Great Britain is of course not in the employment of the Government at all but in the employ of private companies. Many of the great pre-War industrial organizations already had highly skilled research laboratories, which they have extended and which are now working whole-time on Government work.

It is not an easy matter to co-ordinate these organizations, as there has been, in some cases, a not unnatural reluctance for industrial research departments to pool the results of their research, though in other cases this pooling has been done most willingly and to the fullest extent. All these research organizations are, in one way or another, linked up with the various Supply Ministries, though we have not yet reached a perfect method of co-ordination and there is still, I believe, room for a better integration of this section of research and development.

There is one additional feature which I should mention, and perhaps I may do this especially in association with my own Ministry. We have an Aeronautical Research Committee with a number of sub-committees, the members of which are drawn from technical Government staffs and independent scientists with the necessary qualifications. From time to time the membership of these bodies is changed with the view of giving a freshness of outlook; but the difficulty is, of course, now being felt that so many scientists are either in Government or industrial employment that it is not easy to find independent scientists to serve.

In addition to this, there are advisory committees from the industries themselves consisting of engineers or scientists to whom specific problems may be referred or from whom advice may be sought upon the way to tackle definite questions.

I think that our main difficulty with regard to the proper utilization of the scientists in this war has been our failure to realize, at a sufficiently early stage, that this was going to be a truly scientific war, and that the battle would not be won merely by the physical ascendancy of our race but rather by the ingenuity of those who have been trained in our secondary schools, technical colleges, and universities. This realization has gradually grown upon the country and we are now fully alive to the fact that our survival and our victory depend to a great extent upon the output of our scientists and our research institutions, and that everything must be done to utilize to the full that very high degree of scientific intelligence which Great Britain undoubtedly possesses.

We need not be too critical of the exact manner in which that scientific knowledge is made available, provided only that it is made available and that there are no difficulties from those who still, perhaps, fail to realize fully how great a part science must play.

The scientists of Great Britain have undoubtedly achieved the most remarkable progress during the years of the War, but we must do everything in our power to maintain the lead that we have gained; I know that, as in the past our scientists have without stint given their services and their devotion to the country so, too, in the future we can look to them for new implements and new devices which will make our salvation certain and will hasten our victory.

THE PLANNING OF SCIENCE

AN open conference on the "Planning of Science" was held in the Caxton Hall, London, on January 30 and 31, under the auspices of the Association of Scientific Workers. Perhaps the most significant comment on the subject was unspoken. For the first time those wishing to confer on the planning of science presented a substantial problem in London traffic control; 30 per cent of those wishing to attend the first session were—despite resort to a remarkably uncomfortable scale of overcrowding—unable to hear the discussion even from the lobbies; overflow accommodation, regrettably unavailable for the first session, had to be made available for the third; the least well-attended session was still a large gathering. No better index of the radical change in public interest need be sought.

Sir Robert Watson Watt, president of the Association of Scientific Workers, at the conclusion of his opening remarks, read a message of greeting dated from Moscow, January 29, 1943, from Vladimir Komarov, president of the Academy of Sciences of the U.S.S.R., and Nikolai Derzhavin, chairman of the Soviet Scientists' Anti-Fascist Committee and member of the Academy of Sciences of the U.S.S.R., in the following terms :

"The role of science is a particularly big one in this War. It was with great satisfaction that we learned that British scientists are devoting their Conference to questions leading to the solution of problems connected with the rapid rout of Hitlerism.

"Since the War broke out Soviet scientists have devoted all their energy to the war effort. Under war conditions, all Soviet scientists have turned their efforts in one direction—to help the Red Army and the industry of the U.S.S.R. This has meant the complete reorganization of all scientific research work. It was necessary to select a few of the many problems on which the Academy of Sciences of the U.S.S.R. was working, those few which gave an answer to war-time problems.

"The Institutes of the Academy of Sciences selected, from among the subjects being worked on, those which are of importance to the War. The programme which was drawn up in this way was communicated to military organizations, who confirmed the importance of the subjects mentioned, and added new problems interesting the Army and Navy. After this, we held a number of conferences with leading commanders of the various arms of the Fighting Services and with leaders of the defence industries. The result was that we were able to concentrate the efforts of our scientists on the most important tasks and also to make full use of our numerous institutes and laboratories.

"The results of 1942 show that we have given great help to the Red Army and have been able to provide the front with many new weapons.

"The reorganization of the work of the Academy of Sciences of the U.S.S.R. in order to satisfy the needs of the Army, made a number of organizational measures necessary. In the early days of the War, the Academy of Sciences organized a Commission for the Mobilization of the Resources of the Urals, Western Siberia and Kazakhstan for Defence Needs. This Commission is working under the guidance of the president of the Academy of Sciences of the U.S.S.R., Vladimir Komarov. The significance of the work done by the Commission may be judged by the fact that the workers of the Commission received Stalin Prizes in 1942.

"Three other Commissions are working for the purpose of mobilizing scientists for defence : first, the Naval Technical Commission, consisting of representatives of the Academy of Sciences, naval establishments and scientific research institutes outside the system of the Academy ; second, a War Medicine Commission ; third, the Commission for the Mobilization of the Resources of the Volga and Kama Districts for Defence Needs. In addition to the work of strengthening the might of the Red Army, scientists of the Soviet Union are continuing their theoretical investigations.

"Without analysing the measures proposed by you for organization of the work of scientists in your country, measures which are dictated by the specific features of the country concerned, we express our confidence that our colleagues in science will take all necessary measures to hasten the rout of the Hitlerite gangs and bring nearer the complete victory of the United Nations."

The Conference then listened (by the courtesy of the B.B.C.) to a recorded exchange of greetings by trans-Atlantic telephone, between Dr. Harry Grundfest, of the Rockefeller Institute for Medical Research and national secretary of the American Association of Scientific Workers, and Sir Robert Watson Watt.

The Central Direction

Sir Stafford Cripps (whose address on "Government and Science" is reproduced in full on p. 152 of this issue) outlined the somewhat complex structure of ministerial, departmental and extra-departmental groups concerned with governmental control of science in application to the war effort in Britain. A schematic diagram was included in the exhibition of photographs, diagrams and printed matter which formed part of the Conference. While the diagram is known to contain errors of balance and detail, it is a useful preliminary attempt to bring the present British arrangements into a single picture.

Sir Alfred Egerton presented a corresponding outline of the arrangements in the United States of America.

Dr. David Shoenberg, who has worked under Kapitza in the Institute for Physical Problems of the Academy of Sciences of the U.S.S.R., Moscow, spoke on "Wartime Science in the U.S.S.R.". He supplemented his account of the structure for central direction of the scientific effort in U.S.S.R. by reading the organizational portions of the greetings from Moscow reproduced above. The general organization outlined by Dr. Shoenberg was also represented diagrammatically.

Existing Systems

It was not unnatural that the detail of the pictures seen across an ocean or half a continent should appear simpler than that of the close-up. But over-simplification in presentation of the less familiar systems of the United States and the U.S.S.R. could not wholly account for the criticisms of that of Great Britain. The Conference may not have judged the organizations catalogued by Sir Stafford Cripps as harshly as did the speaker who quoted Lord Chesterfield's opinion, according to the Duke of Wellington, of the generals of his day : "I only hope that when the enemy reads the list of their names he trembles as I do". There was, however, found no one to go beyond Sir Stafford's qualified enthusiasm : "on the whole . . . done as much for us as would any more tidy plan . . . unless . . . worked out well in advance".

Speakers who had first-hand knowledge of conditions in the United States and the U.S.S.R. emphasized the large scale of provision for research, for scientific and technical education, and for the application of science by both these allied nations. The general lavishness of their support for science, the magnificent facilities, the numerical adequacy of the research teams and the scale of technical help and workshop services were all contrasted with the limited provision at home. "Boston Tech." and "Cal. Tech." are the giants of their class, but the somewhat smaller institutes in the U.S.S.R. are no less generously appointed.

Dr. Shoenberg gave an impressive account of the way in which scientific work was from the beginning linked to purpose, and of the "conscious planning" which distributed inter-related problems over a number of institutes, with consequent avoidance of overlapping, and facilitation of collaboration. He emphasized the scale on which long-term biological research is being maintained in the U.S.S.R. and contrasted this policy with the British policy of diverting biologists towards filling gaps left by our inadequate supply of physicists.

The speed with which the gap between research and production could be bridged in the United States was illustrated by the case of a pilot plant for a new explosive-manufacturing process. This plant was in production within thirty days of the conference between the university chemist and the chemical engineers. Sir Alfred Egerton, who gave this example, selected "the high scientific importance of the Industrial Research laboratories" as the greatest difference between the United States and Great Britain.

The Ages of Wisdom

The most insistent criticism of the existing arrangements in Great Britain was directed against the general failure to bring the young scientific and technical workers in the laboratory or the plant into the formation of policy, the implicit assumption that the most distinguished men are the oldest men, the septuagenarian, octogenarian and (in one case) nonagenarian chairmen, the obstacles preventing the minor member of the scientific democracy bringing his views to the governing body.

It was recognized that the young worker should not be snatched from his productive work to full-time service in governing or co-ordinating bodies, but it was regarded as impossible for the most modern scientific technique to be represented by the once brilliant laboratory or plant worker who has been so long in 'management' that he is no longer in touch with the thoughts and ways of his immediate successors.

The Conference was reminded of C. K. Mees's dictum that "the man on the job knows most, the Director of Research very little, the committee of Vice-Presidents nothing at all".

There was constant emphasis on the need for planning and co-ordination from below, to complement and consolidate with planning and co-ordination from above.

Closely related to this group of comments was that which called for direct contacts between the relatively junior executive officers in the Fighting Services and the junior scientific workers who could solve the problems posed by their serving contemporaries.

A Central Scientific and Technical Board

Mr. E. D. Swann, speaking for the executive of the Association of Scientific Workers, reviewed the deficiency in the applications of science to the war effort which the Association discussed in its earlier Conference, and the partial rectification which has been achieved in the intervening year. These deficiencies include failure to pool information and facilities, to concentrate effort on vital war needs only, to ensure full co-ordination between Government departments and between these departments and industry, to utilize fully the initiative of the individual worker.

Towards the fuller rectification of these defects the Association proposes the setting up of a Central Scientific and Technical Board, composed of scientifically and technically qualified persons. This Board would be in direct contact with the War Cabinet and able to raise items on its agenda. In this important respect the proposed Board would differ from the existing advisory bodies. Its functions would be to advise the War Cabinet on scientific matters and to relate the country's scientific effort to the strategy determined by the War Cabinet. In relation to science the Board would possess executive powers enabling it to survey scientific problems, to allocate priorities to the various problems and the necessary resources to deal with them. It would establish the date by which scientific projects should reach completion and review their progress and the resources allocated to them from time to time. The Board would need the authority to initiate or stop programmes of work and to transfer personnel where necessary. It would also need powers to demand any scientific or technical data from any firm or industrial department.

It was clearly recognized that over-planning of science may produce a greater measure of frustration than does our present scale of under-planning. What is sought is a system which will make it easy for the individual scientific and technical worker to give his full effort, with adequate facilities, in that grouping which is best adjusted to the need of the moment, and with an understanding of the broad reasons for its programme in relation to that need.

"We do not want the individual worker to spend a large part of his time explaining to central planning boards what he would have been doing if he had not been explaining to them. We do want the central boards to help the workers to do their work better, by explaining to them why they are asked to do certain things in a certain grouping at a certain time. But mainly we want to ensure that the things and the grouping and the timing are part of one integrated plan of utilization."

Science and the Soldier

Air Chief Marshal Sir Philip Joubert said "the association of science and the fighting man is no new thing. But perhaps it has reached its highest development during the adolescence of the Royal Air Force". He described the "harmonious co-operation of science and the military art which achieved outstanding success in the Battle of Britain".

Sir Philip's main theme was the growth, the essential nature, and the necessary limits of operational research.

"The desirable situation is when the Service side realizes a series of needs and passes straightforward questions to the scientist. Such questions must, of course, be capable of consideration by scientific methods. By this I mean they must be questions of fact, not of theory. The facts of the war in the air can be clearly stated. For example, it may be necessary to decide how many flying hours with so many aircraft are required to achieve a certain result. Given past experience, scientific analysis will quickly provide the answer to this question. Naturally, all the questions are not so simple in form.

"The position becomes more complicated when the military staff are not quite certain what they want and are unable to state their case clearly. The scientist then must grope for his solution and it is here that a very serious difficulty may arise.

"The prosecution of war is, in principle, an art. The methods to be employed are based on past experience and study, but their application to a particular problem must be a matter of judgment. The military man, by education and experience, if he is to succeed, must have this judgment. The scientist is not fitted, either by his training or his experience, to exercise that judgment. But if he is insufficiently guided by the military staff, in the course of his researches he is almost certain to trespass into the realm of military art. It is therefore of the utmost importance that the military staff should give the scientist the clearest guidance on his duties.

"If, however, the scientist never initiates any action and always waits to be asked a question by the military staff, he will lose half his value. It is a truism to say that the solution to a problem which puzzles those who are constantly working on it is often grasped very quickly by a new-comer, and it is certain that the advent of the Operational Research Sections has resulted in many difficulties being cleared away by the sound advice they have given. I must, however, insist upon the point that this advice should be confined to the purely factual aspect of any problem. To my mind it is not the business of Operational Research Sections to advise on future operations. They can examine past operations and draw conclusions from them, but it is for the military staffs to apply these conclusions as modified by their military judgment."

The natural extension of the methods of operational research into post-war life generally was treated by a member of an operational research staff in a thoughtful and stimulating contribution, one of several from which the importance of operational research methods emerged very clearly.

Science and the Educational System

It was noteworthy that the first and the last addresses to the Conference, as well as many between, ascribed the major obstacles to full utilization of science in the service of humanity to the unbalance in education between science and the 'humanities'. This diminishing but persisting unbalance, it was stated, accounts for the famine of scientific and technical workers which now faces us. It accounts, too, for the disproportionate effort required to convey to the administrators, the politicians and the industrialists the true nature of science in the service of civilization, its method and its possibilities.

It is, however, impossible to await the radical cure, which requires first the re-education of our educators. The process must be undertaken, but we must simultaneously take measures which will have earlier effect.

Science and Parliament

The Parliamentary and Scientific Committee owes to the Association of Scientific Workers alike its foundation and its resuscitation from the remarkable suspension of its activities which was decided on at the beginning of the War. The Committee goes far towards solution of the problem of acquainting Parliament with scientific opinion on all matters of current importance. It aids the presentation of questions and resolutions in Parliament, and approach to Ministers by deputation and interview.

Lord Hinchingbrooke offered advice to the Conference on the technique of bringing scientific ideas into the forum of Parliament. He said that politicians are people who know a little about a very great deal, and urged the need for showing clearly the application of any idea presented, and for avoiding dilution of important information by its inclusion in bulky and frequent collections of miscellaneous matter.

Prof. S. Chapman, while refusing to accept politics as anything higher than a regrettable necessity in the relations of science and the community, is convinced that scientific workers should be of and among the legislators, should be in the Mother of Parliaments as of right and of duty. Science should be recognized as one of the Estates of the Realm, and should have its life representatives in the Upper House. These "bishops of science", men and women, should be chosen by the scientific workers themselves, and should come from the age groups of the thirties and forties as well as from the fifties and sixties. They should number twenty rather than two, they would not necessarily be the very best scientists, but should have knowledge of politics and affairs in addition to their scientific knowledge.

Science and Industrial Managements

Colonel W. C. Devereux, managing director of High Duty Alloys, Ltd., spoke as a "professional manager", from that inarticulate class called "management".

"I hope I am right in believing that the day is past for ever when the scientific worker in industry—the works chemist or metallurgist—was regarded by the management as a necessary evil; as someone who should be put away quietly in a dirty little shack miscalled a laboratory, and brought out only to put on the carpet and abused for anything that had gone wrong, or to produce an immediate solution to any troubles which would not yield to more direct methods of attack. To-day, the value of scientific research and control is appreciated by progressive management as an essential part of a manufacturing organization. I do not believe that good management, and by this I mean competent men who understand the technical processes they control, finds any great difficulty in interpreting and applying the recommendations of the scientific workers. The greater difficulty is to convey to the scientist the problems requiring solution and to direct him along the right lines of investigation."

Kettering, of General Motors, sums up the position very wisely when he says: "It may not always be the best policy to adopt a course that is best technically, but those responsible for policy can never form a right judgment without knowledge of what is right technically".

After outlining the organization of the scientific and technical staff in his own companies—on a scale exceptional in industry—Col. Devereux quoted the results of two investigations initiated by his economy committee, one for fuel economy in which the £35,000 capital expenditure incurred in providing re-designed combustion chambers and the like was saved within the first year of use, and one for modifications in a bought-out material, the cost of the investigation being repaid by the savings on a single day's purchases.

Col. Devereux was critical alike of the research associations and of the existing national laboratories. The former "have not so far been a really important factor in industrial development. This is readily understandable when one considers the . . . lack of backing which these organizations receive from industry and the Government." "Our existing national laboratories . . . sometimes become a sort of blissful oasis where certain scientific gentlemen can browse in quiet seclusion to their hearts' content." His constructive prescriptions for a better state of things deserves more space than can be given in this summary of nine hours of wide-ranging discussion; he proved himself a powerful and stimulating friend of the scientific worker.

Joint Production Committees

A substantial proportion of the detailed discussion on the immediate fuller application of scientific and technical knowledge to war production was devoted to the problem of Joint Production and Advisory Committees in industry. The Association noted with special satisfaction the acceptance by the Minister of

Aircraft Production of its contention that scientific and technical staffs should have their own representation alongside 'management' and 'labour' in these committees. The strength of the resentment felt by the Conference in relation to "the deliberate policy of the Employers' National Federation to exclude from the Joint Production and Advisory Committees any representatives of the staff" was unmistakable.

A representative from Hayes made a valuable contribution describing the success of local co-operation between scientific and technical staff and other organized groups of the labour force towards mitigating the evils resulting from this exclusion from Joint Production Committees. Only one speaker was able to present himself as an actual member of such a Committee, although another was able to underline the absurdity of a situation in which one technical worker, excluded from membership of a Joint Production Committee, has already been co-opted to the Committee on four separate occasions to help in the consideration of special problems.

International Co-operation

Throughout the discussion there was constant reference to the need for closer inter-Allied co-operation, and in particular to the need for wide extension of the existing arrangements by which young workers from the war laboratories visit their colleagues in other countries, not merely for discussion but also for work side by side in Allied teams. It was emphasized by Sir Robert Watson Watt that only the indispensables should be spared from this vital work.

The inadequacy of the initial response by the United States and Great Britain alike to the U.S.S.R. offer of help on the synthetic rubber problem was cited as an example of grievous failure in inter-Allied co-operation, not yet incapable of rectification. Immediate action, again by way of a personal mission of young and active workers, was called for.

Determining the Future

The contributions by Sir Lawrence Bragg, "The Position of Scientists after the War", by Prof. P. M. S. Blackett on "The Rehabilitation of Fundamental Research", and by Prof. H. Levy on "The Basis of Scientific Planning", introduced the discussion, in the third and final session of the Conference, on "Determining the Future". The proceedings at this long and crowded session were of such importance that they merit separate treatment. No attempt is, therefore, made to summarize them in the present review.

Summary

The points on which the most vigorous criticism, and pressure for reform, were expressed in the Conference were:

(1) The need for a stronger, simpler and more closely knit fabric of central direction of scientific effort in the War, controlled by active scientific workers with full knowledge of War Cabinet policy and current strategy.

(2) The need for constant participation by the young scientific worker in the shaping and direction of policy and in its execution.

(3) The need for direct interchange of view between the junior user and the junior scientific worker. (This was admirably summed up by Mr. Hilton Brown in a broadcast to schools on February 2, in which he showed the junior military officer and the junior scientific officer at the foot of the two legs of the letter A, without adequate provision of bridges below the apex.)

PLACE OF RESEARCH IN THE CONTROL OF INJURIOUS INSECTS*

By Prof. J. W. MUNRO

Imperial College of Science and Technology

It is well to remember that it is not necessary nor is it even practicable wholly to exterminate populations of injurious insects. For example, the Ministry of Agriculture has found that the growing of wheat on land carrying a population of wireworms of 600,000 per acre is economic, but on land carrying a higher population it is risky. It follows that if on heavily infested land the wireworm population could be reduced below 600,000 per acre the growing of wheat would be economical and for practical purposes control would be achieved.

As an example of the different kinds of work or investigation which the control of injurious insects entails I propose to take the control of insects affecting food-stuffs and other produce during transit and storage. These insects are, especially in wartime, a potential danger to the national economy, and methods of controlling them are only now being developed in Great Britain.

In 1929 I was asked by the Australian Dried Fruits Board to advise and assist them in dealing with infestation of sultanas and raisins by the phycitid moth *Plodia interpunctella*. The infestation occurred in these dried fruits on their arrival in London, and persisted and increased during storage in the warehouses prior to marketing.

The facts concerning this infestation and the measures which had then been taken to combat it were these. Infestation undoubtedly occurred in the drying and packing sheds of the fruit growers in Australia. It occurred in the packages of the fruit on shipment, and on the voyage from Australia to England became aggravated during the passage through the tropics. Measures were being taken in Australia to reduce infestation and, in Great Britain, a system of fumigation of all incoming fruit had been introduced. Cases of fruit arriving on shipboard in the Thames were transferred to barges for delivery to various warehouses up river, and all these cases were fumigated. A further step towards control was taken at that time by centralizing storage in a single group of warehouses instead of spreading it over many warehouses, and it seemed as if the prospect of control was promising. In 1929, however, it became evident that these measures were unavailing and it was then that I accepted responsibility for a review of the whole question of control to be practised in Great Britain and for the conduct of such investigations as might be necessary to ensure it.

A rapid survey of the conditions then prevailing showed that failure to achieve control was caused by the inefficiency of the fumigation of the fruit in barges and chambers, and it became necessary to investigate this. It soon became evident that fumigation practice was wholly empirical and that that could only be remedied by investigation of a number of problems. The more important of these concerned methods of determining the concentration of the gas obtained during the fumigation both in the air space of the barge or chamber and on and within the sultanas and raisins. Then came the need to study how a gas behaved during fumigation, to study the factors that affected its distribution and determined how much of the gas was adsorbed on the walls of the barge or chamber, on the fruit boxes and on the fruit itself, and how much was available after adsorption had taken place to perform the primary function of killing the insects. Then came other problems. It became necessary to ascertain for a number of fumigants what concentrations were required to kill the insects—caterpillars, chrysalides and moths in various stages of development and in different physiological states. For this experimental work it was necessary to rear large numbers of insects, and before much progress had been made with that, quite a number of problems of entomological interest arose, such as why some insects became sterile when reared at temperatures above 27° C. and why on some foods some species flourished better than others.

---

* Substance of a discourse before the Royal Institution on December 18.

Already a wide field of investigation had become necessary involving work in physical chemistry and insect biology. Almost at the beginning of the physical chemical work on the behaviour of gases during fumigation, it became clear that mixtures of gases used as fumigants had obvious disadvantages. Such mixtures are used when the more toxic or active gas is inflammable or explosive and the purpose of the mixture is to reduce the risk of fire and explosion by using a non-inflammable gas as a blanketing agent. It soon became apparent that the failure of the fumigation system used by the Australian Dried Fruits Board lay in the use of a mixed fumigant. This fumigant was a mixture of carbon disulphide and carbon tetrachloride. Carbon disulphide is reasonably toxic, but inflammable and explosive. Carbon tetrachloride is poorly toxic to insects and non-inflammable.

The operator in charge of fumigation was, in fact, in a dilemma. If he made for safety against fire risk he was almost certain to fail to get a high percentage 'kill' of the insects. If he made for a high 'kill' he ran serious risk of fire and explosion. The practical result was that he had to risk survival of some insects because after one or two accidents he dared not risk more explosions. In doing this he allowed a population of insects to build itself up in the warehouses in which the fruit was stored after fumigation. We were not aware of that at the time. Meanwhile, we decided as a result of preliminary chemical work to recommend the abandonment of a mixed fumigant and the adoption of the simple fumigant ethylene oxide. After some experimental work in barges we secured a complete destruction of insects by using ethylene oxide, and the prospect of controlling Plodia in dried fruits looked good.

It was not until ethylene oxide had been in use for some time that we found that, even when we were certain all insects in the fruit had been destroyed, complaints were still made by merchants that the fruit they purchased was infested. Then we had to try to find out the defect in our new methods. There was no defect in our system of fumigation of fruit on arrival. The cause of continued complaints was that fruit was becoming re-infested during storage in the warehouse and this was a direct result of the failure of the mixed fumigant previously used. Here we were faced with a new practical problem. We had controlled insects in fruit during the transfer from shipboard to the wharf by fumigation in barges. We now had to control them in the warehouses. A series of rather costly experiments carried out showed that fumigation of large warehouses of 150,000 cubic feet capacity was at that time impracticable. Leakage was considerable and cost almost prohibitive. I then decided to try the use of a spray to kill caterpillars crawling on the fruit boxes and around walls and dunnage. That was not very promising. Then with some hesitation I decided on a rather bold experiment. A research student in my department was studying the rhythm of emergence of moths from their chrysalides. These moths showed a marked rhythm of emergence, leaving their chrysalides when the temperature of the day fell about dusk. It seemed possible that if the moths in the warehouse also showed such regularity we might be able to destroy them by spraying. The spraying of caterpillars on wares and walls failed because only those caterpillars which were exposed could be killed by the spray then in use, while large numbers hidden in cracks and crevices could not be reached. On the other hand, if by a systematic attack on the moths as they emerged from these cracks and crevices we could in time reduce their numbers below an economic level, control would be achieved. By sending up into the warehouse at dusk a fine spray of pyrethrum in oil we found we could kill large numbers of moths, and then the boldness of our strategy was rewarded by a wholly unexpected result. The mist sent up settled everywhere, forming a fine film of pyrethrum in oil, and this film proved fatal to caterpillars crawling over it. It was in fact so effective that in the following season we abandoned spraying at dusk and instituted a regular system of spraying in the daytime.

During three seasons in London and two seasons of this work in Bristol, Liverpool, Manchester and Glasgow we continued this combination of fumigation in barges and spraying in warehouses, and found then that we had successfully controlled infestation by Plodia.

Over the period 1930–35 the cost of laboratory research, experimental work at the docks, and actual control work at the docks was in round figures £30,000. In 1939 the saving effected as a result of the control measures devised had reached a value of £150,000. One further feature of this work deserves mention. Throughout the whole period of the work, both in the early stages when the work was experimental and in the later stages when it became routine practice, there was the fullest confidence and co-operation between the research workers and the officers of the Australian Dried Fruits Board.

In the course of our laboratory investigations we were acquiring knowledge of the behaviour of fumigants and of the principles underlying fumigation; we were also acquiring much knowledge of the habits and biology of insects. The work done on fumigants may readily be divided into large-scale experimental work at the London docks and laboratory experimental work. The first concerned the application of fumigants to ships and warehouses and dealt with such problems as the measurement of gas concentrations during fumigation; the distribution of the gases ethylene oxide and hydrogen cyanide in empty warehouses, the effects of different methods of stacking or piling goods on the distribution of these gases in barges and warehouses, and the various means by which distribution could be improved by using vaporizers and fans.

The laboratory work dealt with the determination of fumigants. First, methods of determination were devised, and then the amounts of gas remaining in various food products were determined. This work was of high importance because it afforded the means for ascertaining how far various fumigants could be used with safety on various foods under varying conditions, what residues were left in the foods and what measures were required to reduce these residues to the lowest level. The results of all this work have recently been summarized and published by the Department of Scientific and Industrial Research as a pamphlet, under the title "The Principles and Practice of Fumigation".

The biological work done may also be divided into field work carried out at the London docks and laboratory work. The field work comprised studies of the life-histories and habits of various insects living in warehouses, and studies of the effect of sprays and fumigants on the populations of these insects. Laboratory work dealt with the factors affecting insect fertility both during development and in the adult stages. Systematic revision of groups or genera of the most important insects infesting foodstuffs was undertaken, notably a revision of the moths of the genera Ephestia and Plodia. Other subjects studied were the resistance of insects to high temperature, the experimental analysis of the factors governing the hours of emergence of insects from their pupæ, the nutritional requirements of important species, and certain aspects of respiration. Then came various studies of the toxicity of fumigants, ethylene oxide, hydrogen cyanide and sulphur dioxide, and of various contact insecticides such as pyrethrum and the thiocyanates.

In 1937 a small beetle belonging to the family Ptinidæ, or spider beetles, appeared in the fruit warehouses and caused considerable concern. The chief cause of this was that, unlike *Plodia interpunctella*, this beetle was not very susceptible to our Pyrethrum insecticide. This new problem, together with others which had arisen both in our chemical and in our biological work, clearly showed the need to extend our scientific work to include insect physiology, and the most cogent argument for that lay in the part knowledge of physiology could play in giving us a better understanding of our insecticide problems. So, with the assistance of the Agricultural Research Council, we embarked on physiological work, and because the insecticides (fumigants and sprays) with which we were concerned had to act through the skin or cuticle of the insect, it seemed reasonable to begin with a study of the insect cuticle and its bearing on the mode of action of insecticides. The work undertaken was broadly considered under three main heads: a study of the changes occurring in the cuticle during growth of the insect, a study of the biochemistry of the cuticle, and a study of the lesions produced in various organs or tissues when the insecticide had penetrated the cuticle.

Meanwhile our practical work on the control of insects infesting dried fruits had ceased and I was concerned with another practical problem, the control of the bed-bug. That work was being undertaken on behalf of the Medical Research Council, and in the course of it a fraction of heavy naphtha as produced in gas works was examined as a potential insecticide. This heavy naphtha comprised a number of constituents: indene, pseudocumene, coumarone and paraffins. Of these it was thought pseudocumene would be the most insecticidal, and in particular it was taken for granted that the paraffins were inactive and were in fact unwanted diluents. On this assumption it was decided to eliminate the paraffins, but when this was done the toxicity or insecticidal value of the heavy naphtha fell markedly and some of the paraffins had to be restored. After some further work the practical use of heavy naphtha against the bed-bug was made possible and the work on it ceased. Meanwhile, the interesting scientific problem of the part played by the apparently inert and relatively non-toxic paraffins remained, and by means of a grant from the Department of Scientific and Industrial Research the problem was studied further by investigating the permeability of the insect cuticle, again as an aid to the understanding of the mode of action of insecticides. This investigation had not gone far when it became evident that the really fundamental questions to be answered lay in the realm of surface physics and colloid chemistry, and again the scope of our scientific work was extended.

With that broad but unavoidably confused sketch of the relationship between the practical problem of controlling injurious insects and the laboratory investigations which are essential to its solution, I think we can now consider the place of research in entomological practice. The following items of experience gained in this work deserve notice because they illustrate three fundamental principles in applied entomology. First, that the way to tackle a practical problem is to get right down to it. When that is done the scientific problem becomes clearer. Second, that the research necessary for the solution of practical problems can only be defined when both research and practice keep in the closest touch with one another. In so young a science as biology applied in fields other than medicine it is idle to suppose that research basic to agriculture or to industry or to public health can be planned within the four walls of a laboratory. Third, that the scientific work required for the solution of practical problems cannot be confined by any doctrinaire or academic definition of the branch or branches of science in which it lies. The fact that a practitioner is a zoologist or an entomologist by training is no excuse for his failing to follow his work into chemistry or physics if that is necessary.

I should like to stress these points because recent experience in dealing with war-time problems has itself stressed them. The practical work on fumigation and on the use of pyrethrum-in-oil films carried out in controlling insects infesting dried fruits forms the basis of the extensive control of insects affecting foodstuffs now practised by the Infestation Control Branch of the Ministry of Food. All the fields of research opened up in attaining the control of the moth *Plodia interpunctella* are now being worked in and extended by the recently established Pest Infestation Laboratory of the Department of Scientific and Industrial Research, and it is, I think, significant that the most recent development of all, the investigation of the factors affecting the passage of insecticides through the insect cuticle, offers reasonable promise that it may before very long provide a means of greatly saving insecticide materials. These are now, as a result of the war, 'in short supply' and urgently needed not only for the protection of growing crops and of food in store but even more for the control of flies, mosquitoes and other insect vectors of disease which are so important a factor on all the fronts on which we are now fighting.

Experience in the last three years has stressed another important feature of insect control work. In spite of the great extension of practice and of the greatly increased tempo of research and particularly of what is called short-term or *ad hoc* research, it is the long-term or basic research which is paying the highest dividends in practical results. This may seem paradoxical. The objectives of short-term or *ad hoc* research are those thought to be within reasonably easy reach, and the research itself usually covers a severely restricted field. The objectives of basic or long-term research are usually distant and the research itself is nearly always planned on a broad basis. It is precisely this planning on a broad basis that makes it valuable not only in science but also in practice, and in the light of the experience of the last three years I am almost tempted to believe that if provision is made for long-range research on a broad basis in which the closest contact is maintained with practice, much of the *ad hoc* work carried out in relation to the control of injurious insects might be dispensed with. That may, however, be to simplify matters too much, because there is often a gap between basic research and practice which can only be filled by *ad hoc* work. On the other hand, my own experience strongly suggests that it might be better if this necessary *ad hoc* work were carried out jointly by the practitioners and the research workers.

In recent years in applied entomology there has grown up a kind of investigation commonly called *ad hoc* research which has in my opinion little value. It is the kind of work which assumes that any kind of investigation, because it relates to an injurious insect or to the use of insecticides, is *ipso facto* of economic or applied scientific value. The literature of economic entomology is overburdened with accounts of work of that kind almost to the despair of the serious research worker and of the practitioner alike, because the work described is too often neither good science nor good practice. The possibility that in economic as in scientific work the discovery of new laws and principles may solve a problem cannot be overlooked, and in seeking to discover new laws and principles relating to insect behaviour or to the mode of action of insecticides it may be the simpler, if not the only, approach to study quite other insects than the injurious ones and then, having gained an understanding of principles, apply these principles to the solution of the practical problem.

I refer to this misunderstanding of research in applied entomology because recent experience has thrown it into high relief, and because the same experience has emphasized the value of a background of research as free and untrammelled by immediately practical considerations as is possible in a workaday world.

I favour, then, the freest basic research in the closest contact with practice, but I often meet with the view that free research aimed at the discovery of new laws and principles is incompatible with practice; that it is impracticable in war-time; that research and practice cannot run in double harness, and that their aims are totally different. That their aims may be different I do not for a moment deny, but that they are incompatible is demonstrably untrue.

So it comes about that in this field of work in the control of injurious insects there is and must be a continuous going to and fro between practice and research and between research and practice. They are not incompatible; they are complementary, and it may be some compensation for the sorrow and tragedy of war if in this and in other fields fundamental research and practice can continue to work together.

MUSEUMS AND EDUCATION

By G. F. WESTCOTT

Science Museum, South Kensington, London

THE present world upheaval is partly due to the fact that man's control over his physical environment has advanced rapidly, while the ideas and methods which he uses for controlling his relations with his fellows have developed much more slowly.

One of the most important psychological features of man is his emotional and habit-forming nature. This nature has been essential to the development of civilization, by enabling the individuals of a nation to act together as a community with a common purpose. It is particularly valuable when reasoning cannot be used, whether for lack of intelligence or time or when the amount of evidence available to all is insufficient to produce logically a reasonable uniformity of opinion. No human being can be logical all the time: we all use many ideas, obtained by habit or suggestion or by previous reasoning, which are frequently emotionally reinforced and have become practically impervious to reason or suggestion in normal conditions. These ideas are often the guiding principles of our lives, which enable us to act quickly and help to give us our characters. They simplify our lives and save us from becoming choked by logical entanglements. It is an example of the small part reason plays in human life that these most fundamental ideas, particularly liable to emotional reinforcement, have received the least amount of study by scientific methods.

In the past, poor communications and the strong influence of tradition have been safeguards against the sudden rise over a large area of a new system of ideas. But to-day there is a loss of faith in tradition and, as we have seen only too clearly, the tremendous developments in our methods of communication and propaganda, especially when combined with repression and the destruction of all opposition (which can also now be organized and applied rapidly over a wide area), can change the purpose of a nation in a very short time, with disastrous results to the whole world. Emotions are so strong that they can be acted upon to reinforce almost any idea, whether right or wrong, and even against the balance of direct evidence. Repeated propaganda, especially if contradictions are suppressed, can also be used to form mental habits and so strengthen particular ideas.

In the past there has been a number of ideologies, sometimes on a national basis, and competition between them may have tended to ensure the survival of the fittest, even though this may often have meant mainly the ability to destroy its rivals by force or subterfuge; but the world seems to be approaching a time when, at least in certain directions, there may be only a few generally accepted views. It is essential, if development is not to be retarded, to provide for constant criticism and research, so that the best ideas may have a chance of coming into use. Perhaps a practical objective science of ideas and thought will be developed as a safeguard—indeed, work has already been done on these lines. This would result in further mental instruments being devised to enable man to transcend his natural abilities.

A practical ideology must satisfy at least two conditions: it must be expressed in such a way that it will communicate at least some acceptable meaning to many of the individuals concerned, and it must be sufficiently in touch with reality on essential points to be workable. Many of the most important ideas on which our present civilization has been built, especially in the moral and political spheres, are upheld by the authority of tradition. This, owing to its strong power of resisting change, has probably provided the stability needed for the development of civilization in other directions. Tradition, however, in these spheres seems to be losing its power and also appears to be too resistant to change to keep pace with modern events, leading to the danger and actual occurrence of revolutions based on the authority of dominating individuals using all the modern methods of mass influence. It would be disastrous if civilization were to be left to the control of such ephemeral and fortuitous authorities, and it seems clear that there is an urgent need for some new kind of authority, more universal and stable and capable of rapid adaptation to new factors in the situation as they occur. The position is perhaps similar to that of several centuries ago, when the authority of tradition began to give way to the authority of knowledge based on experiment in the domain of the physical sciences. The rapid advances which have been made in science are mainly due to the use of methods which largely eliminate the effects of emotion, habit and prejudice; if we are to advance quickly and safely in the moral sphere, I believe we must use similar methods.

At the present time it may still be expedient that our conduct and ethical ideas should be guided largely by tradition, to prevent confusion and rash experiments, but I think that with an adequate historical background there would be little danger of trouble occurring even if people should be encouraged to think logically for themselves on such subjects. In the absence of emotional reinforcement the position would be similar to that in science, where a new idea, even if truer than previous ideas, meets with great opposition until it has been thoroughly tried out and assimilated into the main body of accepted theory.

The evidence on moral and political subjects obtained and presented by scientific methods is steadily increasing and may soon be sufficient to ensure a reasonable uniformity of educated opinion, if made readily available to all adults. Particularly since the beginning of the present century, new ideas and methods have been introduced into psychology and, though as yet psychology is apt to be regarded more as an art than a science and there is much conflict of ideas still to be resolved, our knowledge of human conduct has been considerably increased. The time is not far distant when our knowledge of how men do act will greatly influence our views as to how they should act. Such an ethic would increase our understanding and sympathy for others, whether nations, races or individuals.

It seems essential, especially if democracy is to survive and produce the best results, that as many people as possible should be taught how to think for themselves, and how to protect themselves from emotional exploitation for false or evil purposes. The individual must become more critical; though fortunately he cannot escape his emotional nature, and thus deprive life of much of its interest and drive, he can do his best to ensure that his feelings shall only be used to reinforce ideas, and particularly innovations, which conform with the best evidence available.

I would suggest that, among the objects of education in a democracy, the following are important:

(1) To provide the individual with a reasonably stable and dependable background for his mental development.

(2) To teach him how to think for himself and how to obtain reliable data, and to encourage him to use reasonable criticism and constant research.

(3) To help him to learn how to use his emotions and how to guard himself against their misuse by others.

(4) To discover and develop his abilities, so that he may become a useful member of the community.

Museums as an Educational Medium

In this particular connexion let us consider our national museums. The four selected objects are of the kind for which museums could be of the greatest assistance, and the following indicate some of the ways in which museums could help to attain these objects.

(1) For the later mental development of the individual a historical background is the most universal and stable. A knowledge of the past is a great help in understanding and dealing with the present and preparing for the future. Museums, by preserving the physical evidences of the past and by orderly arrangement, can do much to provide a common historical background.

(2) By examining examples of the work of men of the past, of the triumphs of critical thinkers and of scientific research, the visitor to a museum is bound to be impressed by the value of these methods and may be encouraged to try to use them himself. Museums and their associated public libraries would themselves be one of the sources of reliable data.

(3) Museums at the present time only help towards obtaining emotional control indirectly; for example, by inference from the insight they give into historical processes. To be more effective (*a*) there should be a museum (or part of a museum) devoted to psychology, and (*b*) an attempt should be made in museums generally to illustrate the influence of widespread (and consequently often emotionally reinforced) ideas on the development of civilization, so as to show which have produced permanent and which relatively fleeting effects. The evidential material thus made available in an interesting way would provide a stable background for judging the value of ideas.

The opportunity afforded by museums for studying the actual evidence on which authorities have based their theories, and the illustrations of the methods used to develop our understanding of the universe should help to produce a more rational attitude towards authority in general. Though we cannot be expert on all subjects, we can carefully examine the evidence in some small selected part of the field of knowledge and so obtain a better understanding of the foundations on which authority rests, particularly in the domains of science and history.

(4) By covering the whole field of man's thought, knowledge and activities, museums could help to discover to the individual (and his teacher) any particular interests or abilities which he may possess, and so enable him to decide in what way he could best serve the community and himself—that is to say, stimulate education rather than inject instruction.

Advantages of National Museums

Museums, especially the national museums, have advantages from an educational point of view over local teaching establishments in some respects. For example, they contain unique examples of historical and evidential value; their material can be made to appeal to nearly all the human senses, and thus be made more interesting; expenses can be incurred for special exhibits which would be beyond the means of every local school or college; they can cover nearly the whole field of human knowledge and endeavour. As the educational possibilities of museums become more generally recognized, the time may come when visits to them will be included in the experience of all individuals (perhaps specially arranged tours to cover several weeks). The organization and display of museums would be adapted to increase their educational value.

One can visualize the time when the national museums will be organized to cover all the branches of knowledge systematically. For example, there would be a museum or museums illustrating what may roughly be defined as "Man's methods of dealing with himself and with his fellow men": this might include such subjects as government, laws, customs, warfare, religions, philosophies, education, psychology, physiology, anatomy and medicine.

These museums would deal with their particular subjects fairly fully and contain as much as possible of the important actual evidence available, such as historical relics. Descriptive labels would be attached to each exhibit: these should include sources of evidence and appropriate cross-references, and thus encourage the visitor to further research and self-education. Exhibits representing recent advances in our knowledge in the present or of the past would be brought particularly to the visitor's notice; in fact, it would be to museums that the public would naturally go for the latest information on such subjects.

Special Museums

In addition to these national museums dealing with limited and specialized subjects, I think there is another type of museum which would be of great educational value. This would deal with the development of civilization in general and as a whole, and form an introduction to, and a link between, the national museums. It would be integrative, and in it an attempt would be made to make the past live again. The ideas, politics, social organization, arts, crafts, and sciences, etc., of the past would be combined. It would be impossible to show the complete story of the development of civilization in the world as a continuous process, and so only certain important phases would be selected for treatment. For example, for a museum in Great Britain, a selection of periods such as the following might be made: early Egyptian; early Greek; Roman; Europe in Dark Ages; Italian Renaissance; and then, say, three periods of English history. The final period would be outside the museum—the actual present world. Of course, the periods, if thought desirable, could be extended backward in time to prehistoric eras.

In this museum actual relics of the periods would not normally be shown (unless large numbers in good condition happened to be available), but the reconstructions would be made as accurately as possible on the available evidence. Great care would be taken to provide suitable explanatory labels. Such a museum would not claim to represent final truth, but merely to be a careful attempt to reconstruct the past. It would invite criticism and would, of course, be modified as new evidence came to light. Possibly, in suitable cases, the staff might be dressed in the costumes of the periods illustrated, and other means of adding realism adopted.

Mental instruments and methods have developed as well as material instruments, and it is most important to bring this out. Lecture theatres, cinemas and stages, where plays illustrating the life and ideas and demonstrations of the arts and crafts and instruments of the past could be given, might form an important part of the museum. There might also be rooms devoted to the great philosophers, and their philosophies, which influenced the periods concerned.

OBITUARIES

Dr. Cyril Crossland

By the death of Dr. Cyril Crossland on January 7 at Copenhagen at the age of sixty-four, zoology has lost one of its last explorer-naturalists of the Darwin type. He was educated in the Lake District, where his father was a well-known lake painter. During his whole life he suffered from deafness, but this did not prevent him from becoming a personality in Clare College, Cambridge, where he compelled its steward to provide vegetarian meals for him and his numerous disciples.

Wanting an assistant for his researches on the naked Mollusca, Sir Charles Eliot, Consul General and Commissioner, took Crossland to East Africa, where he developed a taste for small boat sailing, which enabled him to explore the coasts of Zanzibar, Pemba and the adjacent mainland. He compared the barrier reefs off the latter with those described by Darwin off Brazil, both series being formed by erosion. Zanzibar proved to be an enlarged portion of the continental barrier, whereas Pemba was an independent elevation; the coastal flats of the whole area were due to a recent lowering of sea-level. No reefs were found that could be considered as due to growth *in situ*. For comparison, he next visited the Azores, having been appointed fellow of the University of St. Andrews, discovering well-consolidated Dendrophyllia, Vermetus and Lithothamnion coastal formations.

In 1904, Crossland proceeded to the Red Sea on a year's biological exploration, in which he covered about five hundred miles of its western coast, collecting all the time. "Its shores are all composed of elevated coral and are fringed with its luxuriant growth, while Barrier and other reefs and patches fill the sea for miles from either shore." The Sudan was being opened up by the development of Port Sudan, and Crossland was given a commission for the economic culture of shell oysters, being allowed a free hand. He ran a farm for the next fifteen years at Donganab, about sixty miles north of Port Sudan, off which there was a maze of surface reefs and submerged banks with clear water between. Here he built a patriarchal settlement for his fishermen and he became a source of supply for Red Sea animals to nearly every school of zoology and museum in Europe. In 1913 he published his "Desert and Water Gardens of the Red Sea", descriptive of the lives of his people and reefs and of the sides of his fault line, more than 1,500 miles linearly of coral reef. In the War of 1914–18 his settlement was useful in policing the Red Sea, and his oyster farm was producing a crop of millions, for he had succeeded, where all his predecessors had failed, in breeding his oysters, laying their spat and protecting their shells. Meantime, the market for pearl shell had gone, Vienna, its chief user, being almost a city of the dead, and he himself driven to hawking his shells where he could. Donganab was abandoned and Crossland came back to England.

During the next twenty years, Crossland used Cambridge as his home base, writing many papers on his collections, those on the chætopods in a class by themselves. There came next that curious expedition on the sailing yacht *St. George*, which anyone could join, each "going as he pleased". He wrote admirable accounts of the calm and muddy seas off Panama and of the fresh volcanic slopes of the Galapagos. In the older bays of the Marquesas corals tried to build in a singularly barren region. He left the ship at Tahiti, where he settled on its coasts for a year, to study its highly developed reefs and a luxuriant fauna, the most easterly outlier of Malaya. The surrounds of Tahiti, Mocrea and later Rarotonga were compared to those of other regions, with striking results. Basaltic stones were found lying in the reef surfaces or bedded in the rock below. The reefs are going back rather than extending seawards, and in extreme cases appear as submerged banks. The lagoons were formed by the hollowing out of an originally continuous reef. These important conclusions were followed by a close study of the corals, on which he was still engaged up to the time of his death.

Crossland, however, was called from retirement once again to go to the Red Sea, being commissioned by the Egyptian Government to found a biological station at Ghardaqa, off the mouth of the Gulf of Suez. Like everything else, he did this well, the facilities for keeping living organisms being excellent. He explored the deep waters of the Gulf of Akaba and of the Red Sea off the same. To-day his station is a flourishing institution and Dr. Gohar, its director, generously extends its hospitality to Western workers.

In many respects Crossland was a most attractive person. He enthused everyone with whom he came into contact, this extending to his native labour wherever he was. His published researches number about forty and are characterized by their original, often unorthodox, outlook. They demand the study of all who are concerned with biological and faunistic research in the tropics. His deafness was a tragedy, for it prevented that personal contact with his fellows so valuable to research workers. J. S. GARDINER.

Dr. Alexander Russell, F.R.S.

DR. ALEXANDER RUSSELL, advisory principal and governor of Faraday House College, died at his home at Mill Hill on January 14.

Dr. Russell was born at Ayr in 1861 and graduated at the University of Glasgow with first-class honours in mathematics and natural science. In 1882 he went to Caius College, Cambridge, and became a wrangler in 1886. He was for a time mathematical lecturer at Caius, and afterwards mathematical master at Cheltenham College and then at the Oxford Military College.

In 1890 Dr. Russell joined the staff of Faraday House, so that he was associated with it practically from the beginning. He became principal in 1909 and remained in this position until 1939, when he became advisory principal, leaving the more active work to a younger man. It was during these thirty years that he built up the college and its reputation, so that the name of Faraday House is always linked with his and can never be dissociated as long as it exists. No successor can take his place.

Many honours came to Dr. Russell during that time. He was awarded the D.Sc. by his old University of Glasgow in 1908 and in 1924 the LL.D. He was elected president of the Institution of Electrical Engineers in 1925 and had been president of the Physical Society and vice-president of the Institute of Physics, and nominated an electrical inspector by the Electricity Commissioners. He was elected to the Royal Society in 1924 and finally in 1940 he was awarded the Faraday Medal of the Institution of Electrical Engineers. There have been only eighteen recipients of this medal since its foundation, and among them are such famous names as Sir Oliver Lodge, Lord Rutherford, and Sir William Bragg.

Dr. Russell had been a pupil of Lord Kelvin, who had been a friend of Faraday, so that an authentic link was preserved, through him, with the pioneer of practical electricity.

Dr. Russell was fortunate in being known in the electrical world in the early days of the practical application of alternating currents and was able to apply his mathematical knowledge to the problems that they raised. His two books, "Alternating Currents" and "Theory of Cables", became standards, and the method he invented for computing the mean horizontal candle-power of a lamp is still called the "Russell angles". He was a most industrious writer and produced a life of Lord Kelvin as well as many papers communicated to the Royal Society, the Physical Society and the Institution of Electrical Engineers. For many years he was a frequent contributor to NATURE.

One of Dr. Russell's great interests was lightning and atmospheric electricity, but during his latter years he became absorbed in the theory of numbers.

In the early days of television, Dr. Russell took a party of engineers to Baird's early studio in St. Martin's Lane. It was suggested that an attempt should be made to transmit a human face, and Dr. Russell was selected for the experiment. It has, therefore, been claimed that he was the first man to be televized, but complete confirmation of this fact is lacking.

Many hundreds of old students of Faraday House College, now scattered all over the world and in the Services, will remember Dr. Russell by his kindness and helpfulness to all who came to him. This is the truest and most lasting memorial to the memory of a great man. W. R. C. COODE-ADAMS.

Prof. R. G. Collingwood, F.B.A.

PROF. ROBIN GEORGE COLLINGWOOD, archæologist, historian, and philosopher, originally acquired his artistic and scholarly tastes from his father, W. G. Collingwood, the friend and biographer of Ruskin, and his Jewish mother. He early became an omnivorous reader and an adept linguist, and thus laid the foundations of the almost universal learning which was the surprise and delight of his friends in conversation. In boyhood, too, he learnt how to use his hands in playing the piano and violin, in draughtsmanship, and in sailing a boat (always a favourite recreation), and he thus acquired the manual dexterity which was later a prominent characteristic, evidenced, for example, in toys he made for his children and in his beautiful handwriting.

At Oxford he came under the influence of Haverfield, who deepened the interest in Roman Britain which he had already caught from his father. But philosophy claimed him, and it was a philosophical fellowship to which he was elected at Pembroke College in 1912. Always too absorbed in his studies to have much time for social distractions, he had comparatively few close friends, although his attachment to those he had, like theirs to him, was deep and lasting. No less enduring was the regard of his pupils, for on them he lavished the resources of his vigorous and original mind, placing philosophical problems in their historical context and illuminating them with his extraordinary power of graphic exposition.

During his years at Pembroke he was working equally strenuously at excavating Roman sites, collecting inscriptions, and re-interpreting the history of Roman Britain. His work in these fields was recorded in a long series of publications, culminating in "The Archæology of Roman Britain" and, finally in the first volume of the "Oxford History of England", on which his fame as an historian securely rests. It was as much for his historical as for his philosophical work that he was elected a fellow of the British Academy and given the honorary degree of LL.D. at St. Andrews.

In philosophy his aim was to persuade philosophers that history was as important for their investigations as physical science. In this aim his work is meeting with some success, although his own philosophy has not yet been so widely accepted as his history. His standing as a philosopher will probably rest ultimately on his "Essay on Philosophical Method"; his later books, "The Principles of Art", "An Essay on Metaphysics", and "The New Leviathan", all contain original thinking of the highest order, and they are written with a lucidity and verve uncommon in philosophical works, but they lack the finish of the earlier book, and over parts of them there hangs the shadow of his increasing ill-health.

Insomnia and overwork had begun to undermine his strength even before he became Waynflete professor of metaphysical philosophy at Oxford in 1935; and the hope that his new office, by easing his teaching burden, might enable him to recuperate and to expound his own philosophy *in extenso* was only partially fulfilled. After a serious breakdown in 1938 he fought a steadily losing battle; in 1941, when he could no longer both lecture and write, he chose to resign his chair. But there was no recovery, and he died on January 9 at the comparatively early age of fifty-three, mourned by his friends as a lovable personality, by scholars in general as one whose contributions to learning have substance and permanent worth.

T. M. KNOX.

WE regret to announce the following deaths:

Sir Robert Armstrong-Jones, C.B.E., consulting physician in psychological medicine at St. Bartholomew's Hospital, formerly general secretary and later president of the Medico-Psychological Association, on January 30, aged eighty-five.

Prof. C. C. Farr, F.R.S., emeritus professor of physics in Canterbury College, Christchurch, New Zealand, aged seventy-six.

Dr. F. S. Sinnatt, C.B., M.B.E., F.R.S., director of fuel research, Department of Scientific and Industrial Research, on January 27, aged sixty-two.

NEWS and VIEWS

Geological Society Awards

THE Council of the Geological Society has made the following awards: Wollaston Medal to Prof. A. E. Fersman in recognition of his fundamental contributions in the field of geochemistry and his researches on the economic mineralogy of Russia; Murchison Medal to Prof. A. Brammall for his notable contributions to geochemistry and petrogenesis, especially of the rocks of Dartmoor and Malvern; Lyell Medal to Mr. D. N. Wadia, lately of the Geological Survey of India, for his work on the syntaxis of the Himalaya and his contributions to the geology of India, especially Kashmir; Bigsby Medal to Dr. G. M. Lees, chief geologist of the Anglo-Iranian Oil Company, for his geological studies on Persia, Oman and his important share in the discovery of oil in England; Wollaston Fund to Miss Ethel D. Currie in recognition of her valuable researches in palæontology; Murchison Fund to Mr. A. G. Davis for his work on the Cretaceous and Tertiary fossils of south-eastern England; one moiety of the Lyell Fund to Mr. F. A. Bannister and another moiety to Dr. M. H. Hey, for their joint X-ray and chemical investigation of minerals.

Highway Engineering at the University of the Witwatersrand

DR. BERNARD H. KNIGHT, research officer in highway engineering in the University of the Witwatersrand, Johannesburg, has been appointed to the newly created chair of highway engineering in that University, with effect from April 1 next. It is believed that this chair of highway engineering, which is tenable in the Department of Civil Engineering, is the first of its kind to be founded in the British Empire outside Great Britain. Its establishment has been made possible by the joint support of the South African Iron and Steel Corporation and the National Road Board. Dr. Knight, who was formerly lecturer in road engineering at the College of Estate Management, London, was appointed senior research assistant in highway engineering at the University of the Witwatersrand early in 1939. Since then, three postgraduate scholarships in highway engineering have been established in its Department of Civil Engineering. The marked development in highway engineering research which has taken place at this University has been made possible by the provision of the new Civil Engineering Laboratories situated in the Hillman Building, which was officially opened by the Prime Minister of the Union of South Africa, General Smuts, in June, 1941.

Science Students and Industrial Experience

THE War is undoubtedly speeding up many changes in our educational habits. Until quite recently, it was the custom for students of engineering only, either during vacation or otherwise, to spend some part of their time in the practice of engineering on the industrial side. The needs of total war have brought out something that has always been latent in every branch of science, namely, its close linkage at some point with industrial practice, either on the side of production or of technological research. It is not surprising, therefore, that students in pure and in applied science, in addition to those in engineering proper, should seek the opportunity of adding to their experience by taking part in industrial life when the opportunity presents itself. This is underlined in the recent report, for the year ending October, 1942, on the vacation apprenticeship scheme in operation at the Imperial College of Science and Technology. The scheme is sponsored by the Imperial College Union, and is under the chairmanship of Prof. H. Levy, representing the governing body.

During the past year, 340 students have spent on the average nearly six weeks in research departments and in works, assisting with special investigations, studying the productive processes and the schemes of organization. Some 170 of the foremost firms of Great Britain and many Government departments have willingly co-operated with the Committee in this venture, and have been sufficiently interested to write reports on progress. The scheme has been extended to cover intending students in the summer vacation prior to entry, provided they have reached the Intermediate B.Sc. standard. Last year 32 students entered the scheme at this stage. Apart from the financial return to the students themselves, it is clear that this will give them experience that must react very favourably on their capacity to assimilate the more theoretical studies with which they are necessarily concerned at college; and the fact that the proportion of students of chemistry, physics and mathematics availing themselves of the opportunity presented is steadily increasing is an indication that the scheme meets a real need. Its educational consequences will be well worth watching.

Government Grant to Universities

Sir Kingsley Wood, Chancellor of the Exchequer, has announced, in the form of a written reply to a question by Sir E. Graham-Little, the Government's policy with regard to financial support of the universities of Great Britain. He said that, although the impact of the War on university finance has so far been less severe than was expected, the Government has maintained unchanged the annual provision for university grants at £2,149,000. This policy was adopted in view of the vital part played by the universities in the life of the country, their essential contributions towards the national effort in war-time, and the prospect that immediately after the War they will be faced with very large demands on their funds in order to resume normal activities. These considerations have lost none of their force, and the Government, after considering a report from the University Grants Committee, has again decided to maintain the provision at its existing level.

Swedish Forest Products

According to the Swedish International Press Bureau, a survey of Sweden's production of forest products of a chemical nature was recently given by Mr. Otto Cyren, director of the Swedish Chemical Office. Speaking of chemical pulp, one of Sweden's most outstanding export products in normal times, he said that Sweden is in a very good position in respect of quality, as the slowly growing timber in northerly regions gives very long fibres, and consequently the strongest pulp and paper are obtained from it. The most important by-product of the sulphite pulp production is sulphite spirit, which up to most recent years was the only product recovered. Mixed with petrol, it was of importance as a motor fuel. The purity of the rectified spirit now surpasses that obtained from grain and potatoes, and it is therefore used also for human consumption. Researches on the possibility of using sulphite spirit as the basis of more highly developed products were not initiated until the present crisis made the matter urgent. As an instance he described the work carried on by the Mo and Domsjo Company. In 1941 this company completed a factory for the production of sulphite spirit with a capacity for 10 million litres of 95 per cent spirit a year. At this factory intensive research work is going on, with the view of producing various synthetic products from the spirit. From the black lye obtained in the sulphite pulp process there are produced *inter alia* certain crude acids, the first factory for using this raw product having been built at the Bergvik och Ala pulp mill. The sebacic acid produced here, called 'pine fatty acid', is used to replace fat in washing mediums, as a substitute for linseed oil in paints, etc.

The output of charcoal in Sweden has trebled in the last couple of years, mainly due to the extensive producer-gas traction of motor-cars, and the by-products from the carbonization are now being recovered more carefully than before. The charring of old tree stumps, with their high content of rosin, alone gives about 20,000 tons of tar a year. Wood tar is now used as motor fuel for fishing boats in place of crude oil, and has probably saved the Swedish high-sea fisheries from total stoppage. It is also used for the production of lubricants. In summing up the situation for the Swedish forest products industry, Mr. Cyren stated that in 1941 the Swedish exports of woodstuffs had declined by about one third, and the pulp and paper by two thirds, compared with the pre-war level. But in compensation the forests, by supplying cattle feed, wood fuel, motor fuel, lubricants, textile material, fatty oils, and a good many other useful products, have saved the country from catastrophe.

Variation in δ Ursæ Majoris

Mr. F. M. Holborn suspected at the end of August that this star was fainter than usual, and this suspicion has since been confirmed by Mr. N. F. Knight, who observed it in North Africa. His latest estimate of its magnitude on December 10 was 3·8–3·9, and on January 14 and 15 Mr. Holborn found that its magnitude was 3·7 (normal mag. 3·4).

Announcements

The following appointments in the Colonial Service have recently been made: H. B. N. Hynes, entomologist, Kenya; G. R. Groves (horticulturist, Bermuda), curator of the Botanical Gardens, British Guiana.

Dr. G. M. B. Dobson's discourse at the Royal Institution on February 12 on "The Air we breathe in Town and Country" will deal with the results of the survey by the Department of Scientific and Industrial Research of the air pollution of Leicester. This was the first detailed survey of the kind ever undertaken in Great Britain. The scientific officer in charge at Leicester was Dr. A. R. Meetham, who was responsible for carrying out the work there.

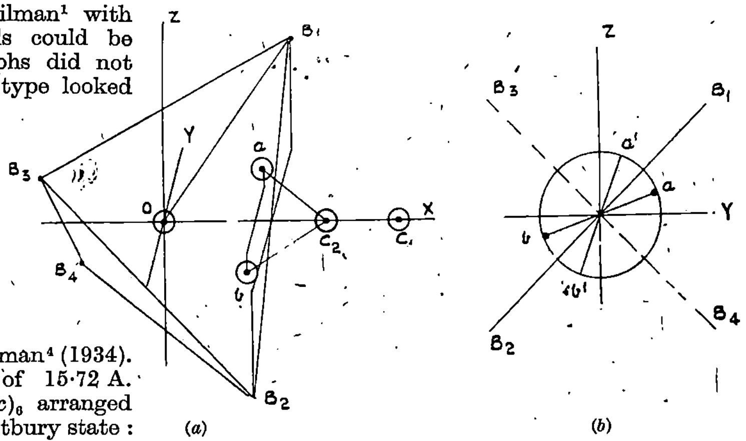
A Change of Symmetry with Temperature

During the course of an investigation into the effect of temperature on X-ray reflexion in crystals, some photographs were taken of basic beryllium acetate to see whether any of the diffuse reflexions observed by Charlesby, Finch and Wilman[1] with electron diffraction in organic crystals could be detected with X-rays. The photographs did not show with certainty any effect of the type looked for, but another effect was observed. At the time (1939), we did not think the matter of very great importance, but recently the results were shown here to Prof. W. T. Astbury, who suggested that they were of sufficient interest to deserve recording.

The structure of basic beryllium acetate has been described by Bragg and Morgan[2] (1923), by Morgan and Astbury[3] (1926) and by Pauling and Sherman[4] (1934). The crystal is cubic and the unit, of 15·72 A. edge, contains eight molecules OBe$_4$(*Ac*)$_6$ arranged in a 'diamond' structure. Morgan and Astbury state: "The unique oxygen atom lies at the centre of a regular tehrahedron of beryllium atoms, while the six equivalent acetate groups are associated with the edges of the tetrahedron. Each acetate group is symmetrical about a dyad axis, that is, its two oxygen atoms are equivalent and the three-fold symmetry of the (CH$_3$) group is for some reason non-effective. The plane of each acetate group, since full tetrahedral symmetry does not extend beyond the tetrahedron of beryllium atoms, must lie oblique to the tetrahedron edge with which it is associated." The positions of the oxygen atoms have been determined by Pauling and Sherman.

The obliquity of the plane of the acetate atoms to the edge of the tetrahedron of beryllium atoms is inferred from a lack of symmetry in Laue photographs taken with the X-ray beam parallel to a [111] direction. As may be seen in Fig. 1 (left) the pattern is not symmetrical about the lines *AA'*, *BB'*, *CC'*, having only simple threefold symmetry when examined at room temperature. However, if the temperature is raised to 100° C. the picture, Fig. 1 (right) becomes symmetrical about the lines *AA'*, *BB'*, *CC'*, and resembles the Laue photograph to be expected from a crystal with holohedral symmetry. The change to this holohedral type of pattern takes place between 30° and 50° C.



(*a*) (*b*)

Fig. 2.

Fig. 1 (right). A few of the weaker Laue spots disappear as the temperature rises, but apart from this (and the intensity changes which produce symmetry) the pattern does not alter in any radical way, so that the change is not to be ascribed to a change of phase. It is reversible, and a single crystal suffers no damage by being repeatedly heated to 100° C. and cooled to room temperature, a fact which also indicates that no recrystallization has occurred. Fig. 1 (left) is not identical with the Laue photograph reproduced in Morgan and Astbury's paper, presumably on account of different conditions of excitation of the X-ray tube. Our photographs were obtained with radiation from a silver target operated at 60 kV. Fluorazure intensifying screens were used; exposure 10 min. at 18 ma.; 5 cm. film to specimen. It will be noted that in Fig. 1 the intense reflections 612, 210, 520 are not accompanied by their counterparts 621, 201 and 502 on the opposite side of *AA'*: in general, the intensity of (*hkl*) is not equal to that of (*hlk*) below 30° C.

The cause of the change in symmetry of the Laue photographs is probably most easily seen by the aid of the diagram (Fig. 2*a*), which is a sketch (not to scale) of part of the molecule near the corner of the unit cube. The unique oxygen atom at *O* falls in

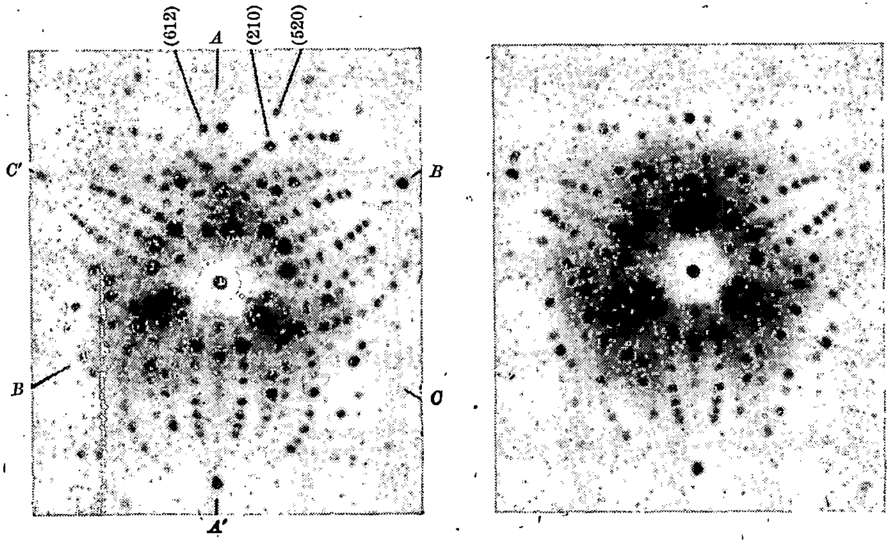


Fig. 1. Laue photographs of basic beryllium acetate. X-rays parallel to [111], [211] vertical. Silver target; Fluorazure intensifying; 5 cm. film to specimen. Reduced in the ratio 3:2. Left: at room temperature. Right: at 100° C.

the centre of the regular tetrahedron B_1, B_2, B_3, B_4 of beryllium atoms. The acetate group  $CH_3—C\begin{smallmatrix}\diagup O\\ \diagdown O—\end{smallmatrix}$ is a plane Y-shaped structure, a methyl group at its foot, a carbon atom at its middle and two structurally equivalent oxygen atoms at the extremities of the arms. These are shown in the sketch at C_1, C_2, a and b. In the 'end on' view of Fig. 2*b*, B_1B_2, B_3B_4 are the traces of the edges of the tetrahedron of beryllium atoms viewed along XO. These edges are parallel to 110 axes of the unit cube and lie in planes of symmetry for the holohedral crystal. The line ab joining the two oxygen atoms is, at room temperatures, inclined to the line B_1B_2 (and B_3B_4); as the temperature rises, its mean position must be such as to produce a symmetrical distribution about this line. This can occur in several ways; for example: (1) if the atomic vibrations carry ab to $a'b'$ (symmetry about B_3B_4 is secured automatically if it is present about B_1B_2), (2) if the acetate Y rotates about its stem so that ab in Fig. 2*b* describe a circle. The mean position of these two atoms must have a symmetrical aspect to produce the photograph of Fig. 1, and must therefore be in, or at right angles to, B_1B_2.

Further investigation might throw light on the amplitude of the thermal movements to which the observed change of symmetry is due: the onset of vibration across the symmetry plane should be accompanied by an abnormal rise of specific heat. Molecular rotation in nitrate crystals has been reported by Hendricks, Posnjak and Kracek[5] and is accompanied by a change of symmetry such as that here recorded. It seems that if Laue photographs are used to determine symmetry, they should be taken at as low a temperature as possible.

We are indebted to Dr. D. V. N. Hardy, Chemical Research Laboratory, for the preparation of the single crystals of basic beryllium acetate used in this investigation.

The work described above has been carried out as part of the research programme of the National Physical Laboratory, and this paper is published by permission of the Director of the Laboratory.

Magnetization of Matter by Ultra-Violet Radiation

Ehrenhaft and Banet have reported[1] finding that nagnetic poles are produced in various pieces of 'non-magnetic" and annealed pieces of iron by exposure to ultra-violet radiation. The detecting instrunent used was a simple compass needle. Focken[2], on the other hand, repeated these experiments with nore sensitive apparatus, but found no evidence of any such induced magnetization. We have recently attempted similar experiments.

The deflexion magnetometer used was of the reflecting type and its sensitivity was 9,800 mm. at one metre per oersted, as compared with 9,000 mm. at one metre for the instrument used by Focken. We consider that for specimens distant 10 cm. from the needle, a change in the magnetic moment of 0·25 C.G.S. unit could be detected with certainty. The ultra-violet source was a D.C. mercury arc enclosed in a quartz envelope. The specimen under test was placed with its centre 10 cm. from the needle and in the end-on position with respect to it. In this position, one surface of the specimen was fully exposed to radiation propagated at right angles to its length. Each specimen was also exposed to radiation propagated, approximately parallel to its length, and to do this conveniently, each was moved to the broadside position. In these positions, the material was always placed at right angles to the magnetic meridian. With the arc running, and the specimen in place, but shielded from the radiation by a shutter, the magnetometer reading was noted. The shutter was then opened, the light spot from the magnetometer being kept under observation. This procedure ensures that the only change in conditions is exposure to radiation, other magnetizing influences such as the fields of the arc and the earth remaining substantially constant throughout any given test.

The experiments were also repeated for end-on and broadside positions when the radiation was concentrated on the specimen by means of a quartz lens.

Three types of materials in the form of rods, approximately 8 cm. long, were tried, namely, transformer iron, mild steel and a hard steel.

In no case could any change be detected in the magnetic condition of the rods, either at the instant of exposure or after exposures ranging from ½ hour to 3 hours. By placing the rods in a vertical position and illuminating as before, we tested for possible magnetization at right angles to the length. Here, also, the results were negative.

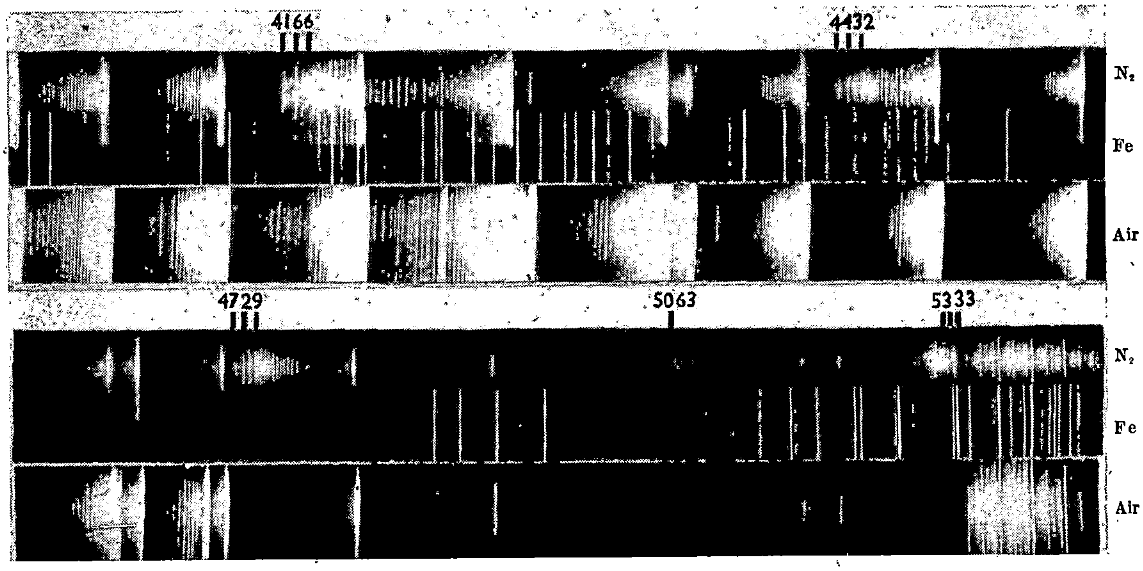
A New Band Spectrum Associated with Nitrogen

DURING an attempt to improve measurements on the Vegard-Kaplan bands of N_2 using a silent (ozonizer type) discharge through nitrogen as source, as recommended by Wulf and Melvin[1], three new bands in the blue region of the spectrum were observed. These bands were afterwards obtained quite readily in an ordinary induction-coil discharge through nitrogen at relatively very high pressure (around 10 cm. mercury). The bands were obtained with commercial nitrogen, with special oxygen-free nitrogen, and with atmospheric nitrogen made by bubbling air through alkaline pyrogallol. The bands do not appear at lower pressure or in discharges through air. The bands disappear if a little oxygen is mixed with the nitrogen, and hydrogen and water vapour also have an inhibiting action. In all the spectra taken, the NO γ and OH bands were weakly present, but all the experimental evidence seems to favour the assignment of the bands to N_2.

The accompanying illustration shows the bands as photographed on a glass prism spectrograph with a dispersion of around 10 A./mm. A spectrum of a discharge through air showing only the First and Second Positive bands of N_2, with a little N_2^+, is given for comparison. The new bands are degraded to the red and show several heads, having a complex rotational structure rather similar in general appearance to that of the Third Positive bands of carbon monoxide ($^3\Sigma \rightarrow {}^3\Pi$). Three of the heads of the three strong bands have been carefully measured and are given in the table, with *provisional* assignment of vibrational quantum numbers. The head of the 4,166 A. band falls on a strong grouping of lines (due to perturbations) in the (2,6) Second Positive band.



v', v''	λ	ν
0,0	4166·5	23994
	4171·6	23965
	4178·3	23927
0,1	4432·0	22557
	4438·2	22525
	4446·0	22486
0,2	4729·2	21139
	4736·0	21109
	4744·2	21072

Weaker bands at about 5,063 and 5,440 A. may be the (0,3) and (0,4) bands respectively, but overlapping by weak First and Second Positive bands of N_2 renders accurate location of heads difficult. There is also weak band structure around 5,575 A., which *might* be the (1,5) band.

The separation between the (0,0) and (0,1) and between the (0,1) and (0,2) bands is 1,440 and 1,416 cm.$^{-1}$ respectively. The corresponding differences for the $A^3\Sigma$ state of N_2 are 1,432·5 and 1,404·7. The present measurements should be accurate to 1 or 2 cm.$^{-1}$, and, unless there is a big difference between the positions of the origins and heads of the bands, it can be assumed that $A^3\Sigma$ is not involved.

It seems surprising, at first sight, that a readily observable system of N_2 in the blue should have been overlooked for so long, but it may be pointed out that the bands are overlaid by the much stronger Second Positive system, which were not themselves accurately measured before 1940[2]. The discovery of a new system of N_2 involving two new molecular states, probably of fairly low energy, gives some support for the view recently expressed by Gaydon and Penney[3] that the non-crossing rule, that potential curves of molecular states of the same species cannot cross, may hold for nitrogen, and thus that the dissociation energy is higher than the value of 7·38 electron volts in common use.

In addition to the new band system, a single band, degraded to the violet with heads at 5,333·5, 5,327·3 and 5,320·0 A., also appears in spectra of the ozonizer discharge and in a low current-density induction-coil discharge at high pressure through nitrogen. This may correspond to still another system of N_2, but the assignment is less certain.

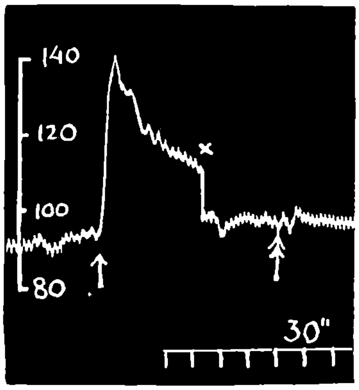
Pressor Substances in Urine and Plasma from Normal and Hypertensive Subjects

NORMAL urine contains a pressor principle[1] which has been identified as *iso*-amylamine[2] and found t account for most of the urine pressor action.

If normal urine is concentrated *in vacuo* at neutra or slightly acid reaction and quantitatively extracte with ether at *p*H 9–10, the ethereal extract con sistently contains a pressor substance which conform in its properties with *iso*-amylamine. A strong presso action was generally obtained with an amount o extract corresponding to 100 ml. normal urine Similarly prepared extracts from the urine of te hypertensive patients (essential hypertension an chronic nephritis) contained much less of this sub stance when tested on the cat's blood pressure. Thu the extract of 100 ml. urine in some cases was com pletely inactive (see accompanying figure). It has been reported that the urine pressor activity does not differ significantly in extracts from normal and hypertensive subjects[3], but also that urine from arteriosclerotic and hypertensive patients contains less of the pressor substance, though no quantitative data have been given[1,2].

No evidence has been obtained in our experiments for the presence of significant amounts of other ether-soluble pressor agents, such as tyramine. This is in accord with other observations[4]. Ether extracts of acidified urine may contain small amounts of a pressor substance, differing from *iso*-amylamine.



CAT'S BLOOD PRESSURE. ↑ ETHER EXTRACT OF 100 ML. NORMAL URINE. ↑ ETHER EXTRACT OF 100 ML. URINE FROM PATIENT WITH ESSENTIAL HYPERTENSION.

Extracts of heparine venous plasma from normals and hypertensives were prepared by precipitation with alcohol and concentrated *in vacuo*, the residue being extracted with ten volumes of methyl alcohol, which was distilled off. When tested on the cat's blood pressure, normal plasma extracts regularly produced a moderate rise in pressure in amounts corresponding to 25 ml. plasma, whereas plasma extracts from hypertensive patients usually produced a much smaller action, in both cases preceded by a short lowering of the blood pressure. The test animals were atropinized and had received 0·15 mgm. ergotamine tartrate per kgm. in order to exclude the action of the buffer nerves.

The results suggest important changes in the production or excretion of biologically active metabolites in essential hypertension.

Determination of the Osmotic Pressure of Biological Fluids

IN 1938 Blegen and Rehberg[1] described a method for determining the osmotic pressure of biological fluids based on the measurement of the initial rate of outflow of water from one solution through a semipermeable membrane into another solution of somewhat higher osmotic concentration. As semipermeable membranes they used small collodion bags impregnated with copper-ferrocyanide[2]. The collodion bag is alternately filled with the unknown fluid and with a solution of sodium chloride of known strength, and is connected to a piece of capillary tubing (0·2–0·5 mm. internal bore) which is bent at right angles so as to form a longer, horizontal arm of about 15 cm. length carrying a millimetre scale. When the bag containing the unknown fluid or the sodium chloride solution is immersed in a sodium chloride solution of higher concentration, the meniscus begins to move, and the rate of movement, which is taken to be proportional to the concentration difference, is determined at intervals.

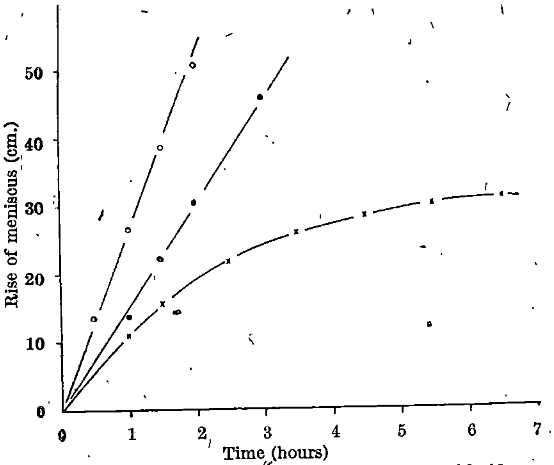
It was thought that this simple method might provide a suitable technique for detecting the presence of added water in milk. Unfortunately, on careful examination of the method I was unable to substantiate some of the claims made by Blegen and Rehberg for it, and this note is intended for the guidance of others who may be attracted by the apparent simplicity and ease of the procedure described by the Norwegian authors.

Batches of membranes were prepared by the method described by Blegen, and standardized by determining the rate of movement of the meniscus for 0·80 against 1·00 per cent sodium chloride solution. Only membranes which gave a constant rate of movement for at least 40 minutes were used in further work. A series of membranes was selected varying in the rate of movement from 1 mm. to 20 mm. per minute, using capillaries of 0·25 mm. internal bore. With all these membranes it was possible to determine the concentration of sodium chloride solutions with great accuracy, thus far confirming Blegen and Rehberg's findings. Difficulties arose, however, as soon as milk was chosen as the 'unknown' fluid. A rapid movement of the meniscus was observed, even when a bag filled with milk was immersed in salt solution isosmotic with the milk.

Blegen and Rehberg state that with serum the results of their method were "of the same order of magnitude as with Hill's (thermo-electric) method", but only one example in which actual comparison was made between the two methods is cited. The results were in good agreement, but the value of 0·179 n = 1·05 per cent NaCl is outside the usual range of values for human serum of 0·90–0·97 per cent NaCl[3]. In tests with sera prepared from cow's blood, I found that the results obtained by the Blegen and Rehberg method were always appreciably higher than those of the freezing point test which was used as method of comparison. Thus, a serum with a freezing point corresponding to 0·94 per cent sodium chloride gave a value of 1·02 per cent sodium chloride when tested by the water permeability method.

The difficulties encountered with milk and serum led to a study of simpler systems, using a modified experimental arrangement in which collodion bags were connected to vertical capillary tubes of about 60 cm. length and of approximately 1 mm. internal bore. Isosmotic solutions of sodium chloride, urea, and sucrose were tested against each other, and the accompanying graph shows results typical of these experiments.

An apparent 'osmotic pressure' between solutions which were, in fact, isosmotic was observed with all membranes, even with those which showed little movement of the meniscus in the standard test with sodium chloride solutions mentioned above. The anomalous behaviour finds its explanation in the fact that the membranes are not truly semipermeable,



All solutions isosmotic to 0·88 per cent sodium chloride.

	Inside membrane	Outside membrane
×	NaCl	Urea
●	Sucrose	NaCl
○	Sucrose	Urea

but allow the slow diffusion of small molecules and ions. The more diffusible substance will then increase the osmotic concentration on the opposite side of the membrane, thus causing a flow of water in that direction, with the result illustrated in the graph. As the osmotic forces in milk, serum and other biological fluids are due to a variety of substances in addition to sodium chloride, anomalies of the kind observed are only to be expected with these fluids. Unless a method can be designed by which truly semipermeable membranes can be prepared with ease —and in this I did not succeed—the technique of Blegen and Rehberg appears scarcely commendable for biological work.

In conclusion, brief mention should be made of the interesting possibility of the occurrence of membranes of the 'slowly-permeable' type in living organisms. The graph illustrates clearly the considerable forces at play between isosmotic systems separated by this type of membrane.

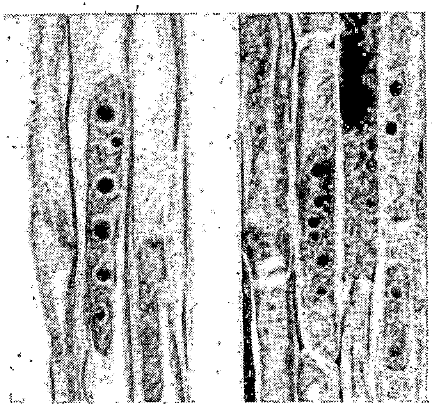
Nucleoli in *Agropyron repens*, Beauv.

DURING an investigation of the shoot apex of *Agropyron repens*, Beauv., longitudinal sections were obtained in which the nucleoli stood out in strong contrast to the rest of the nucleus. When this was noticed, counts were made and the maximum number per nucleus was found to be six. Photograph *A* shows the six nucleoli in the nucleus of a developing sclerenchyma cell, while *B* shows the six in the nucleus of a procambium initial. Sometimes there was a suggestion that the nucleoli were of three sizes, a large pair, a slightly smaller pair and a small pair, though this was not at all definite, and the appearance shown in *A* and *B* seemed more common (? some nucleoli only partly represented in the sections).

Observations were easiest on the cells of the developing strands and the associated sclerenchyma because the nuclei here are considerably elongated and there is consequently less tendency for the nucleoli to fuse together. Since these nuclei are about five to eight times as long as they are wide, it is often possible to have all six nucleoli well separated from each other and all in focus at the same time, making it fairly easy to observe and photograph them.



A B

NUCLEOLI IN *Agropyron repens*, BEAUV. (× *c.* 1000).

The possession of six nucleoli by *Agropyron repens* is interesting, first, because it accords with the hexaploid somatic chromosome number of 42 (Avdulov[1], Peto[2], although they also record plants with 28, 34 and 35 chromosomes), and secondly, because it is paralleled in the hexaploid wheats *Triticum vulgare* and *T. Spelta*[3], which have a somatic number of 42 and also possess six nucleoli.

Synthetic Rubber

CLEARLY Dr. Naunton is acutely sensitive, justifiably, about synthetic rubber. His review of my book in NATURE of December 26, p. 751, is unfair in several respects. Undoubtedly, there are errors in the book. I am grateful to have them pointed out. But why add to them ?

Dr. Naunton says : "The author apparently is under the impression that isobutylene and butadiene will co-polymerize in almost any proportions in which the experimenter mixes them, but this is, of course not the case". On several pages I state that butyl rubber is a co-polymer of olefine with a small amount of diolefine.

He scorns my account of handling butyl rubber. Yet the latest official directive for handling butyl rubber states : "The following precautions will greatly enhance the ease of handling butyl rubber on the mill : (*a*) mill roll temperatures at the outset should be warm, 105 deg. F. to 115 deg. F. When the band has been formed, and during mixing, roll temperature should be kept as low as possible". Am I so far wrong ?

Dr. Naunton dismisses too lightly the part chemical concerns are playing in the United States productions. He is evidently a scientific 'Bourbon' in his underestimation of the intelligence of the 'general reader'

Three out of thirteen references on "Copolymerizaion" are to U.S.S.R. work; two to British work. As the subject is considered in relationship to synhetic rubbers, is this so unbalanced as to justify Dr. Naunton's querulousness ?

An official directive on Hycar OR, with Dr. Naunton's name attached, does not differ substantially from my own comments. I am somewhat mystified by the criticism.

I reiterate my belief that the industrial welfare of Great Britain can only be guaranteed by achievement based on hard work, and not merely by disussion and buying licences.

"Spinney Corner",
Bassett Avenue,
Southampton.

HARRY BARRON.

I CANNOT agree that the review of Dr. Barron's book was unfair. It was critical but definitely not unfair.

It is true that Dr. Barron states in the book that he commercial product known as butyl rubber conains only a small amount of diolefine, but the riticism was levelled at the general case of interpolymerizing of isobutylene and diolefines, where mportant generalizations have been missed and miseading facts and figures have been quoted. Dr. Barron would be well advised to put more trust in xperimental work and less in published information. The *fact* remains that butyl rubber runs smoothly on cold mill but breaks up on a hot one.

I think Dr. Barron is confusing intelligence with nowledge. The 'general reader' is often far more ntelligent than the chemist, but no amount of ntelligence without chemical knowledge will enable im to appreciate structural formulæ.

I would remind Dr. Barron that I was not querulous" about the emphasis which had been iven to U.S.S.R. work on co-polymerization but on he narrower field of the constitution of co-polymers. The work of Hill, Lewis and Simonsen published in 939 should surely have been mentioned.

In Dr. Barron's comment about Hycar OR, we ee at last our different points of view. Dr. Barron wishes to paint a picture in which effect is obtained t the cost of only substantial accuracy, but a textbook as distinct from journalism is not a picture but sharp photographic reproduction of facts.

Manchester.

W. J. S. NAUNTON.

Future of University Education

THE British Association report on Post-War University Education (see NATURE, December 19, 1942) ontains some excellent suggestions. The plea for he further extension of residential facilities at the modern universities, for example, is fully justified by xperience in the University of Reading, which was pioneer in this field. Nor will anyone dissent from he Committee's premise that a scientific career hould be broadly based upon the "humanities". ne must, however, disagree with the conclusion hich is drawn that a study of the "humanities" hould be included as an essential part of the univerty 'honours courses' for science students. All eshmen will, before entering their honours course, ave enjoyed some six or seven years of secondary ducation, and it is in the secondary school that the ssential foundations of a general education should ave been laid. The period available is ample, if isely used, to stimulate any intellectual interests of hich the student is capable, and of laying a foundation upon which he should be able to develop those interests by leisure reading.

If, in point of fact, the schools have been betrayed (whether by the pressure of the university scholarship system, or other cause) into too great specialization, so that the present undergraduate is less widely read than his predecessors, the remedy is to be found by an overhaul of the school curriculum rather than by inserting irrelevant subjects into university courses. Omniscience is no longer a possible educational objective, and there must be some stage at which a science student begins to concentrate upon those special subjects, the mastery of which will enable him to make his specific contribution to the welfare of society. I suggest that this point comes naturally at the beginning of his university career. A wise tutor will, no doubt, encourage his students to a wide course of reading in their leisure time, and to a reasonable participation in undergraduate societies; but the student should not be distracted from his main objective by having to face an examination in any non-related subject.

There is one point, however, on which I believe the Committee has moved on to very dangerous ground. It is, perhaps naturally, expressed more clearly in the article in NATURE on the report than in the more cautious words of the Committee itself. I quote the relevant paragraph.

"It is therefore with a feeling of deep satisfaction that we note the Committee's insistence on training for world citizenship in all faculties, pass and honours, of our universities. . . . Social studies and the humanities must play a certain part in the training of all students. This applies especially to science students, for it is almost axiomatic that, in present circumstances, a man might gain a first-class degree in science and be no more appreciative of the essentials of world citizenship than any less fortunate individual who has not gone so far as through a secondary school."

To suggest that a graduate is, or ought to be, a higher type of *citizen* than the man whose gifts do not lead to a university education is to misunderstand the nature of citizenship in a democratic community. It has a totalitarian ring about it, and is calculated to arouse indignation in many manual workers who feel, and rightly so, that their conviction of what constitutes the basis of a sound social order is entitled to as much respect as that of the intellectual. I hear from colleagues who have recently been holding discussion groups with the Forces that similar pronouncements by our 'intelligentsia'—who are apt to take it for granted that high intellectual training is a pre-requisite for leadership in the new age—is already causing serious resentment.

Society will choose its own leaders; wisely, we may hope, but certainly for qualities in no way connected with academic distinction, even in sociological subjects. But society will also need, for its great task of restoration, men and women of high ability and intensive training in each of the sciences—and the humanities, too—and will welcome them, not as superior world citizens, but for the special contributions which their scientific education enables them to make. The education and training of these experts is the special function of the university, from which it should not be deflected. For the undergraduate who has the ability which justifies an honours course in science, the eager pursuit of the training which is to fit him for this task is his best form of social service.

University of Reading.

J. A. CROWTHER.

SOCIETY OF AGRICULTURAL BACTERIOLOGISTS

THE annual conference of the Society of Agricultural Bacteriologists, held at the University of Leeds during August 27–29, 1942, reflected the influence of war-time conditions. Several members of the Society were unable to leave their duties in order to attend the conference, and the papers, particularly those concerned with dairying, showed that problems of immediate practical importance are being investigated. The field covered by the discussions was nevertheless wide and afforded an index of the activities of a society which exists with the object of advancing the study of general, agricultural and related branches of bacteriology.

A contribution to the bacteriology of sewage disposal dealt with the nitrifying activity of biological film from percolating filters. The activity was measured by inoculating an ammonium sulphate-calcium-carbonate solution with a dilute suspension of film, aerating the cultures in inverted conical flasks, and determining the rate of production of nitrite and nitrate. Nitrifying activity was found to be influenced by season, depth below the surface of the filter and the rate of treatment of sewage. Film produced in ordinary single filtration acted differently from film obtained in the process of alternating double filtration, in which two filters are operated in series, with a periodic change in the order of flow.

In the disposal of certain industrial wastes the activity of the sulphate-reducing organism *Vibrio desulphuricans* may require control. It has been shown that this microbe may be easily suppressed by the relatively simple and inexpensive method of adjusting the hydrogen ion concentration to less than pH5 or more than pH10. An illustration of the practical application of this principle was cited. A pond used for the reception of a waste containing 20–30 per cent of fatty matter and 3–4 per cent of sulphate (as calcium sulphate), at the rate of about forty tons a week, created a nuisance in the locality owing to the evolution of hydrogen sulphide. The pH value of the water was brought to 3 by adding sulphuric acid and the trouble was eliminated.

Shellfish which have been subjected to the process of self-purification in tanks of clean sea water have recently provided a problem. On arrival at inland markets they sporadically harbour large numbers of coliform organisms, and the suspicion that purification has been inadequate naturally arises. Investigation showed, however, that this occurrence is due to multiplication during transport of coliform bacilli which have no sanitary significance. With the object of finding a rapid method which would differentiate typical *Bacterium coli* from other members of the group, the modification of the Eijkman test using MacConkey's broth was re-investigated. Taking the production of acid and gas as the differential criterion, an incubation temperature of exactly 44° C. afforded the best separation of the types. In an examination of 1881 cultures derived from a variety of sources, 97·5 per cent of the typical *B. coli* produced acid and gas at 44° and only 5·2 per cent of the other coliform strains did so.

The coliform group in its relation to dairy products was also discussed. It has been found that the presumptive test for the presence of these organisms when applied to milk gives a lower estimate of the coliform population than when applied to water. Abnormal gas formation in factory-made Cheddar cheese was attributed to coliform bacilli introduced into pasteurized cheese milk from such sources as coolers and pipe lines. While various types of this group were isolated, typical *B. coli* predominated at all stages in the making and ripening of the cheese examined and appeared to be responsible for the majority of cases of gas production.

Bacteriophage active against streptococci, which may be responsible for difficulties in the making o Cheddar cheese, has now been successfully demonstrated in high dilutions prepared from cheese up to 3½ months old.

The resazurin reduction test is receiving much attention as a means of grading milk. One pape described the chemistry of resazurin and gave practical hints on the test. Other two papers dealt with the 10-minute resazurin test which is now used fo the rapid recognition of unsatisfactory milk, a product which has become an important problem unde war-time conditions. According to the colour of the milk-dye mixture after 10 minutes at 37° C. milk may be classified in three categories: (1) suitable fo the liquid milk market, (2) suitable for manufacture only, and (3) unacceptable for any purpose. The results usually agree with those of methylene blue reduction and are obtained in a shorter time. Othe rapid tests, such as those utilizing titratable acidity pH, clot formation on boiling, alcohol precipitation smell and taste, have been found to be less suitabl for use on the receiving platform of creameries. A fourth paper presented evidence that the resazurin test, when performed at 18° C., gives within two hour a reliable indication of the keeping quality of milk Samples of really poor keeping quality can be detected within 30 minutes by the 18° test.

Mastitis of the dairy cow was discussed in thre contributions. A comparison of diagnostic method applied to a large number of samples led to the conclusion that for the detection of sub-clinical mastiti a combination of two indirect tests, the determinatio of the leucocyte content and of the electrical conductivity of milk, is superior to the isolation an identification of the infecting organism in reliability speed and cost of materials. Milk from an infecte quarter has an abnormally high cell count and largely owing to an excess of chlorides, a high conductivity. The standards adopted to differentiat between normal and infected milk were 500,000 cel per ml. and a conductivity of 49·0 × 10^{-4} mhos.

In the second paper on mastitis, which describe field observations on the control of the disease methods of cultivating *Streptococcus agalactiæ* wer compared, and evidence was presented to show that factors such as unsuitable milking machines have a important influence in raising the infection rat The third paper dealing with mastitis described broth containing peptone, yeastrel, mannitol, æsculi and hippurate which permits *S. agalactiæ* to displa the majority of its differential characters. It is thu possible to identify the organism by preparing single culture in the composite medium.

Other contributions to the proceedings dealt wi methods of increasing the heat resistance of th spores of a putrefactive anærobe and with the contr of moulds (Penicillium and Mucor) in meat pies b changing the methods of manufacture.

In spite of difficulties due to the War, this conferen was most successful and did not depart from th trend towards greater variety of interests which ha characterized annual meetings of the Society.

BIRDS AND BUTTERFLIES

By Dr. C. B. WILLIAMS

Rothamsted Experimental Station

THE extraordinary mimetic resemblances which exist between certain apparently edible species of insects and other distasteful species, which are found in the same neighbourhood, reach their highest development in the Rhopalocera or butterflies. The resemblances are purely external and frequently confined to the upper surfaces of the wings only. They are obviously meant to deceive an eye.

If this mimicry has been brought about by natural selection of smaller or larger variations because they are of survival value to the mimics, there must be some enemy whose eye is deceived, and further, in view of the perfection of many of the resemblances, it must be sometimes not deceived by the less perfect resemblances.

Undoubtedly the chief death-rate of butterflies is n the egg, caterpillar and chrysalis stage, but these resemblances which we are now considering are in the adults, so that we have to search for an enemy which can exert a considerable selection pressure in the short period between the emergence of the butterly from the chrysalis and the time that most of ts eggs are laid; for after this latter no selection is of survival value to the race.

We need, therefore, a sharp-eyed predator which s active by day and which sees the butterflies when their upper surfaces are exposed, that is, probably when in flight. Birds are the obvious choice, but when the suggestion was first critically examined it was found that the evidence of bird attack on butterlies was very small. Quite experienced field naturalists commented on its rarity.

In the subsequent search for evidence two promising ines of work have been in progress. At an early stage field experiments were made by offering to tame or wild birds butterflies that were believed to be palatable or distasteful, together with mimics of the atter.

More recently, progress has been made by the discovery that the butterfly wings often show definite marks where they have been nipped by the beak of a bird. In these cases, of course, the butterflies have been fortunate enough to escape. The marks may be so definite that the size and angle of the beak may be measured and a close guess made at the group or even species of bird that caused the injury.

Prof. G. D. H. Carpenter has been associated with these lines of study for many years and in two recent papers*, one prepared from notes left by the late C. F. M. Swynnerton, he brings forward much new evidence on both counts.

On the problem of the relative frequency of beak marks he shows that in more than ten thousand museum specimens of the distasteful genus Euploea, 123 (1·15 per cent) showed beak marks on the wings; n more than six thousand African Danain butterflies, also distasteful, 117 (1·05 per cent) had marks; but in more than seven thousand African Colotes spp., a quite edible genus, only 11 (0·15 per cent) were marked.

The inference is, as Prof. Carpenter points out, not that the distasteful species are more frequently bitten by birds, but that, being bitten, they more frequently escape or are allowed to escape.

A comparison was also made between 550 distasteful Danaine models which showed 17 individuals with beak marks, and 340 Nymphaline mimics, of which there was only a single one with a beak mark.

In an appendix to this paper, it is also shown that of 613 distasteful butterflies from all parts of the world which had beak marks, 133 or 21 per cent had evidence of more than one attack, while of 179 edible butterflies with beak marks only 21, or 11·7 per cent, had evidence of more than one attack. The difference is statistically significant.

Prof. Carpenter's conclusion, which seems to be justified, is that distasteful (aposematic) species are more frequently found with beak marks because they "live to fight another day", owing to not having been eaten by their bird enemies even when they have been seized.

The summary of Swynnerton's field experiments is a mine of interesting information. The main portion deals with the behaviour of birds towards butterflies of different species which were 'planted' in positions visible to the birds but prevented by various means from flying away. Twenty-two such experiments are described and the results are very striking. Time and time again the more distasteful species are either completely neglected, or, even more convincingly, carefully examined at first and then neglected. The more palatable species, on the contrary, were eaten in very high proportions. The distinction between palatable and distasteful is not absolute but comparative, and very hungry birds will eat relatively distasteful species, while replete birds will require to be tempted by a particularly choice morsel. Other things being equal, a hungry bird will eat a large butterfly in preference to a smaller one.

In one example given (Section C, Experiment 1), 84 butterflies were exposed, and after five hours 45 had been eaten. Among the butterflies were 7 Danains (aposematic), none of which had been touched, and 24 *Vanessa cardui*, of which 22 had been eaten.

In other experiments the birds were shown to be definitely deceived by mimics of aposematic species.

There is no doubt that a considerable body of evidence has been brought forward to show that birds are important and critical enemies of butterflies, that they have to learn by experience the appearance of distasteful species, and that once having learnt this they are frequently deceived by mimetic resemblance.

UTILIZATION OF GLASS

PROF. W. E. S. TURNER read a paper on "New Uses for Glass" before the Royal Society of Arts on January 20. He briefly traced through history the development of the use of glass from its main original use for decorative purposes to its ever-widening use as an essential material for utilitarian purposes. No period has seen more fruitful advances than the past fifteen years.

Systematic scientific investigation has resulted in providing us with glasses having a density from 2 up to 8: a coefficient of thermal expansion varying at least thirty-fold; a range of thermal endurance such that objects made from some glasses can be heated to glowing and quenched in water without fracture; a range of load-bearing capacity up to six and even ten-fold; electrical resistance varying up to at least ten thousand-fold; while the non-corrodible character of modern types of glasses is such that it can and has replaced stainless steel, offers resistance to steam at high temperatures and pressure, to strong acids and many liquids which are chemically corrosive of other known materials and is without any action on the most sensitive of physiological, biological and chemical preparations.

Sheet glass is now drawn continuously in the flat state more than one hundred inches wide; plate glass is, by the latest British process, not only rolled continuously some 12 ft. wide, but is simultaneously ground and polished on both sides. Thousands of different articles such as bottles, jars, tumblers and drinking vessels of all kinds, even complicated articles like jugs with handles and wine glasses with feet, are now produced entirely by automatic machinery; half a million electric light bulbs per day are turned out by automatic machines and miles of glass tubing of various kinds and diameters. Glass can be converted into flakes and drawn into threads as fine as silk at the speed of some six thousand feet per minute, with numerous uses in the production of yarn and woven textiles, as filtering mediums and for insulating purposes.

The modern processes of tempering glass have tremendously increased its safety factor against breakage and made its use possible against extremes of heat and cold, for transparent pressure chambers, for high-power electric insulators, a base on which to spray a metal for grids to form electric radiators, for the tops of hot stoves, and for general constructional purposes, including doors provided with metal fittings. The combination of layers of glass with very thin layers of transparent plastic materials has given laminated glass for transport vehicles and, when used in multi-layers, bullet-resisting glass, as used in tanks and aeroplanes.

The advances in sealing glass to metals have made possible the construction of metal filament electric lamps, cathode ray tubes and radio valves; mercury arc rectifiers, in glass envelopes and operating with electrodes at high temperatures, are now in operation in many transformer stations.

Glass can also be coloured for the transmission of light and radiation; colourless glasses will transmit X-rays with high efficiency, whereas lead- and barium-containing glass provides screens for protection against X-rays. Glasses are made with a high transmission for ultra-violet light; and deeply coloured glasses can be made which transmit nothing but ultra-violet light on one hand or infra-red on the other.

FORTHCOMING EVENTS

(Meeting marked with an asterisk is open to the public)

Saturday, February 6

Nutrition Society (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 11 a.m.—Conference on "Nutrition in Pregnancy".

British Rheologists' Club (at the Royal Society of Arts, John Adam Street, Adelphi, London, W.C.2), at 2.15 p.m.—Dr. R. N. Haward: "The Extension and Impact Resistance of some Plastic Materials".

Geologists' Association (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 2.30 p.m.—Mr. F. A. Bannister: "The Determination of Minerals by X-Ray Methods".

Monday, February 8

Institution of Chemical Engineers (joint meeting with the Chemical Engineering Group, the Yorkshire Section of the Society of Chemical Industry, and the Leeds Area Section o the Institute of Chemistry) (in the Chemistry Lecture Theatre The University, Woodhouse Lane, Leeds), at 6 p.m.—Dr. A. H. Jay "The Application of Crystal Analysis to some Chemical Engineerin Materials".

Tuesday, February 9

Royal College of Physicians (at Pall Mall East, London, S.W.1) at 2.15 p.m.—Prof. M. Greenwood, F.R.S.: "Medical Statistician from Petty to Farr" (Fitzpatrick Lectures, 1).

Royal Institution (at 21 Albemarle Street, London, W.1), a 3 p.m.—Sir Lawrence Bragg, F.R.S.: "The Solid State", (iii) "Minus minus Compounds".*

Illuminating Engineering Society (at Gas Industry House, Grosvenor Place, London, S.W.1), at 5 p.m.—Contributions on "Th Effectiveness of Lighting, its Numerical Assessment", to be followe by a Discussion.

Wednesday, February 10

Royal Society of Arts (at John Adam Street, Adelphi, London W.C.2), at 1.45 p.m.—Mr. R. G. Glenday: "Location of Industry".

Royal College of Physicians (at Pall Mall East, London, S.W.1) at 2.15 p.m.—Prof. M. Greenwood, F.R.S.: "Medical Statistician from Petty to Farr" (Fitzpatrick Lectures, 2).

Institution of Electrical Engineers (Installations Section (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m —Discussion on "The Use of Electricity in relation to Fuel Economy' (to be opened by Mr. R. H. Rawll).

Friday, February 12

Royal Institution (at 21 Albemarle Street, London, W.1), a 5 p.m.—Dr. G. M. B. Dobson, F.R.S., and Dr. A. R. Meetham "The Air we breathe in Town and Country".

Saturday, February 13

Iron and Steel Institute (joint meeting with the Sheffiel Metallurgical Association, the Sheffield Society of Engineer and Metallurgists, and the South Yorkshire Section of th Institute of Chemistry) (at the Royal Victoria Station Hote Sheffield), at 2.30 p.m.—Mr. H. T. Shirley and Mr. E. Elliott: " Critical Consideration of some Applications of the Spectrograph t Steelworks Analysis".

APPOINTMENTS VACANT

Applications are invited for the following appointments on o before the dates mentioned:

Lecturer in Mining—The Principal and Clerk to the Governin Body, Wigan and District Mining and Technical College, Wiga (February 13).

Lecturer in Chemistry—The Principal and Clerk to the Governin Body, Wigan and District Mining and Technical College, Wiga (February 13).

Graduate Master or Mistress to teach Mathematics an Geography in the Harrogate Technical Institute—Mr. W. E. Jalland, The Secretary to the Managers, Municipal Offices, Harrogat (February 15).

Chair of Mining—The Secretary, The University, Edmund Stree Birmingham 3 (March 1).

Instructor in Beekeeping—The Education Officer, County Hal Wakefield (March 1).

Sir Dorab Tata Reader in Pharmaceutical Chemistry in t Department of Chemical Technology—The Registrar, University Bombay, Bombay, India (April 15).

Head of the Mining Department—The Principal, Coun Technical College, Mansfield, Notts.

Lecturer in Electrical Engineering—The Clerk to t Governors, South-West Essex Technical College and School of A Forest Road, Walthamstow, London, E.17.

POST-WAR CIVIL AVIATION IN GREAT BRITAIN

THE debate in the House of Commons upon the policy of the Government towards the future of civil aviation, which took place on December 17, made public facts that are disturbing. They should be given much more attention than the complacency of the Air Ministry representative's reply suggests that they will receive. Indeed, the relatively small amount of comment which has been published shows that the matter is in danger of being put aside as of little importance except in connexion with plans for reconstruction, a topic which is still unfortunately regarded by many as too speculative to be of immediate importance.

There was a certain lack of perspective in the debate in that an unduly large proportion of the time was taken up in the airing of minor matters concerning the internal management of British Overseas Airways, the company that now exercises a monopoly control over civil aviation under British jurisdiction. Such matters as disciplinary troubles with the staff, and the fact that the Prime Minister's recent flights have been made in charge of pilots not of British nationality were discussed at considerable length. The Joint Under-Secretary of State, Captain Harold Balfour, in his reply, made it quite clear that the Air Ministry does not feel disposed to interfere in such cases, maintaining that, in effect, although these several mismanagements are admitted, they are not sufficiently serious to call for such a drastic step as the removal of the company's Board or even an individual member of it, which is the only real power that the country has in return for paying a subsidy of several million pounds a year.

The much wider and more far-reaching question which arose was that of the Government's attitude towards the present-day development of civil aviation, from the point of view of the situation that will arise in the immediate post-war period. An inter-departmental committee issued an interim report about eleven months ago, in the form of a series of policy questions to the Cabinet. Nothing further appears to have been done since, as until these questions of policy are settled, the committee obviously cannot continue to function on its details.

Meanwhile the gradual absorption of the world's air routes by the American companies is proceeding, sometimes by arrangement with Great Britain, more often because they are the only competitors in the field, but always because we, through lack of an organization and equipment, are not in a position to cater for the demand where it exists.

American air lines have a monopoly in the Pacific and the South Atlantic ; in the North Atlantic they are two to one (our one is run by a British air line but with American machines), in Africa civil air transport is being operated by Americans, and it is reported there will shortly be American air lines operating from Aden and India. This position of inferiority is due partly to the initial lead of the United States in matters of air transport in pre-war days, but it is aggravated by the war-time arrangement that British policy has been to concentrate on the design and production of the smaller aircraft, leaving the larger ones to the United States. This is logical from the delivery point of view, as the large long-range machine can be sent over to the various war centres under its own power, while the small fighter or medium bomber would absorb shipping space and be under greater risk of loss by submarine attack. It is unfortunate, however, in that the large machine is the type that is required for civil air transport, and thus the United States is able to divert a proportion of her output to civil purposes as required, and is gaining experience, and already using it, to design and produce newer and larger transport machines.

Nor does the discrepancy end with this. An air transport concern having a constant supply of newly designed machines and engines must not only be functioning with the utmost efficiency, but also be able to train the personnel in the use of these, and thus build up an organization of skilled staff. British Overseas Airways has no such advantages. Nearly half its equipment is earlier American, the rest being partly obsolete British civil transport machines, or the more modern of them are R.A.F. rejected types, designed for war purposes and converted so far as practicable to civil transport needs. Several of these are fitted with American engines. Actually there are seventeen types of aircraft with fourteen types of engines. The inefficiency, from the point of view of cost and man-hours involved in maintaining such a collection, must be staggering. Also no experience in the use of the more modern machines is being gained, a loss both from their own operational point of view, and that it will not be available to designers of civil aircraft and engines for the post-war period. This is the present position and, so far as is known, the Ministry of Aircraft Production has no plans in hand, nor has it placed any orders for either aircraft or engines specifically designed for civil air transport.

A concrete suggestion for the immediate improvement of this state of affairs, based on partial and rumoured promises, was put forward by Mr. Perkins in the course of the debate. It was that twenty "York" aircraft (a large bomber with a body re-designed for air transport purposes) or else a similar number of another machine outcast by the R.A.F., which he called the "W", together with ten "Sunderland" flying boats, be handed over at once to British Overseas Airways and also the American "Lodestars" now in our possession under the Lend-Lease Act. These should be fitted with the best of the modern developments in variable-pitch airscrews in order to promote safety and maximum efficiency in operation. Financially it would probably be an economy, as it would allow of the scrapping of an equivalent accommodation in old and obsolete aircraft which must now be operating inefficiently, and the reduction in the number of types would economize on maintenance costs. It would give the staffs experience in handling more up-to-date equipment, would help to bridge over the period when inevitably no new civil aircraft will be forthcoming, and would enable us, when the necessity arises, to approach the problem of coming to an arrangement with the United States on more equable terms.

For the future, the long-term policy advocated was to take civil aviation away from the Air Ministry, the principal interest of which, quite rightly, is to develop and maintain the standard of the R.A.F. equipment. A committee should be set up to survey the whole question of civil aviation—not only air transport—with instructions to report quickly, say in three months time. The present monopoly given to one concern only should be abolished, and a healthy sense of competition allowed to function. This could be controlled, giving certain fields to specialist firms to avoid overlapping, without giving complete monopoly to any one. The Government should at once initiate the commencement of the design of three aircraft and three engines definitely suited to three broad types of civil air transport work.

In this respect it is interesting to note the report of the American Maritime Commission, published nearly five years ago. Although not a body primarily interested in aviation, the Committee expressed the opinion that large aircraft are already capable of superseding luxury liners of the *Queen Mary* type. It envisaged a large flying boat, to-day a technical possibility, six of which could carry per year more passengers on the Atlantic crossing than did the *Queen Mary*, and moreover the trip would take ten hours or less instead of five days. The standard of comfort need be no less than we expect upon a night 'sleeper' on the London-Scotland railways.

From the political aspect, the possession of a large air transport organization would be of the greatest help. Rapid travel would expedite that personal contact between the really big executives that will be needed when the question of rearranging the democratic government of the world has to be faced. Many speakers during the debate hoped for the possibility of the establishment of the freedom of the air when that time comes. This 'open sky' policy should follow the lines of the accepted freedom of the seas. Free and unrestricted flight to all points should be given. No small nations should be allowed to obstruct by prohibiting flights over their territory. Unrestricted use of airports, these maintained with an agreed standard of equipment, lighting for night flying, and other such safety devices, must be provided by all nations. At the end of this War, with the Great Powers in a position to dictate, in a benevolent way, to the smaller States, the psychological moment for such an innovation would seem to have arrived.

The reply of Capt. Balfour, on behalf of the Government, was far from reassuring. Apart from answers to the several minor criticisms that were outside the question of broad policy, his speech was mainly a defence of having put the whole of our effort into R.A.F. equipment, concentrating on "first things first", and consequently our inability to get "more than a pint out of a pint pot". He welcomed the taking over of the British African air route by Pan-American Airways, disguised as part of the U.S. Army Air Transport Command, on the grounds that it is helping in our combined war effort. Exactly what the situation will be when the War ends, if the proposed freedom of the air is adopted, he did not mention. Pan-American Airways will have a complete monopoly of this, and possibly other Middle Eastern air routes, with machines, equipment, and personnel suited to the conditions as discovered by their experience. Apart from sentiment, Great Britain cannot show any claim to replace them. Without an alteration in our present policy, we shall certainly not be able to offer to the localities a better or even so good a service, lacking, as we shall, both experience and specially developed equipment.

The crux of the whole matter of policy appears to be that of the proportion of the aeronautical effort in Great Britain which is allowed to be devoted to civil aviation, particularly that part of it which is directed towards the long-range view of post-war requirements. The British allocation during 1942 was £5,000,000 given to one monopoly company, and a promise of a very small number of converted bombers and flying boats, none of which was conceived or designed as a commercial air transport machine, in the problematic future. Incidentally, £5,000,000, which Capt. Balfour described as "not such dusty crumbs", is the equivalent of about one day's expenditure upon war machines "at the rich man's table". Compared with this, the U.S. Aeronautical Chamber of Commerce stated recently that at present one fifth of the multi-engined production of aeroplanes in that country is devoted to cargo aircraft and that it is expected to rise to one third in 1943. In Great Britain we have British Overseas Airways as the only operating company. In the United States there are seventeen air lines operating under the direction of the Government authorities, but retaining their own individualities and spheres of influence. We have not one firm producing or even designing civil transport machines, whereas in the United States three of the largest concerns are producing cargo-carrying planes, while a fourth is just going into production on the world's largest passenger-carrying aeroplane, an 80,000 lb. monoplane, the "Constellation".

Any country's work in connexion with a total war must obviously be a balance between the production of direct war requirements and the many subsidiaries necessary to maintain national life. Aeronautics, as one branch of this, must be governed by similar laws. We may not be able to get more than a pint out of Capt. Balfour's pint pot, but the dregs allotted to civil aviation from the British pint would appear to compare very unfavourably with the gill that American aviation is getting from their pot. It is obvious that there are many facets to a political situation of this kind, and that it needs extremely delicate handling, but to the ordinary man it must appear that, in the world of aeronautics, Great Britain has either blundered or allowed itself to be jockeyed, which is really the same thing, into a position of bearing a little more than a fair share of the burden.

HYDRO-ELECTRIC DEVELOPMENTS AND RECONSTRUCTION

THE report of the Cooper Committee on "Hydro-electric Development in Scotland" (see p. 187), the main recommendations of which have now been accepted by the Government and embodied in the Hydro-Electric Development (Scotland) Bill presented to Parliament, is a reconstruction paper which will require the early attention of whatever planning authority may be entrusted with the responsibilities recommended by the Barlow Commission or the Scott Committee. The report formulates a programme or policy without attempting to work out its practical implications to the last detail, but in doing so it promotes an admirable appreciation of the position of hydro-electric development in Scotland and supplement to the report on the Highlands and islands of Scotland issued by the Scottish Economic Committee in 1938.

The broad conclusion which emerges from the survey of existing electrical development is that the northern area of Scotland differs fundamentally from all the electricity areas of Great Britain and calls for an exceptional development policy, practice and outlook. In that area there is abundant water-power but no coal; there are no substantial industrial concentrations, and the population is very sparse and widely dispersed. Water-power as a source of energy has different economic and financial characteristics from those of coal-fired steam stations. That portion of the area popularly designated the Highlands has for long been a depressed area and will remain so unless vigorous and far-sighted remedial action is taken in hand without delay.

The Committee considers in some detail the two main theories of the future of the Northern Area, on which most of the proposals laid before it were based. One view, that any attempt to introduce modern industries and industrial methods is foredoomed to failure, since the Highlander cannot and should not be separated from his croft or his boat, however meagre the existence they are capable of yielding, is emphatically rejected. The other view, that the real test of the validity of any electrical project is the promise it holds of attracting new industries, proceeds upon the sound and only possible principle of treating the Northern Area as a whole, developing the more advanced districts as fully as possible, establishing new centres of development at selected sites throughout the area, and trusting to the gradual diffusion of prosperity from these focuses of development into the surrounding districts, including the crofting areas.

In regard to this view it should be remembered, as the Committee comments, that the provision of cheap and abundant electricity is only one, though a very important, factor in any programme directed towards the expansion of existing centres of industry and the creation of new ones. Secondly, the types of industry to which under the Committee's proposals the Northern Area could offer a very special inducement are those such as the electro-chemical and electro-metallurgical industries, which employ very large quantities of electricity and for which the abundant supply of very cheap electricity is indispensable. In regard to these industries, the Committee states that it is inconceivable that a country such as Great Britain, which is so deeply interested in every aspect of the metal industries, could refrain from active and intensive participation in their remarkable development in recent years, especially in view of the increasing importance which in modern technique is attached to the use of alloys. Moreover, it is considered beyond controversy that there is only one possible zone for siting such industries in Great Britain, and that is in northern Scotland in the vicinity of the larger hydro-electric sources. In particular, the district adjoining the Cromarty and Beauly Firths, the Lochalsh area, the upper reaches of Loch Tyne and the upper reaches of Loch Linnhe are specified. If the post-war industrial economy of Great Britain is based on deliberate planning on the lines adumbrated in the Barlow Report, the Committee considers there is an unanswerable case for delimiting this area for the purpose of such industries.

The Committee is confident as to the possibility of offering these industries such advantages in power supply as will provide a powerful incentive to their establishment in the Highlands. It attaches importance to the uncovenanted benefits which may be expected to result from the introduction into this area of a new spirit of enterprise and initiative and the provision at strategic points of modern centres of the most modern industry, on the basis of which the local population can erect a better and richer economic structure the advantages of which should permeate every branch of the life of the people. It sees no reason why these new centres should not be planned as a model of what an urban centre in a rural district ought to be, and it anticipates nothing but benefits to the district as a whole from the establishment of such industries as new markets for the produce of the adjoining districts, from the incidental provision of improved transport facilities and from the numerous conveniences and amenities which must inevitably follow.

Whether or not this confidence proves to be justified will largely depend on the machinery by which the programme proposed is executed. Fundamentally, some of the most important opposition due to earlier proposals such as the Glen Affric project derived from the well-founded belief that no private corporation could safely be entrusted with powers which might affect so powerfully the amenities and the development of a whole kingdom. This important objection is eliminated by the Cooper Committee's first proposal, to create a new public service corporation, the North Scotland Hydro-Electric Board, to which would be entrusted the responsibility for initiating and undertaking the development of all further generation of electricity in the Northern Area for public supply, and its transmission and supply in bulk to the existing undertakings, as well as of the generation, transmission and distribution in all areas outside the limits of existing undertakers.

This Board should have three primary objectives in its development programme: to attract to the Highlands through the offer of cheap and abundant power a share in the vital and expanding electro-chemical and electro-metallurgical industries; to develop such further power as may be required for the consumers of existing undertakers or for consumers in its own distribution area, the surplus being exported to the grid; and to develop on an experimental and demonstrational basis isolated schemes in isolated districts.

The recommendations of this report are closely linked with the measures recommended by the Barlow Commission and the Scott and Uthwatt Committees. Not merely the reconstruction of a depressed area and the development of important new industries are involved. These problems are interlocked with those of the utilization of land as well as of natural resources—forestry, agriculture, the preservation of natural flora and fauna as well as of our scenic heritage, the provision of opportunities for amenities and recreation for the whole nation, questions of town planning as well as of country planning—all require consideration in the development and execution of a plan which will worthily meet the opportunities.

The Cooper Committee makes plain its opinion that it is opposed to any system under which a person whose property or interests may be affected by the execution of a large public utility scheme is entitled not only to claim compensation for loss he may suffer but also to oppose the entire scheme on its merits. Its proposals for compulsory powers and more business-like and modern machinery in this matter of acquisition and compensation, and for the exemption of new schemes from rates either permanently or for a prolonged development period, however, have not been incorporated in the Bill now before Parliament. The suggested provision for the appointment of an Amenity Committee selected by the Secretary of State to advise the new Board in framing and executing proposals is unlikely to be satisfactory, however favourable the precedents cited, unless the proposals of the Scott Report are also implemented. The issues raised by the Cooper Report are wide and general as well as specific, and afford an outstanding opportunity for bold enterprise on the part of the Government.

MECHANISM OF THE ELECTRIC SPARK

The Mechanism of the Electric Spark
By Prof. Leonard B. Loeb and John M. Meek. Pp. xiii+188. (Stanford University, Calif.: Stanford University Press; London: Oxford University Press, 1941.) 3.50 dollars.

ALTHOUGH this interesting book bears the copyright date of 1941 at the Stanford Press, it has only recently been available in Great Britain, and will be regarded as an important supplement to Prof. Loeb's treatise "Fundamental Processes of Electrical Discharges in Gases" (1939). The reason for the appearance of a supplement to a very modern book of such comprehensiveness is to be found in the discovery by an Englishman, one of the authors, J. M. Meek, of a simple condition or criterion, which, applied to Prof. Loeb's qualitative streamer theory of spark discharge, converted an interesting speculation into a quantitative theory of great power. Dr. Meek (formerly of the University of Liverpool and the Research Department of the Metropolitan-Vickers Company) studied under Prof. Loeb with a Commonwealth Fund Fellowship, and there developed the conception and mathematical argument which has led to the satisfactory explanation and correlation of many inexplicable, apparently unrelated phenomena of the spark discharge.

Meek's work has appeared in several scientific journals, but Prof. Loeb has rendered very useful service in reviewing the former streamer theory afresh in the light of Meek's discovery, and the book will constitute a valuable addition to one's library of "J.J." and other works on gaseous discharges.

The book is dedicated to Townsend, "whose pioneer researches and theory laid the whole foundation for the study of the mechanism of the spark discharge": one wonders whether Prof. Loeb was hoping thereby to bring Saul also among the Prophets, for on p. 374 of the longer treatise he wrote: "Unfortunately Townsend and his school have been the last to concede the errors in reasoning". It must be admitted, however, in fairness to Townsend, that although the second Townsend coefficient β may have been an over-simplified explanation of the true facts, the facts have been so elusive to modern research that hundreds of papers have been written on the subject, and finality is not yet in sight.

The development of new theories of the spark discharge has its origin in three new experimental techniques: first and most important, in the development by Rogowski in Aachen of the high-voltage cathode-ray oscillograph, with which time-ags of spark formation could be measured; secondly, n the application of the Wilson cloud chamber to the study of sparks in the early stage of their formation; and thirdly, in the successful application by Schonland of the rotating camera to the study of the ightning discharge. The book gives full consideration to the first two, but in the writer's opinion does not do justice to the third. After all, we owe to Schonland and his co-workers, so long ago as 1933, the first direct evidence that a discharge occurs in at least wo main stages, the electron avalanche or leader troke of varying degree of complexity, followed by he main stroke developing in the opposite direction o the leader stroke. This dual process (expanded to a triple process by the authors) is the basic idea underlying modern theory.

The book is written in three chapters. The first deals with the Townsend theory and the difficulties evealed by research over the past ten years; the econd deals with the mechanism of the positive treamer, including the application of Meek's riterion; and the third gives quantitative examples f Meek's formula applied to breakdown in a uniform ield, in the field of a sphere gap and of coaxial ylinders, and the way breakdown is influenced by xternal ionization.

Chapter 1 is a condensation of Chapter 10 of Loeb's longer treatise. The Townsend second coefficient β was originally the number of new electrons created in a gas by a single positive ion in unit distance. At N.T.P. the velocity of such an ion in the breakdown field is $\cdot 10^5$ cm./sec., whereas the oscillograph shows breakdown to occur in 10^{-7} sec. for a 1 cm. gap, apart from any statistical time-lag. Thus positive ion ionization is ruled out in accounting for breakdown at such values of pressure and gap; moreover, abundant evidence exists that the positive ions cannot reach ionizing energy in the available field. Nor can any action at the cathode be invoked, especially for long gaps; the secondary processes must all occur in the gas and not at the electrodes. Here the cloud chamber and the Kerr electro-optical shutter camera provided the vital evidence; the initial phases of spark breakdown occur at the anode, anode streamers are found to develop towards the cathode, whereas cathode streamers would be expected from the Townsend mechanisms.

The anode streamer theory is fully developed in Chapter 2. The electron avalanche first develops from cathode to anode at a speed of about 10^7 cm./sec. This results in a large positive ion space charge mainly near the anode, which creates a field of magnitude comparable with that of the main field. Accompanying ionization, there is also produced a large number of excited atoms and molecules, which in 10^{-8} sec. are emitting light of very short wave-length readily absorbed in the surrounding gas and copiously liberating photo-electrons. Those liberated near the positive ion space charge of the initial avalanche will be accelerated in the combined main and space-charge fields, and the positive ions left behind will extend the space charge towards the cathode. Thus the space-charge volume develops towards the cathode as a self-propagating streamer having a velocity probably in excess of 10^7 cm./sec. When this reaches the cathode, there is a conducting filament bridging the gap; and provided the potential is still maintained, current builds up from the cathode to the anode as a highly conducting spark or arc—the 'main stroke' of the lightning terminology. Meek suggested that the self-propagating streamer only developed when the field due to the space charge created by the avalanche reached a magnitude equal to that of the main field. Setting up the equation for this condition, Meek was able to calculate the main field strength for breakdown between parallel planes, and obtained almost exactly the experimental value. Furthermore, his formula gave good agreement with Paschen's law down to 1/8th atmosphere for a 1 cm. gap, below which it is known that time lags increase considerably above values obtaining at N.T.P. We see at once why with over-voltages applied to gaps the positive ion streamer will start even before the avalanche has reached the anode, and thus we get an explanation of the occurrence of mid-gap streamers and reduction in the formative time-lags. Branching of the positive streamer discharge is to be expected, since the incoming avalanches created photo-electrically may come from any direction roughly between the space charge volume and the cathode.

With long gaps at N.T.P., Loeb suggests that the electron avalanche cannot cross the gap in one process; after a certain stage, its progress is arrested by the field of the space charge behind it, and a positive streamer forms and progresses back to the cathode. This results in a reduction of the space-charge field and a virtual extension of the cathode, so that the electron avalanche/retrograde positive streamer process continues in steps across the gap. This is virtually the mechanism of the lightning flash from the negative cloud, and now the succession of retrograde positive streamers becomes Schonland's 'leader stroke': and the 'main stroke', instead of proceeding from cathode to anode, proceeds from ground (positive) to cloud (negative). The discharge mechanism can start also from the anode at suitable field strengths. Here electron avalanches drawn into the anode leave positive space charges which virtually extend the anode towards the cathode. As the space charge here augments the main field, sparkover voltages for large gaps are lower for positive than for negative potentials. This explanation is in line with the explanations already offered for the different appearances of the rotating camera photographs of long sparks. Both authors present theories for the cause of stepping of the lightning leader stroke. Meek suggests this is due to ageing by recombination followed by rejuvenation. Loeb suggests it is due to replenishment of lost electrons in the avalanche process.

Chapter 3 is a valuable exposition of the many spark phenomena correlated by Meek's theory. A most important feature of the calculation is the value to be given to the ratio of main field to space-charge field for breakdown to ensue. A change in this ratio of 10 : 1 only alters the calculated breakdown voltage for a 1 cm. gap by 2 per cent, and the decision as to choice of ratio was taken on the 1 cm. gap breakdown voltage. This arbitrary choice is already the subject of criticism, and further development of spark theory will almost certainly depend on the physical significance of this ratio. The chapter has been extended somewhat in a recent paper by Meek (*J. Inst. Elect. Eng.*, **89**, 335, Aug. 1942), to which interested readers are referred.

The book is well written and most enjoyable. It is unfortunate that errors were not eliminated from the text, but that was due to the separation of the authors and their preoccupation with other urgent problems. T. E. ALLIBONE.

DISCUSSING HEREDITY

Cytology, Genetics and Evolution

By M. Demerec, Charles W. Metz, Franz Schrader, Albert F. Blakeslee, Th. Dobzhansky, Clarence E. McClung, Herbert S. Jennings, William F. Diller, T. M. Sonneborn, Leon Churney, William R. Duryee, Paul S. Henshaw. (University of Pennsylvania: Bicentennial Conference.) Pp. v+168. (Philadelphia: University of Pennsylvania Press; London: Oxford University Press, 1941.) 12*s*. net.

THE second centenary of "The New Building" was celebrated, in more prosperous circumstances than the first, by holding a conference at Philadelphia, during September 15–21, 1940. A part of the proceedings of this conference seems to be included in the present volume. The editor's name is not mentioned; indeed, there is no introduction or preface. In default of any explanation the reviewer may perhaps attempt to fill the gap and place the papers in relationship.

To begin with, the last paper should properly come first. Henshaw's discussion of "Radiation and the Cell Nucleus" is a useful introduction to the physical side of the subject. Reference to the extensive recent American work on the biological side of the mechanism of X-ray breakage of chromosomes is, however, omitted. Jumping this gap we come to two articles on the physico-chemical structure of the cell and nucleus by Churney and Duryee. Duryee describes microdissection and other experiments with the amphibian nucleus. Most striking is his study of the formation of nucleoli and his method of expelling the nucleolus from the nucleus by changing the *p*H of the medium. Some misconceptions could perhaps have been avoided by comparison with fixed and stained preparations.

Third should be taken two articles by Metz and Schrader on chromosome structure. Schrader has evidence that a fusion of heterochromatin is perhaps the basis of the second division pairing of sex chromosomes in the Heteroptera. He does not, however, recognize the relationship of such fusion with nucleolar fusion and its distinctness from the specific prophase association of homologous genes. The situation becomes clear only when plants and animals are considered together.

The next step is shown by Demerec's article on the "Nature of the Gene", which explains the evidence for the chromomere-gene equation. It also explains the connexion between observed breaks and exchanges in salivary gland chromosomes of Drosophila, and the physiological expression of genes. The fifth step is contained in Blakeslee's and Dobzhansky's accounts of the structural changes in chromosomes found to distinguish natural races in Datura and Drosophila. The situation is indeed widely different in the plant and the animal. But it is different, not because they are plants and animals, but because geographical isolation precedes differentiation in Datura, while it may or may not follow it in Drosophila. In the one, therefore, the segmental interchanges occur as accidents; in the other the segmental inversions occur as the condition of isolation—isolation first of segments of chromosomes, and later of individuals and races.

Next we arrive at a disconnected group of papers on Rhizopods and on the ciliated Protozoa. Sonneborn deals with the anomalous genetics, Diller with the anomalous cytology, of the relatives of Paramecium. It has to be admitted that the genetics cannot be satisfactorily considered until the cytological situation becomes clearer. Diller's comparative account, however, stands for a great advance, particularly in regard to the understanding of polyploidy and autogamy. A still further advance will come when the newer methods of recognizing nucleolar and nuclear constituents are applied to the group.

Finally comes an article by McClung on the "Evolution of the Germplasm". McClung presents an abstract of the problems that confronted Lamarck, Darwin and Weismann (whose names he does not mention), together with a mixture of the solutions they offered. The account is mystical and even in places meaningless. Many will regret that, while McClung's initial discovery of the sex-chromosomes has led his disciples forwards, it has apparently led him backwards to such a point as this.

We can gather that at the time these papers were written their authors did not know of the collection that was to be made of them, for only one cross-reference occurs in the book. This is a subject, or a group of subjects, in which above all cross-reference is needed at the present moment, and a symposium should provide precisely the means to this end. A year later the Cold Spring Harbor Symposium on Chromosomes and Genes (see NATURE, **149**, 242; 1942) achieved just this object and in doing so will prove itself an important milestone in the advance of biology. The present series of papers may be taken as an easy introduction to the larger work.

C. D. DARLINGTON.

SIR JOSEPH BANKS, P.C., K.C.B., F.R.S. (1743–1820)

By JOHN D. GRIFFITH DAVIES

"THE works which this man leaves behind him occupy a few pages only: their importance is not greatly superior to their extent; and yet his name will shine out with lustre in the history of the sciences."

With those words Cuvier opened his *eulogium* on Banks at a meeting of the Académie Royale des Sciences at Paris on April 2, 1821. On such an occasion extravagant language is to be expected; but Cuvier spoke no more than the simple truth when he placed the Academy's former foreign member high on the roll of those who have made history in science; and the rightness of his judgment has not been varied in the passing of the years.

Whether Banks is to be accounted a man of science, as this term is now understood, is a debatable point. He described himself as a *botanizer*—a status now to be regarded as inferior to that of botanist. Nevertheless, there are some present-day botanists who are convinced that, when judged against the background of botanical science in his times, the botanizer Banks can justly be acclaimed a competent botanist.

Personal fortune undoubtedly made it easy for him to indulge his life-long interest in natural history. Born in Argyle Street, London, two hundred years ago this month, the son of a wealthy Lincolnshire landowner, he inherited an estate worth £6,000 a year when he came of age in 1764: a princely income in those days when money bought more than it does now, and when the State made far fewer incursions into a man's pocket. Harrow and Eton (he went to both schools), and later the "House" at Oxford, brought him no academic distinctions. Indeed, he had little liking for the customary classical studies. In 1807 he confessed to a correspondent: "I am scarce able to write my own language with correctness, and never presumed to attempt elegant composition, either in verse or in prose, in that or any other language". For that reason, he went on to say, it was improper for him to agree to become a member of the projected Belles Lettres Society: "It is fitting, therefore, that I continue to confine myself, as I have hitherto done, to the dry pursuits of Natural History".

Natural history was his absorbing interest both as a schoolboy and undergraduate. Though Oxford had a chair of botany, its occupant in Banks's time was Humphrey Sibthorpe, of whom it is recorded that he delivered but one lecture on his subject in thirty-five years. It was characteristic of Banks, always the man of action, that he should ask Sibthorpe's permission to import into Oxford the self-educated young Cambridge man, Israel Lyons, recommended to him by John Martyn, professor of botany in that University; and it was under Lyons's direction, and with the enthusiastic support of Banks and his friends, that there was revived in Oxford a lively interest in botanical studies.

Even as a young man Banks must have possessed an attractive personality. He made friends easily, even among men older than himself; and, when shortly after coming down from Oxford he acquired a town house in New Burlington Street, he entertained them with that hospitality which was later to make him famous when he removed to Soho Square. He was elected into the fellowship of the Royal Society in May 1766: among his sponsors were James West, later to be president of the Society, Charles Morton, principal librarian of the British Museum, and William Watson, distinguished both as physician and botanist.

A love of adventure was in Banks's blood. In 1766 he sailed in the fishery protection vessel, the *Niger*, to Newfoundland and Labrador. He at once proved himself to be a good sailor (later he was accused by his enemies of preferring the company of sailormen), and also a skilful collector of botanical specimens, though some of his collection was destroyed by heavy seas on the homeward journey. Two years later he sailed with Lieutenant Cook in the *Endeavour* to Otaheite to observe the transit of Venus, and thus took part in one of the memorable voyages in British naval and exploratory history. When the Council of the Royal Society petitioned the Admiralty for permission for Banks to accompany the expedition, they described him as "a gentleman of large fortune, who is well versed in Natural History", and declared that his going would be "for the advancement of useful knowledge". No doubt the petition was the more favourably received because one of Banks's Lincolnshire neighbours, Sandwich, who was particularly identified with Jemmy Twitcher of Gay's *Beggar's Opera*, was a Minister of State, and had great influence at the Admiralty.

Banks told the story of that adventure in his "Journal": read alongside the log of the *Endeavour* it gives an insight into the character of the man. He is filled with youthful enthusiasm; nothing escapes his notice. Whenever there is opportunity of shore excursions Banks and Solander, the professional botanist, are hard at work collecting specimens or observing natural phenomena. All is recorded faithfully and with commendable modesty, particularly when it is recognized that Cook looked upon him as a tower of strength in adversity. He handled the natives easily and with understanding. When an instrument is stolen it is Banks whom Cook dispatches to effect its return. Great was the disappointment among the natives when on later voyages Cook had to confess that Banks was no longer his companion. One is tempted to think that the great navigator would not have met his tragic end had Banks, in whom the natives placed such complete confidence, been at hand.

Here is not the place fully to examine the reasons why Banks did not accompany Cook on the latter's second voyage. One thing is certain: it was not because of any personal animosity between the two men. Whatever Banks's enemies said (and they said a great deal), the vessel, the *Resolution*, provided by the Admiralty did not permit of the elaborate structural alterations necessary for the accommodation of his suite. Cook, a competent sailor, bluntly said that he would not risk taking her to sea with a superstructure such as was contemplated; his superiors knew that he was right. So Banks and his party consoled themselves with a botanical expedition to Iceland, an account of which is to be found in Troil's "Letters on Iceland" (1781). This was the beginning of a life-long interest in Icelandic affairs. Not only did he serve the Icelanders by persuading the Admiralty to release their ships, held in British ports when the Danes joined Napoleon, but also he was even sounded by the Government with the view of initiating a move in Iceland to break with Denmark and place the island under the protection of Great Britain.

Banks's reputation was now firmly established, and on November 30, 1778, he was elected president of the Royal Society. The election was not universally popular among the fellows. He was young, and, so the mathematicians averred, wholly unfitted to direct the affairs "of that society in which philosophy once reigned, and Newton presided as her minister". The storm burst about him in 1783–84. He had charged Dr. Charles Hutton, the secretary for foreign correspondence, with neglect of duty. When the latter resigned, his mathematical friends, led by Dr. Samuel Horsley, a former secretary of the Society, rallied round him; and strove in open debate and in scurrilous pamphlets to oust Banks from the presidency. The details of this unfortunate dispute are too complicated fairly to be stated in a short article: suffice it to say that in the end Banks triumphed. Whether or not he was overbearing in his treatment of his colleagues, and ruthless in the conduct of his defence when assailed by those who would not yield to his will, cannot easily be decided. Certainly Banks was a masterful man; he was notoriously impatient of slipshod methods; he wanted action; he had his following, those fellows who were admitted to his brilliant receptions in Soho Square. But whatever may have been his faults, he was intensely loyal to the Royal Society, and was resolved that its fortunes should flourish under his direction. If he introduced into the fellowship (as his detractors said he did) men who had no claim to be regarded as men of science, he did so because he sincerely believed that the patronage of such men was essential for the improvement of natural knowledge; and he did not scruple to use their influence to obtain from Government the means to finance scientific research.

Organized science in Britain had no reason to repent of its choice of leader. Herschel's discovery of Uranus and his plans for the making of a large reflecting telescope, the planning of a geodetic survey of the British Isles, the Cavendish-Watt controversy over the composition of water, Young's undulatory theory of light, the need for proving the standards of weights and measures, the possibility of navigation through the North-West Passage—these were only some of the interests which agitated the scientific world during Banks's long presidency of the Royal Society. To assess his part in them is an unenviable task. As president of the Royal Society he was bound to bask in the reflected glory of the achievements of its fellows. Of chemistry, physics and astronomy he knew little (and he would have been the first to admit it); but he considered it his duty to assist all who were grappling with scientific problems; and there was no length to which he would not go in order to obtain official recognition of scientific work. Having the ear of the king, George III, he was able to lighten the privy purse of funds for the geodetic survey and the cost of making Herschel's telescope; with powerful friends at the Admiralty he could easily interest the sailors in the Society's schemes for the exploration of the North-West Passage. That the Government again came to appreciate the value of science is clearly demonstrated by the decision to provide the Royal Society with free quarters in Somerset House (1778): the improvement of that accommodation was incidentally one of Banks's first presidential acts.

Much could be written of Banks's personal relations with the king. George III was "quite a piece of a farmer": he was keenly interested in horticulture and the raising of cattle. Suspicious of the professional politicians, who not only thwarted him at every turn but also ridiculed him in their clubs, it was a relief to enjoy the friendship of a man like Banks, who stood aloof from the political arena. Together they would talk over the best methods of growing wool, even exchanging rams and ewes from their respective flocks; together they would plan the lay-out of the royal gardens at Kew, so dear to the king's heart since they had been the passion of his unhappy mother. During George III's reign nearly seven thousand exotic plants were introduced into England, and it is estimated that by far the greater number of these came to Kew through Banks's collectors.

It was impossible to enjoy the royal favour without incurring the ridicule of George III's enemies. Peter Pindar's venomous shafts were frequently aimed at Banks. He was accused of trying to amuse the Royal Society with frogs, flies and grasshoppers; he was said to have kept its fellows awake with loud raps of the presidential hammer; and, worse still, he sometimes swore in their august assemblies! Gillray's famous caricature is well known: *The Great South Sea Caterpillar Transformed into a Bath Butterfly*. "This insect," states the legend, "first crawled into notice from among the weeds and mud of the South Seas, and, being afterwards placed in a warm situation by the Royal Society, was changed by the heat of the sun into its present form. It is noticed and valued solely on account of the powerful red which enriches its body and the shining spot on its breast; a distinction which never fails to render caterpillars valuable." The king's enemies laughed heartily at Gillray's work—and, incidentally, so did Banks!

The caricaturist had, however, laid bare one of Banks's weaknesses. There is no doubt that he was inordinately proud of the K.C.B. which the king bestowed upon him in 1795; nor was he less proud of his admission to the Privy Council two years later. At all functions, whether official or semi-official, he appeared in court dress—a splendid figure of a man with the red sash across his body and the order conspicuously displayed on his breast. In that garb he presided over the Council and ordinary meetings of the Royal Society, sitting in the chair (his own gift) which is still used by the president.

Another of Banks's weaknesses was his dislike of all attempts to found new scientific societies. He believed that they must inevitably weaken the Royal Society; and that was not to be tolerated. If they were content to remain associations of scientific men, dependent upon the Royal Society, all well and good: otherwise they were to be opposed with all the powers at his command. Yet he helped to found the Linnean Society in 1788, and was its first president; he was also associated with the founding of the Royal Horticultural Society; it was in Banks's house in Soho Square that the famous meeting was held which resulted in the founding of the Royal Institution. On the other hand, he withdrew from the Geological Society when that body refused to become a dependency of the Royal Society; and, at the close of his life, he resisted most resolutely the move to found the Royal Astronomical Society, even persuading the Duke of Somerset, designated as first president, to refuse to accept office.

After his voyage with Cook, when both New Zealand and Australia were visited, Banks was looked upon by king and ministers as *the* authority on Australasian affairs; and there is positive evidence that he refused high political office in order to leave himself free to watch over the destinies of the young colony, in whose future he had unbounded faith. When Europe was distracted by the Napoleonic wars he could write to Hunter, the governor of New South Wales: "I see the future prospect of empires and dominions which now cannot be disappointed. Who knows but that England may revive in New South Wales when it is sunk in Europe." To those who were entrusted with the government of the newly established colony his advice and encouragement were invaluable. Phillip, Hunter, King and Bligh, fighting manfully to give New South Wales an orderly government and thwarted by the professional soldiers who augmented their meagre pay by trafficking in rum, poured out their troubles to him; he reciprocated by doing everything in his power to smooth over their difficulties. In Bligh, that most maligned of men, he never lost confidence. Banks knew him for an expert sailorman, a wise and just governor; he could appreciate, perhaps better than Bligh's traducers, the courage which had been required of the latter when he navigated the loyal men of the *Bounty* through the Timor Sea. And all the time, intermingled with his words of counsel and encouragement, were requests for specimens of plants and any information which might be of value to men of science. It was not to be a one-way traffic in plants. "My business," said Banks to Hunter, is to be "the encourager of the transport of plants from one country to another." The young colony needed a supply of "useful plants"—hops, for example, were to be shipped to New South Wales in the hope that beer would diminish the consumption of rum; and it was Banks who tried to ensure that the colonists' needs were supplied. There were, of course, disappointments. Consignments of specimens were sometimes lost at sea, on homeward and outward voyages, and official support was not always forthcoming in London; but Banks never lost heart; and he could boast to Hunter that "we shall before it is long see her [Great Britain's] ministers made sensible of its [New South Wales's] real value". It is not to be wondered that our kinsmen in Australia look upon Banks as the 'godfather' of their country, and have zealously collected a great wealth of his papers.

Banks was unquestionably a great European. In London his name was a household word; even the humblest citizen knew of the "great Sir Joseph" who lived in Soho Square. Abroad, men of science looked upon him almost as the protector of all scientific effort, especially when the Napoleonic wars interrupted the free exchange of ideas between England and the Continent. Cuvier's tribute to his brave, and successful, endeavours to raise science high above the quarrels of nations is not an unfitting conclusion to this memoir. "During the long period of two and twenty years," said Cuvier, "in which war extended its ravages to every part of the two worlds, the name of Banks was in all places a palladium to such of our countrymen as devoted themselves to useful researches. If their collections were seized, they had only to address themselves to him to ensure their restoration; if their persons were detained, the time occupied in acquainting him with the fact was the only delay which was interposed between them and liberty. When the seas were closed in upon us on all sides, his voice opened a passage to our scientific expeditions. Geography and natural history are indebted to his solicitude for the preservation of their most valuable labours:—but for him our public collections might now, and perhaps for ever, be deprived of the riches which adorn them."

Banks died at his house at Spring Grove, Isleworth, on June 19, 1820: he was buried, as he wished, with neither pomp nor ceremony, in the graveyard of Heston parish church.

PRODUCTION GENETICS IN SWEDEN

By Dr. C. D. DARLINGTON, F.R.S.

NATIONS often have to rely for their independence on the independence of their food supply. This principle is as well understood in Sweden as in Great Britain, and for similar reasons. Since the War of 1914–18, however, Sweden's position has been greatly improved. The annual yields of wheat and sugar-beet have been increased to the point at which the country is just self-supporting. The most important factor in this increase has been the improvement in the farmer's seed by plant breeding; indeed, one quarter of the wheat and nearly one half of the sugar harvest may be put down to the use of improved seed.

Sweden might seem to be a particularly grateful field for the plant breeder because, like Canada and the U.S.S.R., it lies on the northward margin of cultivation; any slight change in hardiness or growth-rate or light-response which pushes the limit of growth slightly farther north therefore throws open a vast new territory to cultivation. On the other hand, as we shall see, the severity of the Swedish climate does not allow the plant breeder to win his victories without a struggle. What these victories amount to I have recently had the privilege of seeing.

The foundation of Swedish success in plant breeding lies in the small village of Svalöv in Skåne, the richest and southernmost province of Sweden. At this centre we find three partners working together. The youngest of the three is the Institute of Genetics of the University of Lund, some twenty miles from Svalöv. This is a department for teaching and research. It was established for Prof. Nilsson Ehle in 1927 and is now directed by Prof. Müntzing. The second partner is the Svalöv Plant Breeding Institute, formerly directed by Nilsson Ehle and now by Prof. Akerman. This Institute is immediately responsible for the production of new varieties, but is, at the same time, concerned with long-term research and houses a part of the Institute of Genetics. The third partner is the Swedish Seed Company, which has the monopoly of maintaining the stocks and selling the seed of the Svalöv varieties and controls each step between selection and marketing. Without this monopoly it was realized that the maintenance of scientific standards could not be guaranteed. The triple organization, now occupying about three thousand acres, arose at first from a farmers' union, but it is now supported and partly controlled by the Government.

This system has developed during the last fifty years and has grown as the field of possible activity has extended and the numbers of crops that have seemed worth while improving have increased. It began with cereal breeding and with the union, on one hand, of the new genetic analysis of quantitative inheritance in terms of cumulative factors by Nilsson Ehle and, on the other hand, of the practical understanding of the plant breeding problem by the first director, Hjalmar Nilsson. This union we now see bearing fruit equally in the practical and the theoretical field.

The first development of the Svalöv organization was the formation of subsidiary stations to meet the local needs of the main climatic regions of Sweden. For example, the Undrom station deals mainly with herbage plants but also with potatoes, while in the far north (latitude 66°) the Luleå Station produces new types of barley and oats. The station at Ultuna, near Uppsala, is of the first importance, and Ultuna has recently been made the site of a centralized agricultural college for the whole of Sweden, a choice which arises not from its central geographical position but from its marginal agricultural position. The new problems and the most difficult ones are on this northern margin. Here under Prof. Turesson some of the most important work is concerned with genetic acclimatization.

The second development has been the formation of specialized stations for particular crops. For example, at the beginning of the War the shortage of textiles brought home to the authorities the importance of fibres, and the flax research was transferred to a new laboratory under Dr. Granhall at Månsabo, near Svalöv. Just as the wheat-breeding department has its complete milling and baking installation, and the sugar-beet laboratory its complete extraction and assaying equipment, so for flax a complete retting installation has been set up, together with special apparatus for retting small selection samples. The industrial equipment necessary as a foundation for plant breeding is never spared.

Sweden's abundance of forests could not long be overlooked where the possibilities of plant breeding were considered. In 1936 a new research station was established by a Society for Breeding Forest Trees. It lies in fifty acres of experimental ground at Ekebo, near Svalöv. An expedition led by Prof. Turesson in 1938 provided a valuable collection of forest-tree seed from North America as a foundation for the work of acclimatization and hybridization.

Under Dr. Nils Sylvén, this work has already gone far. Four regional branch stations have been set up. A genetic survey of Swedish forest trees has revealed a prodigious range of variation in usefulness (just as one sees in Great Britain) both within communities and between them. The ecotype principle is singularly well demonstrated in the differences within species in regard to long- and short-day habit, for when transplanted to a different latitude the unadapted individual is obviously and entirely useless.

A special form of selection has resulted from the discovery of triploid aspens with as much as twice the growth-rates of the neighbouring diploid trees. Many of the later examples have been discovered by farmers and foresters who had been told to look out for them. These valuable trees are being propagated for their own localities, and tetraploids have also been obtained from them. The discovery of these forms has led to the systematic use of colchicine, which has been successful in producing tetraploids in Sequoia, Larix, Pinus and Abies. Artificial lighting, refrigeration and special grafting methods are being used to shorten the work of breeding and propagating.

Naturally, fruit being something of a luxury in Sweden, fruit breeding has been the last problem to be tackled, but two factors have lately directed attention to its importance. First, the damage done to the orchards in Sweden—only less serious than in Finland—by the three severest winters ever recorded, shows the necessity of producing native fruits selected for the Swedish climate. Secondly, the value of vitamin C in a country cut off from southern fruits is obvious. Valuable work has indeed been done in surveying the native rose population for its ascorbic acid content, and maintenance of vitamin content is regarded as an important object of potato breeding.

The origin of the fruit work at Svalöv is typical of the confident purpose of Swedish plant breeding. Triploid apples are in general not only larger but also later keeping and richer in vitamin content than diploids. In order to produce them regularly it was necessary to have tetraploids. Half a million natural seeds of the best triploid varieties were sown. All of them, of course, would be crosses with cultivated diploids. From them twenty-eight tetraploid seedlings—recognized by their larger stipules—have been obtained in the last five years. With this initial endowment the new fruit-breeding stations which are being set up at Alnarp and Balsgård will have a promising foundation.

Instead of relying on such chance origins, however, the plant breeder can now produce polyploids at will by the use of twin seedlings, collected by the seed-testing stations, by heat, and especially by colchicine treatment. These methods have been taken up with enthusiasm and success in Sweden. Tetraploid forms of clovers, lucerne, herbage grasses, barley, rye, flax, potatoes, sugar-beet and other crops have been produced and are being tested; some have already been proved of practical use. Octoploid wheat-rye hybrids, first raised in the U.S.S.R., are now regularly produced by the doubling of crosses between suitable parents for different conditions and purposes. The selection of their derivatives has made available a large range of forms of good baking quality and high yield and hardiness. In fact, a new grain crop of special value for Sweden and other countries has been created, the first such invention for three thousand years.

Research in Prof. Müntzing's department has indicated the mode of action of colchicine in arresting cell-division and doubling the chromosomes. It has also shown the nature of the anomalous systems of reproduction in herbage grasses, particularly Poa, where either meiosis, or fertilization, or both, may be omitted, with the production of new forms; where secondary polyploids breed true; and where pseudogamy depends on the fertilization of the endosperm nucleus alone. Dr. Å. Gustafsson at Svalöv has succeeded in unravelling another anomalous situation in the Canina roses by crosses which have produced new types of reproduction. These investigations are revealing principles of permanent importance in plant breeding. Similarly, the study of the nucleic acid cycles of crop plants which is now being linked up with Caspersson's cell physiology in Stockholm will lay the foundation of new methods of plant breeding.

Geneticists have long had misgivings about the value of X-ray mutations in plant breeding. Gustafsson, however, has made extensive trials and selections of the progeny of X-rayed barley in the third and fourth generations. From the variety Golden Barley he has obtained selections with as much as 10 per cent increase of yield. Whether or not these forms are directly utilizable it is clear that they provide the material of future improvements by recombination. The use of the X-ray method is therefore being extended.

Animal breeding is generally slower than plant breeding and its advantages take longer to prove. Moreover, in Sweden, as in Great Britain, superstition is deeply embedded in the minds of the breeders, although it is not, as here, incorporated in official handbooks. The Swedish Animal Breeding Institute with its well-equipped laboratories is situated on an extensive stock farm at Wiad, near Stockholm. Here Prof. Bonnier has set about reducing the difficulties of the problem by applying the latest technical devices. Artificial insemination is used to make rapid progeny tests of young bulls so that the same bulls, and not their progeny, can be bred for stock improvement. Special tests, again with artificial insemination, have been made for the choice of parents in hybrid-vigour crosses of poultry. New breeding systems have been established for preserving standardized and uniformly cross-bred stocks of poultry by using mixed sperm. These methods are influenced by the hybrid-vigour technique applied with pre-eminent success by Rasmusson to sugar-beet, and to maize in the United States. Finally, the possibilities of physiological experiment with monozygous twins have been exploited by a national collection of such twins in cattle. This deserves special consideration.

One half per cent of all cattle births are twin heifers. To determine which of these are monozygous a preliminary questionnaire is put to the farmer. Those passing this test are bought and submitted to Kronacher's nose-print and hair-whorl tests. Of the first 215 applications seven pairs fulfilled the conditions of identity. In this way nearly a hundred pairs of monozygous twins have now been collected at Wiad from all over Sweden. With these it has been possible to set up physiological experiments covering the practical problems of nutrition and maintenance. From these experiments the genetical variable has been removed. Already questions have been answered with a certainty which could not otherwise have been attained at fifty times the cost. Further, the answers are of importance far beyond the field of husbandry, especially, of course, in medicine.

The lessons of practical breeding—or production genetics as we may call it—in Sweden have their lessons for Great Britain with its vast responsibilities for farm, forest and fruit crop production at home and overseas. The results depend on a policy consisting of the following coherent elements:

(1) Genetics is taught in the universities;

(2) Posts are available in genetic research for the ablest university students;

(3) Men are therefore available to teach in the universities who have done research in this subject and thus actually understand how it works.

This is a train of events which a little thought shows is indeed necessary for the healthy development of any science. But this is only one side. The university departments carry on their work in close collaboration with the applied departments of agriculture and medicine and with the research stations. This leads to an integration of subjects and methods. It leads to a realization of the use of statistical, chemical and cytological techniques in genetics, and of genetical techniques in physiology. Finally, the research stations benefit by a direct flow of ideas and of trained personnel from the universities, and themselves in consequence conduct long-term or 'pure' research of value.

This integration is responsible for what may be described as the engineering method of Swedish plant and animal breeding: a bold combination of scientific basis and long-term planning, with a practical purpose and with practical collaboration. The practical collaboration depends again on the Swedish farmer or medical man himself understanding, as a result of education and propaganda, what profit can be gained by using the latest scientific methods. Such a system and such results do not arise by individual effort or accidental whim. They depend upon an instructed national policy.

ADVANCES OF CHEMICAL KINETICS IN THE SOVIET UNION

By NIKOLAI SEMENOV

Member of the Academy of Sciences of the U.S.S.R.

[The school of N. Semenov is well known to physical chemists throughout the world. Its outstanding contribution has been the application of the theory of branching reaction chains to problems of combustion and explosion. In 1935 Semenov himself published a standard treatise on "Chemical Kinetics and Chain Reactions". His ideas have provided a comparatively easy way through many complex and mysterious phenomena. The following article describes how the theoretical and practical work of his school has developed.—Editors, NATURE.]

UP to the twenties of the present century, 'chemical kinetics', or the science of the regularities underlying the course of chemical transformations, was largely in obscurity. But from this time onwards it becomes one of the predominating trends of physico-chemical studies.

As regards homogeneous chemical processes, the concepts of van't Hoff and Arrhenius were to undergo considerable modification. The idea was advanced that the reactions proceed through a number of stages, or intermediate products such as free atoms and radicals or particles excited by electrons. The work of Bodenstein, Haber, Christiansen, Polanyi, Lind, Bäckström and others during 1913–28, especially experiments on the formation of hydrogen chloride and bromide, was the first to suggest the new ideas and the methods of computing the velocities of these reactions. It is in connexion with these studies that the first idea of chain reactions was inaugurated.

It will, however, be noted that no general significance was attached to chain reactions up to 1927. They were considered as confined to very few individual cases.

The situation changed appreciably in 1927, after the publication of the first papers from the Institute of Chemical Physics of the U.S.S.R., and, soon after, of quite independent studies by Hinshelwood and his school in England. It was shown that chain reactions represent a large group of chemical transformations. A theory of chain reactions was developed, new and stimulating ideas were introduced regarding branching of chains and their being cut off on the walls of the vessel: the principal laws of these reactions were deduced and verified experimentally.

From 1928 onwards, these new studies in the domain of chain reactions were discussed at physico-chemical congresses and conferences throughout the world, and they have given rise to numerous experimental studies. During 1934–35, Semenov's monograph "Chain Reactions" was published in Russian and in English. This book reviews all the evidence bearing on chain reactions and gives an exhaustive and systematic discussion of the theory. In all monographs and books on chemical kinetics, the doctrine of chain reactions occupies a significant place. During 1941–42 an article by Semenov was prepared for press on the general theory of complex reactions, in which a strict mathematical treatment of the theory of chain reactions was presented in a new general form.

The theory of chain reactions postulates that in the course of chemical transformations there appear extremely unstable energy-rich intermediate products (atoms, radicals, unstable peroxides and other labile products). The urgent necessity then arose of determining the nature of these products. The lack of suitable methods still rendered this task almost impossible, and this most important problem could be solved only in one or two cases.

In 1937, the problem was taken up in the laboratory of Prof. Kondratiev (Institute of Chemical Physics). It was shown that, in rarefied flames of hydrogen, free hydroxyl is formed in very great quantities (up to 0·1 per cent of the initial hydrogen) as an intermediate product of oxidation of hydrogen. The amount of hydroxyl is hundreds of thousands times greater than that corresponding to the temperature of the experiment. Kondratiev determined the hydroxyl by a specially devised absorption spectrum method. He also detected CS and SO radicals in the oxidation of carbon disulphide.

Of great interest also is the work of N. Emanuel (1939–42), in which large quantities of SO were shown to appear in the course of carbon disulphide oxidation, and the role of this active intermediate product was established.

A specially detailed study was made of the kinetics of the oxidation of hydrogen and of various hydrocarbons. Naboldin's work (1932–42) showed that the theory of chain reactions accounts for the whole peculiar course of the reactions not only qualitatively but also quantitatively. Concurrently with studies in other countries, the intermediate products of hydrocarbon oxidation were explored in detail, since owing to their relative stability they can be detected with less difficulty. By 'freezing' the reactions at a given stage, Prof. Neuman detected and determined quantitatively by various methods (in particular, polarographic methods) different intermediate products (peroxides, aldehydes, etc.) appearing in the course of oxidation of hydrocarbons.

The phenomenon of cold flames of hydrocarbons, which is very interesting and significant in connexion with detonation in the petrol engine, was subjected to an especially detailed analysis by Prof. Neuman and his collaborators at this Institute (concurrently with the English school of Bone).

Another important branch of chemical kinetics deals with the theory of flame, where chain reactions, as shown in this Institute, mostly play a significant part.

In the twenties of the present century, no satisfactory theory of burning existed—a direct result of the backwardness of chemical kinetics. The work of the Institute of Chemical Physics introduced into the theory the major element, namely, the chemical kinetics of the reactions. This resulted in the establishment of the fundamentals of a theory which accounts for all the principal phenomena associated with burning in gaseous systems. Most of the results obtained are discussed in Semenov's papers (1940–41) under the general title "Theory of Burning", and in articles by Prof. Seldovich.

In 1927 Semenov formulated the now universally acknowledged theory of thermal explosion. At the same time he defined another type of inflammation, namely, the chain type. It was shown experimentally by Sagulin and others how to differentiate between the two types of explosion.

In 1931 the theory of the 'degenerate' explosion was developed, and also the theory of inhibition of explosion applicable to those cases where slow development of the branching chains (chain 'degenerate' explosion) results in an acceleration of the reaction to the point of thermal ignition. This accounts for the induction period, which sometimes lasts scores of minutes before explosion sets in. These phenomena have been studied in detail in the U.S.S.R. and elsewhere, the results being in full conformity with the theory. Degenerate explosions occur, in particular, in the oxidation of hydrocarbons. The great significance of the induction phenomenon and of the laws studied at the Institute of Chemical Physics on the theory of detonation in the internal combustion engine was soon realized, accounting for the interest aroused by these studies among engineers. All modern theories of detonation in internal combustion engines stand in close relation to the theory of burning, which was largely developed in this Institute.

Prof. Sokolik and his associates not only extended the theory in this direction but have also drawn from it a number of practically important conclusions.

The theory of the slow propagation of the flames with reference to chemical kinetics was first developed by Lewis in the United States (1934). Seldovich and Frank-Kamenetzky of this Institute extended this work by developing a consistent theory of the slow propagation of flame. The validity of the theory was shown experimentally by Baliaev (burning of liquid nitroglycerine), by Semenov and Seldovich (burning of carbon monoxide) and by Kokachashvili and Seldovich (burning of a mixture of hydrogen and bromine).

Just as with thermal self-ignition (calculation of the temperature of self-ignition from kinetic data of the slow process), so in the present case we were able to calculate the absolute value of the rate of flame-propagation in addition to its dependence on temperature, pressure and composition. Seldovich also developed the theory of various practically important phenomena such as limits of inflammation and detonation. He also completed the theory of the detonation wave, which previously had not been brought into relation with the rate of the actual chemical process.

In this way the phenomena of burning were correlated with chemical kinetics. Burning differs from slow reaction only in one respect—the powerful liberation of heat, and the hydrodynamic phenomena associated with it, influence profoundly the rate of the chemical process. To take these influences into account offers great mathematical difficulties. In developing the theory these have been overcome to a considerable extent, and the formulæ derived from the theory have been verified by experiment.

Concurrently with studies on the burning of gaseous systems, Prof. Khariton's group carried out extensive work on the burning and detonation of explosives. The results obtained are also of fundamental importance. Here also many new phenomena have been observed, and the theory has been clarified, but this domain still requires further theoretical work.

It cannot be assumed that we have reached complete certainty in the theory of burning, or that no unsolved problems will remain in this field of research. Here, as in the theory of chain reactions, a solid basis has been laid, the physical meaning of the processes has been clarified, and the method of approach established. Nevertheless, each individual reaction requires a special study, its specific character being different.

In this way we have worked step by step during the last twenty-five years in developing chemical kinetics in close contact with the English and American men of science who have frequently attended our conferences or sent us their papers.

Now our work has been interrupted. Many young workers of this Institute voluntarily joined the army during the first days of the War; one of my closest associates and followers, P. Sadovnikov, whose name is known among scientific circles of Great Britain, has been killed. But the majority of our collaborators are still in the laboratories of the Institute, where work has been greatly intensified.

HYDRO-ELECTRIC DEVELOPMENT IN SCOTLAND

On October 27, 1941, the Lord Advocate for Scotland, then the Right Hon. Lord Cooper, was appointed chairman of a committee of five to inquire into a report on hydro-electric development in Scotland. The report now issued* is dated August 24, 1942—so the Committee wasted no time. The Committee recognizes that hydro-electric planning is a matter for many years ahead—though it may not be out of place to remark that the national grid in Great Britain is an established success for war as well as peace conditions.

In the historical survey, the record of the last twenty years, with its six successive abortive promotions, comes boldly and badly into the picture. All major issues of policy, both national and local, have tended to become completely submerged in the conflict of contending national interests. But even governments do not escape if their policy is that they will neither develop the resources themselves nor allow anyone else to do so.

Excluding all burghal areas, the overall density of population on the mainland of the Northern Area is less than 20 per square mile. Northern Scotland is the only part of Great Britain not covered by the Grid scheme. The Committee finds that for such an area the policy embodied in the 1926 Act (which led to the formation of the Central Electricity Board) is essentially inappropriate and inapplicable. The progress of the Grampian Company, the control of which was obtained by the Scottish Power Company, in 1927, is traced. By supplying 106 million units per annum to the Central Electricity Board, the Grampian Company has an assured market to enable it to embark on a general supply in an extensive and sparsely populated territory. In 1940, the units sold, other than to the Central Electricity Board, totalled 63 million at an average of 1·55*d*. per unit. Here, then, is indicated a practical way for development. The Committee considers these results to justify the decision of the Electricity Commissioners and Central Electricity Board in 1931 to leave the development of this area to the Grampian Company.

Commenting on the criticisms against the Grampian Company, the report shows a sympathetic appreciation. Even so, doubts may still exist. On one occasion, when the present writer was visiting the Loch Rannoch and Tummelbridge Works, it struck him as strange to see two joiners making a coffin by candlelight in a house in the village of Kinloch Rannoch.

In the existing state, it is stressed that it will be essential at the earliest possible date to provide a substantial new source of power in the extreme north of the Grampian territory, to meet normal expansion. To construct a large steam station in a district so remote from coal and so rich in water-power would involve a major error of misplanning. It is not agreed that the cancellation of the bulk supply to the Central Electricity Board would solve the problem, both because of the effect of the loss of the contract, and the fact that Loch Rannoch and Tummelbridge Works have been designed for a 50 per cent load factor and not for supplying a general demand.

In the study of comparative costs of steam and hydro-electric generation, attention is directed to the rising price of coal in recent years, and in the fall in the basic rate of interest—the main components in the cost of electricity generated from steam and water respectively. On the financial side, the Committee considers its recommendations preferable to the provision of an equivalent capacity of new steam plant. Any likely improvement in water or steam-power technique is unlikely to influence the position. Provisional estimates disclose some seventy favourable schemes in the Northern Area capable of yielding not less than 4,000 million units per annum, or 450,000 kW. continuous.

Of the opposing theories for revitalizing the Highlands, the Committee regards the introduction of modern industries in which an abundant supply of cheap electricity is indispensable as the only means of securing a prosperous population in the area. These industries are electro-chemical and electro-metallurgical: calcium carbide and cyanamide; reduction or refining processes for aluminium, copper, zinc, vanadium and cadmium; the ferro-alloys. The defeat of the Caledonian Power Bill is regarded as a tragic mistake, not only for Scotland but also for Great Britain. Assuming that these industries on a substantial scale are essential to Great Britain, northern Scotland offers the only solution. By suitable planning, natural beauty can be preserved. The Committee challenges the critics to offer any other scheme to arrest the growing decay in the Highlands.

From independent computations, it is found that the ultimate local demand for general supply represents about 8 per cent of the ultimate power capable of development; consequently the position for the local population would be adequately safeguarded. In the long-term plan of development, the national grid forms the indispensable background as a market for surplus power.

The Committee's recommendations include the creation of a non-profit-earning, public-service corporation to work in close partnership with the Central Electricity Board. This new corporation would be responsible for the further development of electricity generation, transmission and distribution in the Northern Area. The corporation should attract to the Highlands a share of the industries demanding abundant and cheap power, develop such further power as may be required, and develop on an experimental basis isolated schemes in isolated districts. Local requirements should be given priority.

---

* Scottish Office. Report of the Committee on Hydro-Electric Development in Scotland. (Cmd. 6406.) Pp. 38. (London and Edinburgh: H.M. Stationery Office, 1942.) 9*d*. net.

The Committee also considered the safeguarding of fishery interests; the need for compulsory powers, the present inequitable valuation and rating of hydro-electric undertakings, and the preservation of the amenities.

From the foregoing digest of the report, it will be seen that the Committee has not only considered all relevant matters, but has also taken into account the views of opposing interests. A careful examination of the report leads to the conclusion that this is the first complete study that has been made of this matter, and that the general conclusions reached are the only sound ones possible.

S. Parker Smith.

OBITUARIES

Dr. C. Tate Regan, F.R.S.

Charles Tate Regan, formerly director of the British Museum (Natural History), who died on January 12, was born at Sherborne in February 1878 and was educated at Derby School and Queens' College, Cambridge. The choice of Derby was probably influenced by the fact that his parents were professional musicians, for the head-master at that time was J. R. Sterndale-Bennett, a son of the composer, and music took a serious place in the life of the School. The appreciation of great music thus inherited and cultivated gave Tate Regan great pleasure in later years. It was L. J. Fuller, the science master at Derby, who first suggested a career at the Natural History Museum to the boy, among whose interests natural history was already prominent, and Tate Regan stayed a fourth year at Cambridge to wait for a vacancy to occur at South Kensington. At Cambridge he studied under Sedgwick, and he worked and played with equal zest. He played both Association and Rugby football, and was a good sprinter, hurdler and jumper. At this time he was uncertain whether to specialize in plants or animals, but of one thing he was sure, that his interest would be in the structure of living organisms, and its bearing on their relationships and evolution.

In 1901 Regan joined the staff of the British Museum (Natural History). Günther, who was then keeper of zoology, advised him to specialize in fishes, and he joined G. A. Boulenger on this group, starting, at Günther's suggestion, with a revision of the family Stromateidæ, which was the subject of his first paper (1902). Boulenger had just received the proofs of the "Cambridge Natural History" volume on fishes, and asked his young colleague to look through them. Regan suggested that the Gadoidea were wrongly placed and Boulenger challenged him to prove it, finally accepting Regan's arguments (published in 1903) and altering the book accordingly. Regan would tell this story in later years, wondering at his own temerity.

From this time on, every year saw a long list of titles under Regan's name in the *Zoological Record*, and one is left amazed at the mental energy that allowed him to work on so many lines at once. His most important contribution to ichthyology was the series of papers on the major classification of living fishes, beginning with the "Classification of the Selachian Fishes" (1906) and continuing with the Teleostean orders and sub-orders, which were treated severally in some score of papers appearing in the *Annals and Magazine of Natural History*, mainly during the years 1911–13. This work was based on the study of a big collection of dried skeletons and on spirit specimens, and was written in a form and style so concise as to give little idea of the amount of research behind it. It is summarized in articles on selachians and fishes in the fourteenth edition of the "Encyclopædia Britannica", and presents a classification which is accepted as a basis by serious ichthyological workers all over the world.

In 1911 there appeared a work of a very different type, "The Freshwater Fishes of the British Isles". This is perhaps the most fascinating of Regan's works, combining as it does the results of intensive studies in the museum with knowledge gained in delightful days spent angling in the rivers and streams near his home in Dorset, and in visits to the English and Scottish lakes that harbour the relict char. At once authoritative and readable, this is a model book of popular natural history.

It fell to Regan's lot to write the section on fishes in the "Biologia Centrali-Americana" (1906–8) and to report on the fishes of the Antarctic expeditions of the *Scotia* (1913) and *Terra Nova* (1914, 1916). From these results syntheses were made which increased considerably our knowledge of the laws governing the geographical distribution of fishes. His conclusions on this subject, too, are gathered together in an "Encyclopædia Britannica" article. Regan's systematic revisions of families are many, and in every case have that masterly quality which has put subsequent work upon a sound basis, and has been a powerful influence in keeping the standard of systematic ichthyology high.

I first met Dr. Regan in 1921, when as a student I visited the Museum to learn something about the classification of fishes, and received unstinted help. Regan had then just become keeper of zoology. When, in 1927, he was appointed director, he found that administrative duties left him little time for scientific work. He was able, as always, to do a great deal in the evenings, but he needed a collaborator who could deal with the practical work on the collections all day, allowing him to follow it in what time he could spare, and in the following year I was appointed as his scientific assistant. He had already, in 1925, dealt with the deep-sea angler-fishes of the first *Dana* expedition, and had described for the first time the dwarfed and parasitic males of this group. He was now about to tackle the *Dana* Stomiatoid fishes, and had also large collections of African Cichlidæ to work out. I soon understood that I was highly privileged to work upon such material under the guidance of such a man, and my admiration for his outstanding brain, his memory, his enthusiasm and drive grew with our association. With the second collection of *Dana* deep-sea angler-fishes, we elaborated together Regan's earlier discovery of the parasitic males. Parr's announcement that some males were dwarfed but free-swimming came when we were already working on this collection, and was not a surprise, and the *Dana* material made it possible for us to relate the free males to their extremely dissimilar mates. This work gave Regan special pleasure, as also did his earlier discovery of the nature and structure of the complicated copulatory organ of the minute East Indian fishes of the family Phallostethidæ. The latter work appeared in 1916, the year before his election to the Royal Society at the age of thirty-nine.

Although he was a good systematist, Regan never mistook the minutiæ of taxonomy for an end in themselves, and his outlook is well summarized in the following quotation from his address on "Organic Evolution" before Section D (Zoology) of the British Association in 1925: "Every good systematist must feel some satisfaction when he has written a diagnosis that is diagnostic, or has made a key that will work; but this satisfaction is small compared with that which he feels when he has reason to think he has settled the position of some doubtful form, or has discovered the origin of a group and the lines of evolution within it. The main interest of systematic work lies in the fact that it is a study of the results of evolution, and that from such a study one may hope to get some light on the meaning of evolution".

Regan found in the fishes ample scope for his energies, but his interests extended beyond, and especially into other vertebrate groups. His interest in the geographical distribution of animals led him to suggest to other specialists lines of research on the interrelationships of frogs and the classification of mammals. He was convinced, moreover, that false ideas were prevalent as to the origin and classification of the primates, including the ancestry of man, and in 1930 he published a preliminary statement of his views. He followed this by an elaborate investigation into the structure and relationships of insectivores and lemurs, and left unfinished manuscripts and drawings which it is greatly to be hoped will be put into order and published. Of recent years, too, he had embarked on a general classification of the fish-like vertebrates, and, to clear up a doubtful point, had undertaken an investigation of some fossil forms. This paper also was left unfinished.

In addition to his scientific work, Regan performed important services for the British Museum (Natural History) as keeper of zoology and director. His first duty on taking the directorship was to give evidence before the Royal Commission on Museums, and as a result of this the Commission recommended increases of staff and of buildings. The increase in staff, though delayed, was finally accomplished, but the financial crisis of 1931 interfered with the plans for building to such an extent that the War found them still only partly carried out. It is sometimes thought that Regan had little interest in the exhibition side of the Museum. This was not so, but his large-scale ideas were bound up with the new building plans, and were never even put on paper.

Regan had the gift of lucid expression, founded on clear and concentrated thinking, and he enjoyed talking on a subject that interested him. He was a member of the Royal Society Dining Club and often entertained his fellow "royal philosophers" over their port with an account of his latest discovery, illustrated by specimens and drawings. Many an impromptu lecture, which would have delighted a class of students, has been reserved for my unworthy ears at South Kensington, illustrated by drawings on the back of an envelope or an empty cigarette packet.

Tate Regan was an honorary fellow of his College, received the degree of D.Sc. *honoris causa* from the University of Durham, and was *Academico Honorario* of the University of La Plata. He was a foreign member of the Royal Danish Academy, of the American Academy of Arts and Sciences, and of the American Society of Ichthyologists and Herpetologists; the Geoffrey de St. Hilaire Medal was awarded to him by the Société Nationale d'Acclimatation de France.

Regan's outstanding qualities were generosity and frankness, which endeared him to his friends, and an enthusiasm and energy which made him, like the sprinter he was in his youth, go all out for some desired objective, and left him the victim of a too severe disappointment if it failed him. He was a keen gardener and enjoyed watching a good game of football or an athletic contest. His friends mourn a rare and stimulating companion.

Sincere sympathy goes out to Mrs. Regan and their four children, one of whom is now a prisoner of war.

E. TREWAVAS.

Dr. Nikola Tesla

NIKOLA TESLA, who died on January 7, was born in 1857 at Smiljan in Croatia. His father, a Serb, was a clergyman of the Greek Church; his mother is remembered as very inventive and is credited with making improvements in churns, looms and other rural machinery. Nikola, while at school, began to make electrical experiments, and finished his formal education in the engineering faculty of the Graz Polytechnic School. After a period in the Government telegraph department at Budapest, he joined the Edison concern in Paris and went to the United States about 1883. Here he worked under Edison for a time, but soon set up his own firm for the manufacture of arc lighting plant.

At this period the applications of electric power in industry were effected mainly by direct current, but many inventors were attacking the problem of making motors suitable for use with alternating current. Tesla in the United States and Ferraris in Italy each published in 1888 the results of several years of independent work on motors utilizing rotating magnetic fields produced by two-phase currents. Both inventors envisaged machines in which the rotor is propelled asynchronously by means of currents induced in it by the rotating field, and Tesla described also motors in which the rotor is pulled round in synchronism with the rotating field. Neither type need employ brushes or commutators. These rotating-field motors, together with the introduction of polyphase currents, proved to be the solution of the problem of using alternating current in factories. In addition, by 1890, Tesla also invented methods of starting and running motors on single-phase current. His designs were so sound that his larger machines attained efficiencies of 95 per cent. Having completed his task, he disposed of his patents to the Westinghouse Company and dropped the subject.

Hertz's work was directing attention to high-frequency alternating currents, so Tesla turned to the problem of generating these currents on an engineering scale. First he designed and built a succession of alternators, and by 1891 attained a frequency of 30,000 cycles per second. He studied the properties of these currents in circuits possessing distributed inductance and capacitance, and developed tuned coupled circuits for enhancing their voltage by resonance. For higher frequencies he employed the discharge of condensers through induction coils, obtaining big powers by aid of rotating dischargers or magnetic blow-outs at the spark gap. On coupling the primary circuit to a resonant secondary circuit comprising metal areas, large flaming and streaming ionization currents were obtained in air and in Geissler tubes. Ionic bombardment was observed to produce brilliant phosphorescence, and sometimes fusion, of solid matter.

But Tesla's main purpose was the transmission of power and messages across space. In 1892 and 1893 he developed his scheme. High-frequency power was to be led to a large antenna consisting of an elevated metal area connected by a vertical wire to a large metal plate buried in the earth. The receiving antenna was to be equal in every respect. The figure in the *Journal of the Franklin Institute* shows the source of oscillations connected into the vertical wire near the earth at the sending station, and the receiving apparatus in the corresponding place at the receiving station. He did not patent the antenna. Tesla states his belief that the electrical oscillations will be propagated along the surface of the earth and that they may be assisted by an upper conducting layer of the atmosphere—this is eight years before Heaviside and Kennelly. Tesla had thus supplied, two years before wireless began its commercial career, all the elements of both spark and continuous wave sending stations. For the receiving station the Lodge or Branly coherer was already available for spark telegraphy, but Tesla concentrated on continuous waves because he was more interested in the transmission of power than in the transmission of messages. After building one or two small stations, he started in 1897, at his own expense, a station of 200 kilowatts in Colorado. From this point in 1899 he transmitted power enough to light a lamp at 30 km. For the reception of continuous wave signals he invented the interrupter device known as a ticker, which was employed by others for the next dozen years, and from the Colorado station received signals at a distance of 1,000 km. Later, his form of antenna, his rotating discharger, and his tuned transformer were used successfully by many others at spark stations in every country.

Space limits this survey to a few of the new things which Tesla's creative imagination and constructive genius gave to the world. His other inventions include pyro-magnetic generators, thermo-magnetic motors, unipolar dynamos, meters, lamps, mechanical vibrators of huge power and a variety of instruments. Some seven hundred patents stand in his name, mostly taken out before he was fifty years of age. Apparently his method of work was to state a problem, devise solutions, build machines and file a patent specification or, possibly, read a paper to a technical society. Then he would start on a new problem. It happened that one of his subjects, high-frequency discharge, made a brilliant display, and he was persuaded to lecture upon it several times. The demonstrations were perfect and very showy; consequently sober folk concluded that Tesla was somewhat of a showman. This is quite wrong. Throughout his long life of eighty-five years, Tesla seldom directed attention to his own successes, never wrote up again his old work, and rarely claimed priority though continually pirated. Such reserve is especially striking in a mind so rich in creative thought, so competent in practical achievement.

W. H. ECCLES.

Dr. A. L. Lowell

OF the two late presidents of Harvard, Eliot and Lowell, it was said that Eliot found Harvard a college and built upon it a university, while Lowell found a university and unearthed its college. Eliot developed great post-graduate schools, from medicine to business administration; but his free elective system for undergraduates left the college almost spineless. It was for his successor to revalue the meaning of a B.A. degree, and he did.

The chief monument of Lowell will be his scheme of concentration (reading one main subject) and his general examination (final schools). Anglophile in nothing so much as in education, he had always approved of this method, nearly identical with that of Oxford and Cambridge, but had to watch the previous regime spare the rod and spoil the undergraduate. In the last decade of Eliot's reign, most pupils used to scoff at honours; in the last decade of Lowell's, the tendency was to scoff at those unequal to reading for them.

The second great change under Lowell was likewise of British pattern. He broke up an unwieldy university into colleges, again like Oxford and Cambridge. Long a cherished plan of his, he lacked funds for it, until one day about fifteen years ago a stranger called at the President's office. Lowell, in the midst of a busy morning, almost did not see the caller—a certain Mr. Harkness. "If," said the stranger, "you suddenly had a lot of money given you—let us say millions—for the university, what would you like to do with it ?" Lowell actually produced a set of blue-prints from a drawer. "Build separate colleges," said he promptly. "Exactly my idea," responded Harkness. "Yale, where I come from, has declined such a gift. Will you take it, and how much do you need ?" The result was the seven 'Harvard Houses' —built either entirely new or to include conversion of several hostels already in use—at the cost of 3½ millions sterling. (Yale then changed its mind, whereupon Harkness cheerfully donated enough more to Yale for a similar project. It was Harkness funds, of course, which also came later to Great Britain for the Commonwealth Fellowships and for the Pilgrim Trust.)

The third milestone in the presidency of Lowell was once more inspired by the example of England. He founded in Harvard the Society of Fellows, an adaptation of All Souls, Oxford. Under this foundation—the funds said to have been given by Lowell, himself a wealthy man—a committee of senior fellows, members of staff in Harvard, elect each year eight junior fellows, graduates of any American university of standing, for postgraduate research. These fellowships yield enough to cover all expenses of the holder, and are renewable (from three to six years) until his specific problem of research is completed. He has the utmost freedom, being not required to work for a degree. Junior fellows live in the various 'Houses', and in time may be offered appointments to the staff.

As the most important personality in American education in his time, Lowell exerted a national influence. So appreciative of his leadership were benefactors, whether old Harvard men or not, that during his own tenure of office—twenty-four years—he saw the endowment of his University tripled; when he retired in 1933 it stood at some thirty millions sterling. A dozen books which Lowell wrote will ensure him remembrance as an authority on government—government in America, in Great Britain, and on the Continent; but his annual reports, as president, to the Overseers of Harvard, are essays in the advance of education, not at Harvard only, but also throughout America.

Lowell died on January 6 at the age of eighty-six.

WILLARD CONNELY.

NEWS and VIEWS

British Association

Conference on Science and the Citizen

THE British Association, through its Division for the Social and International Relations of Science, is arranging a conference on Science and the Citizen: the Public Understanding of Science, to be held on Saturday and Sunday, March 20 and 21, at the Royal Institution, Albemarle Street, London, W.1, by kind permission of the Managers. The Conference will be opened by Sir Richard Gregory, president of the Association, and there will be four sessions, the subjects of which will be the exposition of science, radio and cinema, science as a humanity, and science and the Press. The chair will be taken, at the successive sessions, by Sir Henry Dale, president of the Royal Society and director of the Royal Institution, Sir Allan Powell, chairman of the governors of the B.B.C., Prof. J. L. Myres, and Sir Richard Gregory. It is hoped that an exhibition of films of scientific interest will follow the session on radio and cinema. A list of speakers and other particulars will be issued in due course, and these and tickets of admission will be obtainable from the British Association, Burlington House, London, W.1. The Association, in arranging this conference, is continuing its policy of dealing, by this and other methods, with subjects of especial importance in relation to post-war reconstruction, which were touched upon in the course of the conference on "Science and World Order" held in September, 1941.

Dr. Godfrey Rotter, C.B., C.B.E.

DR. GODFREY ROTTER has recently retired from the post of director of explosives research, Woolwich, after about forty years in Government service. Having graduated from the University College of North Wales, Bangor, he entered the then Experimental Establishment of the War Office in 1903; for the last twenty-one years he has been the head of the Directorate of Explosives Research. Before the War of 1914–18 he had proved his capacity for design, and he received an award for his part in the design of the 106 Fuze, of which nearly a hundred million were made. As a chemist, he showed his skill in devising apparatus for the study of the properties of explosives, of which that for the determination of their sensitiveness is the standard instrument to-day. During 1914–18 he took his full part in the invention and development of new high explosives and propellants, so that when Sir Robert Robertson left in 1921 he succeeded him as director. Of his achievements during the last twenty years it is impossible at this time to speak, but it may be said that he has been associated with notable advances. Of an engaging disposition, and giving an example of an extraordinary capacity for hard work, in an endeavour to keep abreast of ever-increasing activities, he retained the affection and respect of all his staff. He is succeeded by Prof. S. Sugden, of University College, London, who was a member of the Department during the War of 1914–18.

Prof. S. Sugden, F.R.S.

PROF. SAMUEL SUGDEN, who has been appoin superintendent of explosives research, Royal Arsenal, Woolwich, for the duration of the War, has been since 1937 university professor of chemistry, University College, London. Prof. Sugden's massive achievements in research cover a wide field. His native inspiration led to the discovery of a property related to the molecular volume and known as Sugden's parachor. This inspired chemical investigations all over the world, and supplied much valuable information regarding the constitution of chemical compounds and the nature of valency linkages. In his book "The Parachor and Valency", published in 1929, he gave a masterly account of the subject. He has made notable contributions to magnetochemistry. For example, when Pauling concluded from wave mechanics that bivalent nickel, palladium and platinum, unlike the non-transitional elements, can form 4-covalent compounds of plane type which can further be distinguished by their smaller paramagnetic moments, Sugden supplied the first experimental evidence to support this view. It is significant of his keen interest in this field of investigation that he has selected magnetochemistry as the subject for the ninth Liversidge Lecture which the Chemical Society has invited him to deliver. Further evidence of the great fertility of Sugden's researches is found in his investigations on dipole moments, induced radioactivity and the rare earths. He was elected a fellow of the Royal Society in 1934. His powers as a thinker and investigator allied with a flair for exposition have earned him distinction as a scientific writer and teacher.

Institution of Electrical Engineers Awards

THE council of the Institution of Electrical Engineers has elected the Right Hon. Lord Hankey to be an honorary member of the Institution. This distinction has been conferred upon Lord Hankey in appreciation of the valuable services rendered by him as chairman of the Scientific and Engineering Advisory Committees of the War Cabinet, and more recently as chairman of the Technical Personnel Committee. In the latter capacity he has dealt with many problems which have arisen in meeting the demand for engineering personnel for the Forces, the supply establishments and for industry, and has been instrumental in establishing special schemes, notably the intensive training scheme, State bursaries and the engineering cadet scheme, for the training of engineers to meet the needs for future personnel.

The Faraday Medal of the Institution has been awarded to Sir Archibald Page, honorary member and past president of the Institution, in recognition of the outstanding services rendered by him in the sphere of electricity supply, and especially for the prominent part he has taken in the planning, construction and operation of the national grid system in Great Britain, the establishment of which has proved of such inestimable value in the prosecution of the war effort. The Faraday Medal is awarded by the Council of the Institution not more frequently than once a year, either for notable scientific or industrial achievement in electrical engineering or for conspicuous service rendered to the advancement of electrical science, without restriction as regards nationality, country of residence, or membership of the Institution.

Chemists in Great Britain

A MEMORANDUM to which are attached the signatures of many of the leading chemists, pure and applied, of Great Britain, has recently been circulated.

It is addressed, by members of bodies concerned with the interests of chemists and chemistry, to fellow-chemists, and it asks for increased collaboration between the respective bodies in the form of a federal body "to administer and guide, in accordance with the clearly-expressed will of its members, all the main activities that concern chemists as professional men and working scientists". Whatever the body created for such a purpose, its chief functions would be related to: (1) publications for the exchange and dissemination of chemical knowledge; (2) scientific meetings for the discussion of problems under investigation and for the survey of specific fields of knowledge; (3) libraries, both central and regional; (4) qualification, directed to the maintenance of a high standard of professional competence and of such methods of registration as the profession may decide, whether this registration have *de jure* or only *de facto* recognition by Government; (5) publicity, to ensure that the general public be accurately informed of what chemists and chemistry are doing and could do for the benefit of the community; (6) social security, whereby the economic position and the legal interests of all chemists may be safeguarded; (7) social functions.

A common secretariat, a central house, and close co-operation in all centres between bodies representing chemists are believed to be necessary for the discharge of such functions. As a first step in this direction, the councils of the Chemical Society, the Society of Chemical Industry and the Institute of Chemistry are asked to consider and report immediately on how to expedite the action advocated and to obtain advice as to whether the agreement constituting the Chemical Council can be amended so as to enable the Council to function as a central organization such as that envisaged. Should it be found that the Chemical Council cannot undertake the new functions suggested, it is asked that a new federal body be set up at once, to enable chemists to take their proper part in planning and building the post-war world.

The First Man-Carrying Aeroplane

The Smithsonian Institution, Washington, has recently issued a pamphlet which settles a controversy that has existed for many years. It is universally acknowledged that the Wright brothers were the first to make sustained flights in a heavier-than-air machine at Kitty Hawk, North Carolina, on December 17, 1903. Earlier in the same year a machine built by Samuel Pierpont Langley was reported to have flown, and this was exhibited in the Smithsonian Museum with the label that this "Was the first man-carrying aeroplane in the history of the world capable of sustained free flight". These reported flights had never been officially observed, and in the light of later aerodynamic knowledge it was debatable whether the machine could have accomplished sustained flight under its own power. In order to settle this matter, the Institution reconditioned the machine in 1914, when it was flown successfully, but the fairness of the test was challenged on the grounds that vital alterations were introduced during this rebuilding, which improved its aerodynamic and structural characteristics sufficiently to allow it to be capable of flight. It was claimed that without these changes, based on knowledge that was not available in 1903, the machine could not have flown. These claims have since been upheld by experts, and the Smithsonian Institution has now issued a statement on the results to Dr. Orville Wright and changed the wording of the label on the Langley machine accordingly. Although the detailed explanation has only just been issued, the description on the exhibit was altered in 1928. As a result of this misrepresentation, the Wrights lent their original machine to the Science Museum at South Kensington, where it has been exhibited for many years. The Smithsonian Institution has expressed a hope that Dr. Wright will now consider bringing it back to the United States, where it will be given "the highest place of honour in the United States National Museum".

Meteors Seen in the United States

J. Hugh Pruett has written an account of a detonating meteor (Ast. Soc. Pacific, Leaf. No. 165, Nov. 1942) under the title, "The Portland Meteor and Resulting Meteorite". The meteor was seen soon after 8 a.m. on July 2, 1939, and was not only a conspicuous fireball, but was also responsible for a panic among many people in Portland, Oregon, owing to the jarring of the houses while it passed over the town. From data supplied by a number of observers, it was found that the fireball became visible near the northern Oregon coast-line, and passing over northern Portland, disappeared beyond Bonneville at a height of 10 miles. It was moving in a direction opposite to that of the earth in its orbit and for this reason had a fairly high velocity—probably 40 miles a second. Next day a portion of the fireball was picked up on a farm near Washougal, fifteen miles east of Portland, and it was found that it belonged to the type of stony meteorites known as Howardites. Although search parties were organized, no other pieces were found; but it is fairly certain that the Washougal portion, weighing 225 gm., is not the only fragment which reached the earth. Howardites are described as friable and easily destroyed because the material composing them is cemented together rather loosely.

Another meteor is described by Oscar E. Monning in *Sky and Telescope* (November 1942). It appeared on August 7, 1942, at 9.30 c.w.t., when it was still twilight in the more western regions of its flight, and its magnitude was estimated to be —4. When first seen it was some miles north of Shreveport, and its height then was about 80 miles. In 30 sec. it had moved to a point less than 20 miles north and east of Guymon. Its length of flight may have been 600 miles and its motion was nearly horizontal, as its total drop was about 65 miles during this long flight. It had a long tail and left an evanescent train which was 30° in length as seen from some places, but it persisted for only 5–10 sec. No fragments of the meteor have been found and there were no detonations, so far as present evidence is available, but it is possible that additional information will be obtained which may assist in elucidating further important facts about this bright meteor.

New Projector for Navigational Stars

James R. Benford has given a description of a Bausch and Lomb artificial star projector recently installed at the United States Air Station, Pensacola, Fla., which overcomes many of the difficulties of star charts (*Sky and Telescope*, November 1942). The instrument is located in the centre of a hemispherical dome upon which it projects images corresponding to 145 navigational stars. The instructor and the students sit inside the dome at a level a little below that of the star projector, which makes the stars appear in the darkened room as points of light in a twilight sky. As the projector rotates on its axis once in 20 minutes, the stars swing slowly across the face of the dome in this time, and students are able to gain true impressions of the form, location, and interrelations of the constellations much more clearly than they can from star charts. The apparatus supplies the nearest approach to the actual study of the heavens from outdoor instruction. The latter is not always a satisfactory method when large groups of students have to be considered, and in addition, weather conditions and the season of the year are disturbing factors. The star projector is a most important adjunct to-day in pilot training when speed is so essential.

Effects of Altitude

According to the *Journal of the American Medical Association* of October 24 a law was recently passed by the Senate of Argentina for the creation of a committee to supervise studies on the effects of altitude. The committee, which will consist of medical men, chemists, physicists and biologists, will form a branch of the Ministry of Internal Affairs. The field covered by the committee will be (1) biological problems in relation to the most adaptable human biotypes; (2) working capacity, feeding, housing and climatological, hydrological, geological, zoological, botanical and physiochemical factors in relation to the life of normal men in various altitudes; (3) pathology of altitudes, studies of diseases which may be improved by hypsotherapy, and the establishment of sanatoria and hospitals and proper altitudes for the cure of certain diseases; (4) creation of portable laboratories and establishment of experimental hypsological centres; and (5) studies of the animals and plants of different regions, the constitution of the soil and meteorological phenomena.

Folk-Lore of Children's Diseases

At a meeting of the Folk-Lore Society on January 20, Dr. J. D. Rolleston read a paper on the folk-lore of children's diseases. The field is extensive, since it covers the popular conceptions of the acute exanthemata and other infectious diseases, especially whooping cough and diphtheria, venereal infections, cardiac, respiratory, alimentary disorders and isolated diseases, especially enuresis, infantile convulsions, rickets, hernia and the supposed effects of the 'evil eye'. As regards causation, belief in the doctrine of maternal impressions is still far from extinct, although there is no scientific foundation for such a view. The recognition of astrology by orthodox medical practitioners survived until the eighteenth century, as was shown by Mead's work. The visitation of the 'evil eye' also accounted in popular estimation for many diseases, especially in countries bordering on the Mediterranean. Although a vast number of more or less irrational and inexplicable beliefs were connected with the newborn period, comparatively few of them were of medical interest. Dentition, like menstruation and pregnancy, is a normal process, and was much less frequently the cause of disease than was popularly supposed, especially by mothers who were liable to regard any of their infants' ailments as due to this cause. In like manner, tongue-tie, though often alleged by a mother to account for her child's inability to take the breast, was usually non-existent. The belief in the superstition that venereal disease could be cured by transfer to healthy young virgins of either sex was still prevalent, and was one of the chief causes of acquired syphilis or gonorrhœa in children. Although in other departments of medical folk-lore, especially dermatology, ophthalmology and otology, prophylaxis has received much less attention from the folk than curative treatment, in the case of children's diseases, much more importance seems to have been given to prevention than in other branches of folk-medicine. Examples of the kind were the use of salt for guarding the newborn against evil demons and evil influences, the use of amulets and the administration of coral in the mother's milk.

Infant Mortality in the United States

In a recent article on infant mortality in rural and urban areas in the United States (*Public Health Rep.*, 57, 1494; 1942), Herbert J. Sommers, of the United States Public Health Service, states that the infant mortality-rate in the registration areas of the United States has been reduced by more than a half. From 1915 until 1929 the urban rate, though higher than the rural in every year, decreased more rapidly than the rural, so that in 1929, for the first time on record, the rate was lower in urban than in rural areas, and since then the urban rate has remained lower than the rural. The rates were generally higher in the south than in other regions and rural rates were generally highest in the Middle West. The reduction in infant mortality which has taken place in cities is to be attributed to increasing emphasis being laid on the principles of sanitation, the establishment of 'well-baby' clinics, the increasing use of hospitals for delivery, the compulsory pasteurization of milk and the application of modern medical knowledge.

Physical Education

In a lecture delivered before the Anglo-Swedish Society and published in the December issue of the *Anglo-Swedish Review* on the development of physical education in Great Britain and the Dominions, Miss P. Spafford, organizing secretary of the Ling Physical Education Association, said that organized physical education in Great Britain and the Dominions originated in the elementary schools, while the educational, medical and recreative gymnastics were based on Per Henrik Ling's principles. In newly built schools throughout the country conditions for physical education are excellent. Many have their own swimming bath as well as a field for games and a gymnasium. The physical education scheme in schools in Canada, South Africa, Australia and New Zealand is largely that carried out in British schools. The War has inevitably caused a certain set-back in physical education owing mainly to a shortage of gymnastics and game schooling as well as a lack of gymnastics equipment. The most popular physical activity in all the countries of the British Commonwealth is swimming. Physical training in the Services is based on the Swedish and Danish systems and is closely linked up with recent research in physiology and psychology. Until recently there has been little or no organized physical training in the universities, although there has always been sport of various forms. There is a real need for further instructional co-operation, and further research is essential, especially into the physiological basis of exercises.

Medico-Dental History of Cloves

The issues of *Dental Items of Interest* for June–October 1942 contain an interesting and scholarly article on this subject by Dr. Eugene J. Molnar, research associate of the Northwestern University Dental School, Toledo, Ohio. Originally, cloves were first used in the East Indies, India and China. After the decline of the Roman Empire the medical use of cloves was introduced into Byzantium, probably owing to its proximity to the East. The practice of using cloves for the treatment of dental caries, which developed in the middle of the sixteenth century, was introduced from extra-dental sources, namely, laymen, amateur botanists, apothecary-grocers and others. Eugenol, which was first extracted from oil of cloves by Ettling in 1834, received its name from Cahours in 1858, and is widely used in dentistry for the relief of pain. Its exact pharmacological properties for the treatment of caries and odontalgia have received considerable attention, but have not yet been fully determined. The action of eugenol in zinc-oxide-rosin cements, which form the best temporary filling material, also remains unknown.

Larch and Scots Pine Poles

Results of tests carried out on British-grown poles suitable for transmission lines have been reported (*Electrician*, Jan. 22). The tests were made to measure the deflexion of the poles, rigidly supported at 5 ft. from the butt, for any given loading, up to the ultimate load, applied at 2 ft. from the top of the pole; to obtain a value for their ultimate breaking load, and to calculate the average value of fibre stresses. The poles tested were 36 ft. long by 11½ in. diameter at 5 ft. from the butt, with an average diameter of 8½ in. at the top. An analysis of the test results shows the deflexion for any given loading is much greater for Scots pine than for larch poles. On the other hand, the larch has a much greater ultimate strength, requiring an average load of 4,443 lb. compared with an average of 2,800 lb. for Scots pine. Other things being equal, it is apparent from these tests that, from a strength point of view, larch poles are much better for transmission line supports than Scots pine. The ultimate fibre stress of larch is much greater than that of pine, being of the order of 10,500 lb./sq. in., as against 6,500 lb./sq. in. in the case of pine. The figure for Scots pine is well below the generally accepted figure of 7,800 lb./sq. in. for Baltic fir.

The creosote penetration was found to be much better with Scots pine poles than with the larch. The poles were creosoted six days before the tests were carried out, and from an examination of the cross-sections, it appeared that the penetration in the larch poles varied between ⅜ in. and ⅝ in. with an average of ½ in., and in the Scots pine between 1 in. and 4 in. with an average of 2⅝ in. From the figures obtained it is evident that with the same loading and in order to maintain a given factor of safety, the span-length allowed with Scots pine poles should not exceed 63 per cent of the allowable span-length with larch poles; the ultimate fibre-strength of larch accords closely with the figure of 10,000 lb./sq. in. given in *B.S.* 513–1933; the ultimate fibre-strength of Scots pine is considerably below the value generally assumed for Baltic fir (6,500 lb./sq. in. as compared with 7,800 lb./sq. in.); there does not seem to be any relationship between ultimate load and the moisture content of the pole.

Otto Obermeier (1843–1873)

Dr. Otto Hugo Franz Obermeier, the founder of German parasitology and father of German tropical medicine, was born at Spandau in Prussia on February 12, 1843, the son of a non-commissioned officer. He received his medical education in Berlin where he studied under Du Bois-Reymond, Virchow, Langenbeck and Frerichs and qualified in 1866 with a thesis on Purkinje's fibres. While working in a laboratory at the Charité Hospital in Berlin he discovered in the blood of persons suffering from relapsing fever minute organisms presenting a twisting or rotatory movement. His first publication on the subject appeared on March 1, 1873, in the *Zentralblatt für die medizinische Wissenschaften*, and a few weeks later he gave an account of it at the Berlin Medical Society. His attempt to transfer relapsing fever to laboratory animals by intravenous or subcutaneous injection of blood from relapsing fever patients was unsuccessful. His promising career was cut short by a laboratory infection with cholera, and he died at the early age of thirty on August 20, 1873. The following year, at Cohen's suggestion, the organism which he had discovered was given the name of *Spirochæta obermeieri*.

Earthquakes Registered in Spain

During October 1942, twenty-four earthquakes were registered on the seismograms obtained at the Geophysical Observatory at Toledo. The greatest shock was on October 20 when, from an epicentre calculated to have been some 12,010 km. distant, an earthquake recorded *PPz* at 23h. 41m. 25s. U.T. and attained a maximum ground amplitude at Toledo of 170 μ. The shock finished recording at 01h. 30m. U.T. on October 21. Other strong shocks were on October 9 (max. ampl. 50 μ), October 26 (max. ampl. 27 μ) and October 28 (max. ampl. 2 μ). The earthquake of October 14 which began recording at Toledo with *ePz* at 8h. 26m. 45s. U.T. had an estimated epicentral distance from Toledo of 390 km. The epicentre may have been situated at lat. 38° 50′ N., long. 0° 55′ W., which is nearly 80 km. north-north-west of Alicante, and the focus may have been some 29 km. deep. Microseisms interfered with some of the interpretations during the month, all interpretations being provisional.

Disinfection of Cereal Seed

In reply to a question by Major Thorneycroft in the House of Commons on February 4, as to whether in view of the importance which the Minister of Agriculture and Fisheries attached to the increased production of spring cereals, he would consider making it compulsory on all farmers to disinfect their seed according to the best modern practice, Mr. Hudson said that he is anxious that all oat and barley seed should be dressed this spring with a mercury dressing to prevent disease but he prefers to rely on propaganda and advice rather than compulsion. War agricultural executive committees are carrying out campaigns to this effect.

Errata

In the article "Utilization of Glass", in Nature of February 6, p. 173, it should have been stated that the electrical resistance varies by "at least ten thousand-million-fold", and that plate glass is "rolled continuously eight to nine feet wide".

LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. No notice is taken of anonymous communications.

A Synthetic Differential Growth Inhibitor

It has been shown[1,2,3] that malt, ungerminated grain and oranges contain a water-soluble, thermostable substance which permits the free growth of epithelial tissues *in vitro* at concentrations at which it inhibits totally the growth of fibroblasts and other mesenchyme cells. In the present investigation, commercial malt extract has been employed, and the methods of biological assay with fragments of ten-day chick's heart have already been described[2,3]. Vigorous steam distillation of malt extract affords a distillate which contains a variety of substances among which, after suitable treatment, a differential inhibitor can be detected.

This was presumably derived from the original factor by hydrolytic fission, but, as it should be a relatively simple substance, attention was focused on its study as likely to provide a valuable clue. The compound is produced in such small quantity that it has not yet been possible to identify it with certainty; its properties and the analysis of derivatives indicated the probability that it is an unsaturated lactone, $C_6H_8O_2$.

A natural product of this composition and character is the so-called parasorbic acid (δ-$\Delta^{\alpha\beta}$-hexenolactone) which occurs in the berries of the mountain ash[4]; this dextro-rotatory substance has not yet been synthesized so far as we are aware. We have obtained *dl*-δ-$\Delta^{\alpha\beta}$-hexenolactone in small yield by condensation of acetaldol with malonic acid in pyridine solution (b.p. 116°/16 mm. Found: C, 64·6; H, 7·3. $C_6H_8O_2$ requires C, 64·3; H, 7·1 per cent); sorbic acid is the main product[5]. Benzoylation of aldol in pyridine solution followed by condensation with malonic acid afforded a solid mixture of acids, and from these by steam distillation and gradual addition of sodium hydroxide a mixture of δ-hexenolactone and benzaldehyde was obtained (Found after removal of benzaldehyde: C, 64·7; H, 6·8 per cent). δ-Hexenolactone exhibits the usual properties of an unsaturated substance and slowly develops acidity in cold aqueous solutions as the result of hydrolysis; it is unstable, becoming orange-coloured in air and light, and it displays a marked tendency to polymerize both as a lactone and as a derivative of an $\alpha\beta$-unsaturated acid. It readily forms a complex condensation product with 2 : 4-dinitrophenylhydrazine ($3 : 2 - 3H_2O$). It is completely removed from aqueous solution by charcoal, possibly in the form of a polymeride. In all these properties it resembles the lactone present in the malt extract steam-distillate.

Synthetic δ-hexenolactone exhibits the differential growth-inhibitory property: the two analysed specimens were active at a concentration of 0·011 mgm./c.c.; a specimen made by the first method and not distilled (avoidance of toxic decomposition products) was active at 0·006 mgm./c.c. A rough quantitative comparison with the malt distillate factor shows, however, that the latter is the more active. Three possibilities therefore arise: (*a*) that the malt distillate factor is optically active δ-hexenolactone, (*b*) that it is δ-hexenolactone and that other substances are accessory to the effect, or that the synthetic compound contains traces of toxic impurities; or (*c*) that it is another substance closely resembling δ-hexenolactone.

The discovery of the differential growth inhibition produced by δ-hexenolactone suggests that it is able to inhibit a growth factor which is more specifically required by fibroblasts than by epithelial cells, and an obvious provisional hypothesis is that the factor may be pantothenic acid, or an analogous substance. We are engaged in experiments designed to test this theory, the first step being the synthesis of δ-hydroxy-$\Delta^{\alpha\beta}$-hexenoyl-β-alanine.

A few further observations are that δ-valerolactone (dihydro-δ-hexenolactone) is non-toxic in the special sense and non-inhibitory. The malt extract distillate contains a highly toxic substance of salicylic acid type and several aldehydes (for example, acetaldehyde and furaldehyde) which are non-differential inhibitors.

Aldol and acrolein are toxic; crotonaldehyde inhibits all growth at a concentration between $M/3{,}000$ and $M/3{,}600$, whereas propionaldehyde and furaldehyde are much weaker inhibitors, the limiting concentrations lying between $M/150$ and $M/200$.

[5] The acid, $C_{12}H_{18}O_5$, described by Riedel (*Annalen*, **361**, 89; 1908) is doubtless a dimeride of δ-hexenolactone + H_2O, that is, *O*-δ-hydroxy-$\Delta^{\alpha\beta}$-hexenoyl-δ-hydroxy-$\Delta^{\alpha\beta}$-hexenoic acid.

The Saponin of Fenugreek Seeds

The presence of a saponin in the seeds of *Trigonella Foenum græcum* (Leguminosæ) was first reported by Wunschendorff[1], who had subjected the defatted seeds to a process of extraction with alcohol. He obtained from the alcoholic extract a gelatinous precipitate which was afterwards dissolved in alcohol and reprecipitated with ether. Wunschendorff described the product so obtained as a white semi-crystalline powder, m.p. 214–215°, which gave a yellow colour test with concentrated sulphuric acid, and a white precipitate with barium hydroxide solution. However, he could not assign a definite formula to the saponin, but showed that it gives by hydrolysis a reducing sugar and water-insoluble sapogenin.

In view of the fact that very little is known of the chemical nature of the sapogenin, we have systematically investigated the seeds, and succeeded in isolating the sapogenin in a pure state. The powdered seeds of Trigonella were defatted by extraction with light petroleum, then extracted three times with alcohol. Concentration of the combined alcoholic extracts yielded a brownish syrup which dissolved freely in water, and the solution exhibited considerable frothing on shaking. A solution of the syrup in water was treated with a saturated solution of barium hydroxide; thus a saponin complex was obtained in the form of an orange amorphous precipitate. Further, the complex was suspended in alcohol and decomposed with carbon dioxide, then the alcoholic solution was concentrated to a faintly coloured syrupy solution. The latter solution was gradually poured into dry acetone; thus a white ashless powder was obtained. It melted between 190° and 200° (decomp.), and characterized by giving a white precipitate with barium hydroxide, a bluish precipitate with Fehling's solution, and a yellow colour with concentrated sulphuric acid. Hydrolysis of the saponin with hydrochloric acid gave a water-insoluble precipitate which crystallized from acetone in the form of a brownish semi-crystalline product. It was further purified by extraction (Soxhlet) with light petroleum, then crystallized from dioxan in white plates, m.p. 184°. The crystalline product gave the colour reactions of sapogenins, and appeared to be a mixture of sapogenins from which a pure compound, m.p. 198°, was isolated and assigned the formula $C_{27}H_{42}O_3$, comprising a free hydroxyl group and two inactive oxygen atoms. There is also evidence that it belongs to the sarsasapogenin group of sapogenins, and identity of its structure is now the subject of a detailed study.

Dynamics of Real Crystals

In his well-known theory of the specific heat of solids, Einstein made the fundamental assumption that all the atoms in a crystal are capable of vibrating independently of one another with the same frequency. It was not meant as an exact description: the intention was to get a sufficiently good approximation without unessential intricacies. His theory has been recalled here at the outset because we find that his approximation is only an extreme form of the hypothesis to be formulated at the end of this note.

In their theory of the vibrations of solids, Born and Kármán introduced the so-called "cyclic lattice hypothesis", which is the basis of the whole theory of crystal dynamics developed by Born and his collaborators. Sir C. V. Raman has recently questioned the correctness of the hypothesis and has suggested that it is dynamically unsound; it need scarcely be said that if the hypothesis is unjustified from the mathematical point of view it must be given up. Even if the exact theory of the lattice vibrations based on certain extreme idealizations be worked out, it will not serve to describe the vibrations of a real crystal unless it conforms to experiment. The exact and complete solution of the problem of the vibrations of a linear diatomic lattice under internal forces was obtained here some time last year, and has been given independently by Born. Born's work, however, contains some mathematical errors, for his enumeration does not include the obvious translation of the lattice as a whole, or that vibration which, when the number of atoms is only two, corresponds to their mutual vibration.

The cyclic lattice method originally proposed by Born affords the solution that the vibrations take place as those of the infinite lattice the wave-lengths of which are sub-multiples of the dimensions of the finite lattice. In his recent paper he appears to suggest that the cyclic lattice method is justified because the frequency-range given by it is the same as that given by the exact theory. This is not the point of dispute. What had to be shown is that there are vibrations of the finite lattice to which we can ascribe wave-lengths, and that they are of the order $L/N + o(1/N)$.

There are certain features of the cyclic lattice solution which are misleading, such as the degeneracy of over-vibration, and secondly, the existence of progressive wave solutions. It can be shown that over-vibration of a finite lattice is non-degeneracy, and progressive wave solutions are impossible. The exact theory shows that there will be the so-called optical and acoustic branches. However, for displacement (a) of the first atom, the maximum displacement of any atom will be $O(a)$ in acoustical vibrations, while the maximum amplitude will be $O(Na)$ in optical vibrations. The magnitude of the maximum amplitude falls off far more readily in the case of the optical branch than in the other. The important point is that whereas the acoustical vibrations depend on the nature of the boundary, it would require a very perfect crystal with perfect boundary conditions for all the atoms in an optical vibration to vibrate in the same phase, though not with the same amplitude. In the exact solution, infinitesimal displacements in not negligible regions have to form as nodal bridges. These considerations force us to draw a distinction between vibrations in perfect crystals and in real crystals.

The following is a working hypothesis to describe the vibrations taking place in a real crystal:

(1) There will be two types of vibrations, one of high frequency and the other of low frequency. These types must not be confused with the optical and acoustical branches introduced by Born.

(2) Almost all the vibrations will be of the high-frequency type, that is, the number of vibrations will be $O(3N)$.

(3) A high-frequency vibration can appear anywhere in the crystal, being limited only by a closed surface which we term the 'vibrational volume', outside which the disturbance caused will be negligible. The dimensions of the vibrational volume depend only on the nature of the crystal forces and crystalline symmetry, for the high-frequency spectrum will be a monochromatic one with a small number of frequencies.

These assumptions include Einstein's hypothesis in an extreme form when the vibrational volume is the atomic volume itself and over-vibration is a high-frequency one. The ideas contained in (2) and (4) have been stressed by Sir C. V. Raman in his publications.

In contrast with the difficulties of the idealized theories, and the lack of satisfactory correspondence with experimental results, the above hypothesis would seem to account for many of the results, especially the numerous Raman lines in crystals, the infra-red bands, the specific heat and the thermal conductivity of crystals.

Details of this work will appear elsewhere.

Density of Frequencies in Lattice Dynamics

THE preceding communication by Dr. Nagendra Nath is one of a series attempting to defend Raman's interpretation of the diffuse spots in X-ray photographs of crystals by discrediting the thermal theory accepted by other investigators of this phenomenon. Raman insists that not only is this application of lattice dynamics to X-ray scattering wrong, but also the foundations of lattice dynamics itself. He questions in particular the method of the 'cyclic boundary conditions', which consists in the following: The vibrations of a finite piece of the crystal depend in principle on the shape of the surface and the dynamical conditions prevailing on it. But if the dimensions of the piece are large compared with the single cell, it is plausible that the dependence on the boundary conditions will be inessential, so that these can be replaced by simpler ones (periodicity). The same assumption is made in the theory of radiant heat (black body radiation) and of the electrons in metals. It has never been doubted in these applications, and whoever rejects it would have to reconstruct these extended theories without this simplification.

In order to disprove Raman's objections directly, I have published the solution of a simple example, the finite diatomic chain (linear lattice), and shown that the quantity essential for the thermal applications, the density of the frequencies, is asymptotically the same for the rigorous and the cyclic solution. Dr. D. E. Rutherford, of the University of St. Andrews, who has checked my results by a different and ingenious method, has found that one of the frequencies given in my paper is incorrect; but this is, of course, quite insignificant for the problem considered, as a linear lattice of 1 cm. length has about 10^8 frequencies. In the preceding communication Dr. Nagendra Nath reports that he has worked out (but apparently not published) the same example and found the same mistake (he claims to have found another one, but this statement of his is incorrect). He has also confirmed the splitting of the frequencies into two branches; whether he has found the asymptotic density law is not evident from his letter, as he speaks only about the 'range of frequency', which is not relevant in this connexion.

Dr. Nagendra Nath's subsequent considerations are incomprehensible to me, as for example: "In the exact solution, infinitesimal displacements in not negligible regions have to form as nodal bridges", from which he infers that one has to consider 'real' instead of 'perfect' crystals. For this purpose he formulates four "working hypotheses" the meaning of which is hard to understand (even if a "monochromatic one [spectrum] with a small number of frequencies" is allowed for as a lapsus linguæ). There seems to be no more justification for these hypotheses in the extensive literature on 'real' crystals than in lattice dynamics.

To end this discussion about the cyclic condition, I have asked the help of a mathematical expert, Dr. W. Ledermann, of the University of St. Andrews. He has proved (see the following letter) a theorem which suffices for the foundation of all purely thermal applications of lattice dynamics (specific heat, thermal expansion, etc.) and in addition shows that a break in the regularity (missing or wrong atoms) at a number of places small compared with the total number of lattice points does not materially influence the thermodynamical results. This theorem may not be quite sufficient for all problems of crystal theory. The scattering of X-rays, however, which is the main object of Raman's attack, is quite independent of it. In a paper which will soon appear in *Proc. Roy. Soc.* I have shown that the formula for the diffuse thermal scattering can be derived in such a way that no other mathematics is used than in the Laue-Bragg theory of ordinary scattering, namely, the fact that certain lattice sums, which are simple generalizations of the Laue function $\sum_{n_1n_2n_3} \exp i(n_1x_1+n_2x_2+n_3x_3)$, are approximately independent of the boundary for large crystals.

MAX BORN.

Department of Mathematical Physics,
University, Edinburgh.

IN connexion with the asymptotic distribution of the eigen-frequencies of a cyclic and a finite lattice, the following mathematical theorem will be found helpful:

Let A be a real symmetric matrix of order n in which we display a 'core' C bordered by a single row and column, thus:

$$A = \begin{bmatrix} C & h \\ h' & \eta \end{bmatrix},$$

where C is a symmetric matrix of order $n-1$, h a column, h' its transpose and η a number. The latent roots of A are n real numbers $\mu_1, \mu_2, \ldots, \mu_n$. Let the number of latent roots which lie in the interval $\alpha \leqslant \mu \leqslant \beta$ be denoted by $P(\alpha,\beta)$. We wish to compare the latent roots of A with those of the matrix

$$B = \begin{bmatrix} C & k \\ k' & \varkappa \end{bmatrix},$$

which differs from A only in the last row and column. If the number of latent roots of B in the same interval be denoted by $Q(\alpha,\beta)$, it can be shown that

$$|P(\alpha,\beta) - Q(\alpha,\beta)| \leqslant 2.$$

This inequality is independent of the particular border (h,η) or $(k,\varkappa)$ and is independent of n. The result is especially interesting for large values of n, as it provides a proof of the plausible fact that the distribution of the latent roots of a *large* symmetric matrix is not materially changed by the modification of the last row and column. When the last p rows and columns are modified, the inequality reads

$$| P(\alpha,\beta) - Q(\alpha,\beta) | \leqslant 2p.$$

Hence if p be small compared with P or Q, it follows that P and Q are asymptotically equal.

The bearing of this theorem on the problem of crystal vibration is as follows: the N atoms of the lattice are divided into internal atoms and boundary atoms, according as the atom has a complete set of *acting* neighbours or not. Instead of numbering the atoms with three indices corresponding to their spatial arrangement (as is usual in lattice theory) we imagine the atoms to be enumerated in a simple sequence, starting somewhere in the interior and taking first all the internal atoms and then adding the boundary atoms. As the vibration is vectorial, there are three equations of motion for each particle. The number, p say, of 'boundary' equations is of smaller order of magnitude than that of the 'internal' equations ($p \sim N^{2/3}$). The matrix whose latent roots are the squares of the frequencies is of the type A considered above, involving a border of p rows and columns. The introduction of the cyclic condition causes a change only in the border elements of the matrix, and the theorem regarding the asymptotic density of the latent roots can be applied; that is, this density is practically the same as that for the cyclic lattice.

The application of the method to the case of defects of the lattice (missing or wrong atoms) is obvious.

Classification of Rheological Properties

I HAVE been interested by recent reports in NATURE, by the British Rheologists Club, relating to the classification of rheological properties. Since suggestions have been invited for improving the table of deformation, I put forward the following for consideration.

I believe that the table in NATURE of June 20, 1942 (p. 702), already an improved form of the earlier table shown in NATURE of February 14 (p. 197), can be made still clearer if the heading "Flow" is omitted and the first division made a three-fold one into "Elastic", "Plastic", and "Viscous". It may be natural to classify bodies according as they flow or do not flow under stress, but I suggest that this is as arbitrary a classification, scientifically, as some that have been adopted in other parts of the system, its main virtue being that it is based on phenomena readily appreciated by the non-scientific mind.

Further, the groups "Elastic" and "Plastic" overlap at the lower end of the table, and the groups "Elastic" and "Viscous" also overlap, whereas "Plastic" and "Viscous" remain distinct, although these actually have a common heading in the present table. This seems to me a little illogical.

If this step is allowed, then by setting out the three main headings with "Elastic" placed centrally, we can construct the table with less interference of the lines, and keep the three main groups separated. The balance of the table is also preserved. The accompanying diagram shows the arrangement that I propose.

I do not, of course, claim that I am making any addition to the system of rheological classification, but I think that it will be agreed that the proposed rearrangement has some points in its favour.

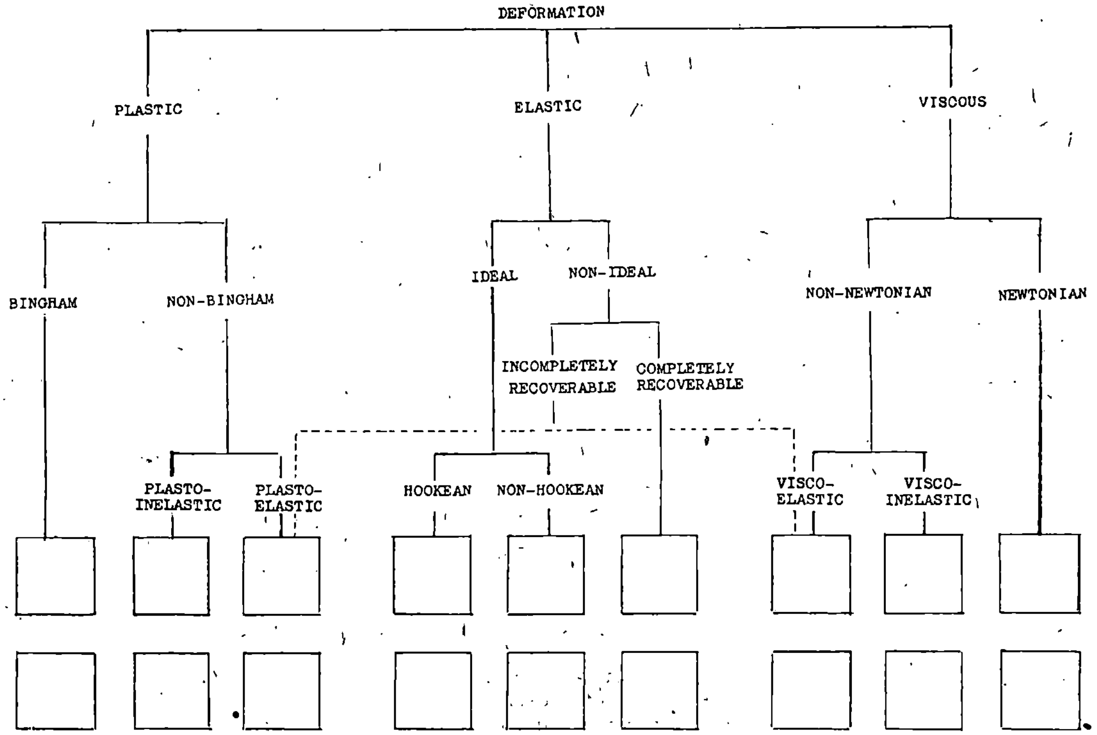
Detection of Acid or Basic Substances in Damaged Fabrics

Feigl and Da Silva[1] have put forward methods for detecting basic and acid substances when present in many materials normally regarded as insoluble, when acidity or basicity cannot be detected in the normal manner, for example, by a pH determination.

We wish to direct attention to a possible use of these methods in the examination of faults in textile materials. It has long been known that acid or basic substances often damage textile fibres, but whereas certain methods of detection are available, there is plenty of room for a quick and reliable method. Feigl and Da Silva's work seems to make this possible.

If a solution of a nickel salt is incompletely precipitated with dimethyl glyoxime and filtered, one obtains a solution which on application to a fabric damaged by alkali (for example, caustic soda) causes the damaged fibres to take on a pink colour which is easily visible. This test has been tried with cotton and woollen fabrics.

Similarly, a saturated solution of silver chromate in ammonia ($6N$), when applied to fabrics damaged by acids, shows a dark red-brown colour. This test did not work so well with damage by hydrochloric



acid on cotton; wool damaged by this acid gives a white spot inside a dark ring.

With coloured materials, while the coloured precipitate is not so noticeable to the naked eye, we have found it easily visible under the microscope even when the fabric and precipitate are the same colour.

Further investigations are in progress with the view of extending the scope of these tests.

Soil Conditions Affecting Production of Perithecia in Banana Leaf Spot Disease

RECENT research[1] has brought to light the existence of the ascigerous stage (*Mycosphærella musicola*) of the fungus *Cercospora musæ*, during studies on the etiology of leaf spot or 'Sigatoka' disease of bananas. Perithecial formation is mainly seasonal, being greatest between August and January.

Experiments have shown that three-weekly spraying cycles, for example, with 4-4-40 Bordeaux mixture, are unable to control banana leaf spot satisfactorily unless the disease is brought under control before the start of the ascospore season. This applies to almost the whole of the banana-growing districts in Jamaica.

In a few isolated areas, however, it has been found that perithecia are produced in profusion throughout the year. A recent survey of these areas has shown that this 'out-of-season' production of perithecia is positively correlated with the growth of banana plants on highly acid soils (pH 4·0–4·75 approximately). Regular three-weekly spraying has likewise failed to give satisfactory control of the disease at any time throughout the year. Only by employing the weekly heart-leaf spraying method[2] has control been obtained. This method is impracticable once the plants have grown tall; unless liming or some other means can be found to ameliorate the effect of high soil acidity on the metabolism of the Gros Michel banana and its parasite (*M. musicola*), spraying will prove useless as an economic measure of controlling this leaf spot disease under these conditions.

No experimental data are at present available to explain this physiological problem. It is possible that the water relationship of the soil may also be found to play a part in this abnormal production of perithecia. A search through available literature has failed to disclose a similar example of soil conditions affecting the fructifications of a leaf spot fungus.

Rumford's Contributions to Nutrition

THE instructive note on Charles Darwin's health by Sir Buckston Browne in NATURE of January 2, p. 14, lends interest and certainly gives point to the forthright opinions expressed by Count Rumford about ". . . that most pernicious wash, *tea*, with which . . . the inhabitants of this island drench their stomachs, and ruin their constitutions".

"When tea is mixed with a sufficient quantity of sugar and good cream," he wrote; "when it is taken with a large quantity of bread and butter, or with toast and boiled eggs; and, above all, *when it is not drunk too hot*, it is certainly less unwholesome; but a simple infusion of this drug, drunk boiling hot, . . . is certainly a poison which, though it is sometimes slow in its operation, never fails to produce very fatal effects, even in the strongest constitution, where the free use of it is continued for a considerable length of time."

When, some years ago[1], attention was invited to Rumford's contribution to the science of nutrition, the substitution of potatoes for bread had not the importance which it has now and which it had in Rumford's day. Rumford gives many interesting recipes and records that so strong was the aversion of the (Bavarian) public to potatoes that for a time he found it necessary to disguise them by boiling them down entirely to destroy their form and texture and so prevent them being detected. This is how he made *calecannon*, an Irish dish: potatoes 19 cwt., greens 295½ lb., butter 98 lb., onions 14 lb., salt 40 lb., black pepper 1 lb., ginger ½ lb. 273 gallons of pump water were brought to the boil; the greens were added, and fifteen minutes after they had come to the boil they were taken out and replaced by the potatoes, which were cooked in the same way. The potatoes being mashed (without peeling them), and the greens chopped fine with a sharp shovel, they were mixed together. The other ingredients were added, the whole was well mixed and it was served in wooden noggins to 927 persons. It would be scarcely possible, Rumford remarks, to invent a more nourishing or more palatable kind of food than calecannon; and with this kind of food there is no allowance of bread, nor is any necessary.

Rumford's advice on how to dress salt-fish to perfection has likewise an added interest at the present time: "the secret of cooking it is to keep it a great many hours in water that is *just scalding hot*, but which is never made actually to boil".

Sir Henry Miers

EXCEPT in popular estimation, no man's reputation really rests upon a single discovery, and whether Ramsay or Rayleigh discovered argon, or whether Ramsay, Hillebrand or Miers discovered helium, are really questions involving the definition of the word 'discovered', and, as Mr. Humberstone has found[1], of little or no interest to those most particularly concerned.

However, the circumstances surrounding those discoveries are of real interest, and may be made living stories through the correspondence which passed between those who participated in them. I have in safe keeping the letters which passed between Ramsay and Miers and a mass of papers and correspondence belonging to Ramsay, which were left by Lady Ramsay. I hope to publish them after the War.

MORRIS W. TRAVERS.

FORMATION OF PLANETARY SYSTEMS

A CONSIDERABLE amount of interest has been shown in recent times on the subject of the origin of planets and satellites, and various theories have been developed with the primary object of circumventing the angular momentum difficulty. A recent paper by B. M. Peek, entitled "The Formation of Planetary Systems" (*J. Brit. Astro. Assoc.*, **53**, 1; December, 1942), puts forward a theory which possesses at least the merits of simplicity. He starts off with a quotation from Sir James Jeans's "Astronomy and Cosmogony" (1928), which attempts to explain the angular momentum of the nebulæ: "Any currents or motion in the original medium would contribute angular momentum to the nascent nebulæ, and as these shrank to nebular dimensions, the constancy of angular momentum would result in fairly rapid rotations of the shrunken masses". Peek extends this view to the next order of condensation—the stars—and is thus able to explain how the necessary angular momentum of the solar system, and other possible planetary systems too, can be accounted for.

Starting with a portion of the galaxy having a nearly uniform distribution of matter, Peek postulates the beginning of the gravitational instability which produces *stars*, and further postulates that the random currents in the medium contribute angular momentum to these nascent *stars*. After a time any diffuse star rotating about an axis which is perpendicular to its equatorial or invariable plane will have most of its angular momentum concentrated close to the rim of this plane. The system has no resemblance to Laplace's nebula, which was supposed to rotate almost like a rigid body. For this reason the main bulk of the star will be almost spherical, not lenticular, as contraction proceeds. In time, however, the small portion of matter at the rim, which received its momentum from the original current, will have communicated some of its motion to other portions in the immediate vicinity, owing to viscosity. The shrinking of the star is necessarily accompanied by an increased angular velocity, in order that the angular momentum may be preserved, and finally portions of matter will be expelled from the periphery and will describe orbits about the still shrinking star. Some quantitative results are given, among which reference may be made to one in particular. Peek has calculated that if the original current had the same order of mass as all the planets combined and moved with a velocity of two metres per second, this current would have been able to endow the whole of the solar system with its observed angular momentum.

By the time all the matter had been shed, a small fraction of the angular momentum would have been communicated to the condensing nucleus, and this may be the explanation of the rotation of the sun in a plane which does not differ very much from the invariable plane. It is suggested that after the main nebula collapsed into discrete condensations, stray wisps of the material composing the nebula, possessing random velocities, would hang about in conditions of unstable equilibrium between the stars in process of formation, and would finally be captured by one or the other of these. Here is a tentative explanation of the origin of the long-period comets. The theory is also able to explain the origin of the satellites and especially their direct motion, but it is admitted that retrograde satellites and also a system like that of Uranus present difficulties. Periodic comets may have been formed from matter left over from the planetary condensations.

No detailed explanation is attempted regarding the manner in which matter would be shed from the contracting mass, though certain possibilities are suggested. This particular part of the subject involves very abstruse mathematics dealing with gas-kinetics, and it is to be hoped that this branch will be developed further. It is conceivable that the theory may encounter some of its greatest difficulties here.

HEALTH IN INDUSTRY

THE importance of securing, in the crisis of man-power and woman-power through which Great Britain is now passing, that there is no waste of labour and that the full woman-power and man-power of the country is utilized to the maximum extent possible in furtherance of the nation's war effort—though it should be noted that the latter is not to be interpreted too narrowly—is now generally appreciated. As the last report of the Chief Inspector of Factories showed, the importance of eliminating the loss of man-hours and woman-hours due to accidents and to sickness is still far from being realized. Nor, as that report and successive reports of the Select Committee on National Expenditure have indicated, have managements either in industry or in Government departments and factories learnt the lessons and applied to good purpose the experience acquired during the War of 1914–18.

That truth is well emphasized in the third report of the 1942–43 session from the Select Committee on National Expenditure. Here the results of the investigations of the Committee on the health and welfare of women in war factories are detailed, and the observation recorded at the outset that little attention seems to have been paid to many of the constructive suggestions contained in earlier reports on health and welfare problems would justify this further inquiry. The relation of health to production is indeed one of the widest interest, as well as of growing importance as the demands of the War grow more imperative. It involves the co-operation of the worker as well as of factory management and of the Government.

Broadly speaking, an efficient general state of health in industry depends on the improvement and maintenance of what is commonly called physical fitness; the prevention of diseases and of accidents; the treatment of sick and injured persons and their rehabilitation to fit them for return to industry. The problem to-day is largely one of the most economical use of women, particularly in view of the breakdown of any system of medical examination as to the fitness of women for factory work before they are transferred to work away from home.

The results of this inquiry are set forth in three main divisions: health and welfare within the factory, and, secondly, outside the factory; and the State and industrial health. In regard to the first, matters relating to the maintenance of health can be grouped under three general headings: (*a*) physical amenities, such as the provision of satisfactory canteens, cloak-rooms, rest-rooms, etc.; (*b*) medical provisions, such as first-aid, preventive measures for specific industrial diseases, and the general medical supervision of the life of the factory; and (c) general oversight, such as the administrative and executive action which has to be undertaken by welfare or personnel officers. While the general level of physical amenities is on the whole satisfactory and in many factories the standard reached is high, the Committee raises a number of matters in relation to canteens, including inadequate time for meals, and to cleanliness and rest-rooms, which should be brought to notice.

It is recommended next that the Government should give the closest attention to the problem of securing a satisfactory industrial medical service, at least within all the factories engaged on Government work. In this connexion the Committee considers that greater use could be made of women medical practitioners and recommends further that consideration should be given to the question of establishing a centralized employment register for trained nurses. Once again the recommendations that further energetic measures to improve the general standard of lighting in the medium-sized and small factories should be taken by the Ministry of Labour and the supply departments concerned, and that the provision of adequate ventilation in royal ordnance filling factories should be dealt with as a matter of urgency indicate how far we are even yet from harnessing to the service of our war effort even existing scientific knowledge.

Other recommendations in this field are that the supply departments should assist contracting firms to introduce black-out arrangements that will allow of the entrance of a reasonable amount of daylight to workshops, canteens and rest-rooms, and that when new Government factories are in course of construction, or are to be built in the future, expert advice and co-operation should be sought at the earliest stage to ensure that adequate systems of lighting and ventilation are adopted. Further evidence confirms the comments of the Chief Inspector of Factories as to the frequent neglect to take the elementary precaution of training new workers in the use of safety devices, and in regard to hours of work further research and experiment are recommended to determine the best method of arranging a rotation of shifts in royal ordnance factories so as to reduce fatigue and to ensure a minimum of inconvenience to workers and managements. The Committee suggests further that, where a two-shift week is worked, it would be advantageous for departments to organize a five-day week for their women employees.

Once again the crucial importance of personnel management is stressed. The Appointments Board of the Ministry of Labour should carefully consider whether more use could not be made of older men and women with a good educational background as labour officers in factories, and the Select Committee recommends further that the Ministry of Aircraft Production should co-operate with the Ministry of Labour in organizing courses for training personnel managers and welfare workers for firms in the aircraft industry, to which the existing staff in aircraft firms might be sent for refresher courses. It is somewhat disturbing to find that there is still neglect of personnel organization in the aircraft industry, and the Committee also comments on some lack of co-operation between the production staff, labour management and the medical officers in the royal ordnance factories. Examination by the Ministry of Labour of the existing machinery for transferring workers from one district to another with the view of securing a closer relation between regions that are exporting labour and those that are receiving it, so as to ensure that factories are notified of the arrival of new workers in sufficient time to enable the necessary arrangements to be made for their reception, is also recommended, as well as a review of the subject of wartime nurseries.

The latter question falls into the section of the report dealing with health and welfare outside the factory. Here stress is laid on shopping difficulties, which are still acute for most women-workers in many areas, and on the provision of billets, to which a like remark applies. Here the Committee suggests that the regional and local welfare officers of the Ministry of Labour might impress on the more backward firms the advantage to be gained by making better provision for the welfare of workers outside the factory, such as the development of social centres or clubs, and the installation of shower-baths for those unable to obtain baths.

The section of the report which deals with the State and industrial health is of major interest to scientific workers. Discussing first the allocation of responsibilities, the Committee agrees with the broad division of functions between the Ministry of Labour and the supply departments, which should carry a joint responsibility for the maintenance of good personnel management. It is recommended that the factory inspectorate should be relieved of any tasks that can be transferred elsewhere without loss of efficiency, so that the inspectorate may be free to concentrate on the maintenance of good standards of safety and health. It is pointed out, however, that co-operation between the inspectorate and those responsible for the royal ordnance factories has not been as full as it might be. The constitutional relationship is not altogether easy, and the medical branch of the factory inspectorate from its composition has neither a staff sufficient to provide advice and instruction on a wide scale nor the authority to ensure that the advice it is able to proffer is accepted by those who need it most. Again, while the Ministry of Labour's welfare officers have done much useful work in securing the provision of facilities for the health and welfare of workers outside the factory, difficulty has been experienced in obtaining suitable people for this advisory work by local recruitment, and the Select Committee recommends that the Ministry of Labour should take immediate steps to recruit older women with the right type of experience.

Neither the Ministry of Supply nor the Ministry of Aircraft Production has, in the Committee's opinion, given the attention to the problems of industrial health and welfare in contractor's factories that is desirable, and the Committee recommends the appointment of medical women as additional advisers to both Ministries. The report once again notes the failure of the supply departments to utilize fully the special knowledge of the Industrial Health Research Board, and while expressing the hope that the fullest use will be made of the results of the work now being undertaken, stresses the need also for comprehensive planning.

To meet this need and to place the existing organization for creating and maintaining the standards of industrial health on a surer foundation, the report finally recommends a rearrangement of the medical supervision of industrial health. First, the medical branch of the factory inspectorate should be enlarged and strengthened. Secondly, a central industrial health advisory committee should be set up forthwith to advise the Ministry of Labour and the supply departments on all questions of industrial health and on the co-ordination of medical services to meet the requirements of the war effort. Regional industrial health advisory committees should also be set up to advise the Ministry of Labour, the regional boards and employers on the co-ordination and extension of industrial health centres in each region. A central bureau should be established for collecting, abstracting and disseminating information and literature relating to all questions of industrial medicine. The need for this is particularly stressed, including the publication of a bulletin, and the bureau might be modelled on similar organizations existing in other fields of applied science. Working in close association with the British Medical Association, the Medical Research Council (particularly the Industrial Health Research Board), and the Association of Industrial Medical Officers, and with an enlarged and strengthened organization of medical inspectors of factories, these committees should do much to reduce the incidence both of industrial disease and of general sickness among industrial workers and others, and thus materially increase the volume of output with a corresponding reduction in cost to the nation.

FORTHCOMING EVENTS

(Meeting marked with an asterisk is open to the public)

Saturday, February 13

Iron and Steel Institute (joint meeting with the Sheffield Metallurgical Association, the Sheffield Society of Engineers and Metallurgists, and the South Yorkshire Section of the Institute of Chemistry) (at the Royal Victoria Station Hotel, Sheffield), at 2.30 p.m.—Mr. H. T. Shirley and Mr. E. Elliott: "A Critical Consideration of some Applications of the Spectrograph to Steelworks Analysis".

North-East Coast Institution of Engineers and Shipbuilders (at Bolbec Hall, Newcastle-upon-Tyne), at 6 p.m.—Dr. W. D. Jones: "Powder Metallurgy, its Products and their Various Applications".

Association of Scientific Workers (Harpenden Branch) (at the Congregational Hall, Harpenden, Herts.), at 5 p.m.—Mr. F. Le Gros Clark: "Agriculture in relation to Food Policy".

Monday, February 15

Royal Geographical Society (at Kensington Gore, London, S.W.7), at 8 p.m.—Dr. Kaare Rodahl: "The Swedish-Norwegian Expedition to North-East Greenland, 1939–1940".

Tuesday, February 16

Royal Society of Arts (Dominions and Colonies Section) (at John Adam Street, Adelphi, London, W.C.2), at 1.45 p.m.—Dr. S. S. Pickles: "Rubber, Natural versus Synthetic".

Society of Chemical Industry (joint meeting of the Agriculture Group and the London Section) (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 2.30 p.m.—Prof. G. W. Robinson: "Methods and Interpretation of Soil Analysis".

Royal Institution (at 21 Albemarle Street, London, W.1), at 3 p.m.—Sir Lawrence Bragg, F.R.S.: "The Solid State" (iv) "Plus-plus Compounds".*

Institution of Electrical Engineers (Wireless Section) (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Discussion on "Electronics in Industry" (to be opened by Mr. E. Cattanes, Mr. G. T. Winch and Mr. A. L. Whiteley).

Wednesday, February 17

Royal Society of Arts (at John Adam Street, Adelphi, London, W.C.2), at 1.45 p.m.—Dr. C. H. Desch, F.R.S.: "Magnesium" (Peter le Neve Foster Lecture).

Royal Meteorological Society (at 47 Cromwell Road, South Kensington, London, S.W.7), at 4.30 p.m.—Major H. C. Gunton: "Report on the Phenological Observations in the British Isles from December 1941 to November 1942".

Institute of Physics (at the Royal Institution, Albemarle Street, Piccadilly, London, W.1), at 6 p.m.—Annual General Meeting. Dr. J. R. Baker: "Freedom in Science".

Thursday, February 18

Chemical Society (at Burlington House, Piccadilly, London, W.1), at 2.30 p.m.—Prof. J. M. Gulland: "Aspects of Nucleotide Chemistry" (Tilden Lecture).

Pharmaceutical Society (at 17 Bloomsbury Square, London, W.C.1), at 7 p.m.—Charter Centenary Meeting and Address by the President, Mr. W. Spencer Howells.

Friday, February 19

Royal Institution (at 21 Albemarle Street, London, W.1), at 5 p.m.—Prof. E. J. Salisbury, F.R.S.: "The Flora of Bombed Areas".

Institution of Mechanical Engineers (at Storey's Gate, St. James's Park, London, S.W.1), at 5.30 p.m.—Annual General Meeting. Mr. K. S. Laurie: "Some Textile Finishing Machines".

APPOINTMENTS VACANT

Applications are invited for the following appointments on o before the dates mentioned:

Teacher of Mathematics and Science at the East Ham Technica College—The Secretary for Education, Education Office, Town Hal Annexe, Barking Road, East Ham, London, E.6 (February 19).

Laboratory Steward in the Department of Physiology—Th Secretary and Registrar, The University, Bristol (February 20).

Psychologist for the Derby Child Guidance Clinic—The Actin Director of Education, Becket Street, Derby (February 22).

Two Senior Technical Assistants—The Executive Officer, Eas Riding of Yorkshire War Agricultural Executive Committee, St Mary's Manor, Beverley, Yorks. (February 22).

Director of the Gas Research Board of the Gas Industry—The Secretary, Gas Research Board, Gas Industry House, 1 Grosveno Place, London, S.W.1 (February 22).

Lecturer in Mechanical Engineering, and an Assistan Lecturer in Mechanical Engineering—The Registrar, College o Technology, Manchester 1 (March 1).

Master to teach Mathematics and Science at the Bingle Technical School—The Divisional Educational Officer, Educatio Offices, Bingley, Yorks. (March 7).

Chair of Chemistry in the University College of North Wales—The Bursar and Acting Registrar, University College of North Wales Bangor (April 3).

Assistant Lecturer, mainly for Science, Mathematics an Drawing—The Principal, County Technical School, Halesowen Worcs.

Teacher of Engineering Workshop Practice and Genera Engineering Subjects at the Burton-on-Trent Technical Institut and Junior Technical School—The Secretary and Director of Education, Education Offices, Guild Street, Burton-on-Trent.

Speech Therapist—The Education Officer, County Hall, Wakefield

Part-time Demonstrator in the Physics Department—Prof H. Dingle, Imperial College of Science and Technology, South Kensington, London, S.W.7.

Laboratory Assistant for School Laboratory—The Senio Science Master, The Science Schools, Harrow School, Harrow, Middx

SCIENTIFIC RESEARCH AND DEVELOPMENT

Research in War-time

THE satisfaction which was felt at the time when the Government announced on September 4 the appointment of three scientific advisers to the Ministry of Production, to complete the organization for scientific research and development, has been somewhat diminished by subsequent changes in the Government itself. The appointments did not, it is true, meet all the criticism that had been advanced of the organization of the scientific resources of Great Britain in furtherance of the war effort, and in particular the demand for the establishment of a whole-time Central Scientific and Technical Board. Further, it was recognized that the success of the new arrangements, including the appointment of Sir Charles Darwin as scientific adviser to the Army Council, depended largely on the right men being chosen to fill the new posts, as well as on the spirit in which the Ministries and Departments would co-operate, as was pointed out by the Select Committee on National Expenditure. None the less, there was a general feeling that the new organization should be given a fair trial before criticizing it too severely.

One of the reasons for welcoming the appointment of the three full-time scientific advisers to the Minister of Production was the statement that they would work under the immediate supervision of the Lord Privy Seal (then Sir Stafford Cripps), acting on behalf of the Minister. With Sir Stafford's appointment as Minister of Aircraft Production, he has now to carry the responsibilities of the administration of a department of crucial importance, and he has also been invested with special responsibilities in regard to the anti-U-boat campaign which must make further large demands on his time. Not only is it therefore unlikely that he will be able to devote the detailed attention to the activities of the new scientific advisers which was expected, but also, since he is no longer a member of the War Cabinet, he can scarcely represent their views to those who are directing the War, at any rate so effectively as scientific workers expected in welcoming the appointments.

For these reasons Sir Stafford Cripps's paper on "Government and Science in Great Britain" at the opening session of the recent conference of the Association of Scientific Workers on "Planning of Science: in War and in Peace" (see NATURE, February 6, p. 152) was awaited with unusual interest. Sir Stafford Cripps's statement, however, proved somewhat disappointing and in general added little to the statements which we have already had on various occasions from Lord Hankey and Lord Chatfield, with which it can fairly be compared. At many levels there is, as Sir Stafford Cripps was able to show, close collaboration, but he admitted that in regard to industrial research there is still room for better integration of research and development with the supply ministries.

Sir Stafford Cripps's statement does suggest, indeed, that we are much nearer securing that the immediate study of strategy and tactics by the General Staff is conducted with an awareness of the possibilities which technical and scientific advance has put in our hands. Nothing in his address, however, goes far to resolve the doubts as to whether we can safely rely on advisory bodies for this purpose, or whether it is necessary that there should be some Central Scientific and Technical Board with executive, rather than advisory, powers. The failure to realize sufficiently early the vital part which science would play in this War, to which Sir Stafford Cripps alluded, is indeed an important consideration which might favour an executive body. Moreover, it has to be remembered that the time factor, which Sir Stafford gives as one reason for not creating a "tidy plan" of scientific organization of the war effort, may be an equally decisive reason in favour of a central scientific body with executive rather than advisory powers. Only so may it be possible on occasion to cut out departmental delays and bring down the interval between discovery and production to months or even weeks, as against the normal lag of years in peacetime.

The proposals advanced by Mr. E. D. Swann on behalf of the executive of the Association of Scientific Workers at the conference stress this vital factor of time and the importance of ensuring that the limited resources of Great Britain are fully used on the most vital problems. They provide for the establishment of a Central Scientific and Technical Board with scientific and technical qualifications and wide executive powers. This Board would be in direct contact with the War Cabinet, which it would advise on scientific matters. It would relate the country's scientific effort to the strategy determined by the War Cabinet.

It cannot be said that Sir Stafford Cripps, any more than Mr. Lyttelton, has shown that such central direction is unnecessary. Admittedly we are still paying the price for our long-continued national neglect of science, with the result that throughout the Fighting Services and in the Civil Service there are far too few in positions of high responsibility competent to assess the scientific and technical factors involved in the day-to-day tactical and strategical problems of the War. Scientific workers are not, of course, in supporting such proposals, advancing the claim to determine policy, though the extent to which policy must be based on scientific and technical considerations tends to increase rather than otherwise. It is, however, their moral responsibility to see to it by all means in their power that those responsible for the formulation of policy give full weight to the scientific and technical factors involved. More they cannot ask ; and to ask for less is a dereliction of duty.

On the whole, it may well be held that the balance of evidence points to some Board possessing executive authority, such as that suggested by the Association, the Parliamentary and Scientific Committee and other bodies, to supplement the work already being done by the Scientific Advisory Committee, the scientific advisers to the Minister of Production, the Engineering Advisory Committee and the numerous other committees, to the activities of which Si Stafford Cripps referred. At the same time it shoul be recognized that the personnel of such a board apart from its status, may well present greate difficulties than at first appear, and that much spad work will be required to ensure that it can functio harmoniously and effectively in its numerous depart mental relations.

There are two further points, however, whic should be noted. In the first place, while Air Chie Marshal Sir Philip Joubert de la Ferte's polite version of the dicta that the expert should be kep on tap, not on top, cannot be gainsaid, there is thi much to be observed. Sir Philip rightly said tha from the military point of view the ideal is for th Services to state the need and to put the requirement to the scientific man for investigation, but that at n time should the latter exercise judgment over militar matters. The real point at issue is this ability of th Fighting Services to formulate their requirements i time, simply because that can now only be done wit difficulty, or not at all, by those without sufficien first-hand knowledge of science to be aware at leas to some extent of the general trend of scientifi advance and its technical possibilities. Without tha background, the right questions and problems ma not be put to the scientific worker, or, if put, ma be put too late. It seems clear that Sir Philip Jouber himself appreciates this weakness, for he admitte that the division of functions is not always clear cut and that scientific men might be required to elucidat the position by advising on the need itself, as well a the requirements.

The second point relates to British contact wit the United States, to which Sir Alfred Egerton' address was devoted. It cannot well be maintaine that there is even yet a properly organized centr agency for bringing together the work of all th missions to the United States. Even if it possesse no executive authority, a Central Technical an Scientific Board should be able to establish a centr information bureau from which scientific and technical liaison could be conducted, so as to ensure tha departmental missions are at least in touch with on another, and that those at the centre know what al and not just a few, of the departments are doing.

The three charts reproduced on pp. 206–207, whic are based on diagrams prepared for the Conferenc illustrate the war-time organization of scientific effo in Great Britain, the United States and the U.S.S.

Research in Peace-time

This Conference of the Association of Scientif Workers, however, was summoned to consider th planning of science in peace as well as in war. S Stafford Cripps did well to remind us that there is i reality no difference in the principles that should b applied in time of war and in time of peace. It shoul also be remembered, however, that to ensure th speedy winning of the war, it may be necessary t adopt measures, in view of our long neglect of scienc as a nation, which should have no place in the pe manent organization when the appropriate steps t repair that neglect have been taken and had effect. The question whether the present organization and utilization of science in Great Britain are adequate to the service of national needs should not be determined solely by reference to war-time conditions. The principles on which that organization is based should be scrutinized in relation to long-term needs and tendencies, and not merely the pragmatism of war.

There is no need here to open a fresh discussion as to whether or not science should be planned. We cannot escape the necessity of planning, broadly, our scientific activities, along with other activities, if we are to ensure a society in which orderly development is possible and the opportunities which scientific advance has given us are to be enjoyed by the many and not by the few. It is not a question of planning or of not planning, but of the extent to which we shall plan, and the limits which are placed on our planning by the necessity for preserving a free society and the freedom of investigation and utterance essential to scientific advance. It is a question of so ordering society as to secure the best conditions for encouraging the highest quality of scientific and of other creative work.

Once this is clearly recognized, the controversy between the planners and those who oppose all planning as inconsistent with the freedom of science is seen to be irrelevant. Freedom for scientific inquiry, as Prof. H. Levy remarked, may be a catchphrase that confuses the issue and may obstruct advance, even if it does not play into the hands of reactionary movements. Freedom comes by recognizing and overcoming restrictions, not by ignoring them, and scientific workers may well ponder carefully a suggestive passage in Prof. E. H. Barker's great book, "Reflections on Government", in which he discusses, first, the process of democracy itself as an example of the scientific method, and then the authority of natural science and the place of the scientific expert.

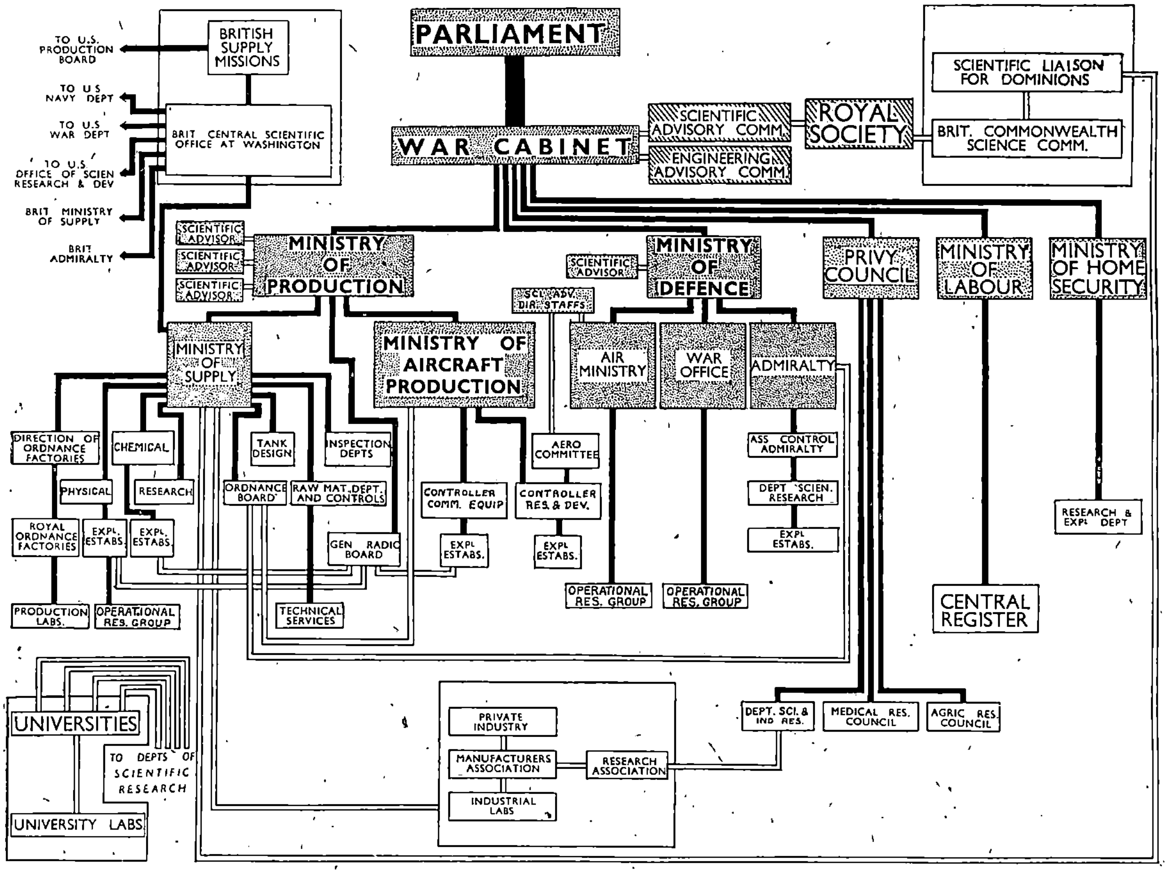
The effective prosecution of any adequate reconstruction policy will call for a much more effective utilization of science than in the past, but this emphatically does not mean the regimentation of science. It must involve, however, not simply the allocation of greater resources of material and man-power to scientific and to technical research as well as to training in science, but also to some extent the distribution of those resources where they are most needed in the interests of the community as a whole. It is not only in time of war that advance has been retarded and the solution of problems delayed because of the uneven front of research, and excessive concentration of man-power and resources on particular and even narrow fields. The problem is one of securing a reasonable balance between the different fields of knowledge, not of dictating the problems to which attention shall be given within particular branches of science; effort must be diverted from time to time to fields which from one cause or another appear to have been neglected, whether through special difficulties or the absence of sufficient incentive in comparison with others. It is no interference with the true freedom of science, for example, for the Government, in greatly extending its encouragement and support of long-range or fundamental research at the universities, to which we look for creative discoveries, to ear-mark its endowments for particular broad fields as, for example, agricultural biology, which have been comparatively neglected in contrast with the related field of nutrition. There must be some means of redressing the balance if society is not to suffer continually from the absence of scientific knowledge at some point which has not been sufficiently attractive to engage the attention of individuals.

It is equally true that there must be some satisfactory relation and balance between such academic research at the universities and that proceeding in industry and in Government departments. No policy of expansion of industrial research or research in Government institutions could be fruitful in the long run if long-range and fundamental research in the universities were starved. Further, both industrial research and research by Government departments are required to apply, for the benefit of the community, the advances in knowledge which come from the universities, apart altogether from the contributions in technique and the stimulation to thought which so often results from contact between workers in the universities and in industry or Government departments. An important aspect of the planning of science is indeed to foster such contacts and the frequent exchange of staff as well as of information. There could be no surer way of developing mutual respect between academic and industrial workers and breaking down misunderstanding and ill-feeling.

Some of the problems in this respect are admirably set forth in the paper which Mr. R. S. Bickle contributed to the discussion on planning after the War. The broad problems of scientific personnel were discussed by Sir Lawrence Bragg, who urged the importance of starting now to plan the university courses and facilities for research which would be required and clarifying ideas as to the existing institutions which could be used as nuclei for concrete proposals. In regard to personnel, he believes that the Central Register is the right body to watch conditions and to find the men, and that it will be essential to continue it for some years after the War. If the support and advice of the general body of scientific men be given to it, it would solve many problems of post-war placement, of assessing needs, and of regulating conditions. The problem of making use of scientific assets in planning the reconstruction of Great Britain is, he thinks, one of the most difficult of the post-war problems. It involves bringing home to political leaders and Civil Servants the place of science in the new world, bringing them into personal contact with the great leaders of science and firing their imagination with the possibilities of scientific achievement. Without this process of education, we cannot hope to devise the permanent machinery and organization for ensuring the wisest use of scientific and technical resources and the encouragement of fundamental research over the whole front of science.

How wide is the range of problems was well shown in Prof. P. M. S. Blackett's paper. Besides the re-education of a large number of younger scientific men and the re-building of fundamental research in the universities and research institutes, including the technical re-equipment of university research laboratories, there are such problems as the future scope and status of the expanded Government research establishments, and the encouragement of close relations between such laboratories, industrial research laboratories and the universities, and the place of the scientific societies in this relationship. Then there is the opening up of scientific relations with other countries and the organization of scientific assistance to liberated countries to help them restart their scientific life.

ORGANISATION OF SCIENCE IN THE U.K.



There can be no doubt as to the demands which such problems will make on scientific workers, and the attendance at the conference arranged by the Association of Scientific Workers, was welcome evidence that the younger men of science recognize their responsibility towards society as a whole. The effective utilization of science in the war effort and in reconstruction depends not only on the scientific man himself but also on the co-operation of management and workers as well. There has been persistent criticism of shortcomings in production in the reports of the Select Committee on National Expenditure, the Industrial Health Research Board and the Chief Inspector of Factories, of the failure of management to make full use of scientific knowledge which has long been available, in such matters as welfare, lighting, hours of work, safety and the like. If some of the criticism of management at the conference was beside the mark and showed a sad indifference to the principles of scientific administration, the emphasis on the position of the scientific worker in relation to joint advisory committees was indeed timely. More might well have been heard of the importance of this factor of scientific management.

That indeed is the right way, as Sir Robert Watson Watt pointed out recently, for the scientific worker to demonstrate that he belongs to the Third Estat in a true democracy of production. The scientifi method must pervade all stages of production and c use of the product; and the scientific worker mus live with the maker and the user. He can only appl the tradition and skill of his craft, however, in direc co-operation with his fellow-craftsman, and tha influence will only be exercised when he takes hi place as an essential third party, understanding th points of view of both management and labour bu bringing his own independent contribution.

The Conference on the Planning of Science will hav served its purpose if it stimulates scientific workers both junior and senior, to think afresh about thei place in industry and in society, as well as of th functions and scope of science.

MODERN ADVANCES IN TECHNOLOGY

Modern Engineering

By C. H. S. Tupholme. Pp. xi+201+23 plates. (London: Faber and Faber, Ltd., 1942.) 15*s.* net.

IT is one of the disadvantages of war that scientific and technical people are often dispersed far and wide, are unable to meet each other at scientific meetings, and have not, through the technical censorship, access to the latest information respecting new materials and processes. It frequently happens that individuals are simply not aware of the newest developments in science and technology, and this may have an adverse effect on their own work, or delay its successful prosecution. This enforced isolation is mitigated to a large extent by the present text. The author, within the limits tolerated by security, conducts his reader through many technical developments spread over a wide field. Many of these were introduced before the War, but the exigencies of the latter have forced them beyond the experimental stage, until they can no longer be deemed experimental or even developments, but must be included as regular practice in up-to-date manufacture.

The author commences with mechanical power generation from fuels, and shows that appreciable advances in fuel economy must result in the newer types of forced-circulation boilers, mercury boilers, super-charged Diesels, and multiple-fuel engines. Whereas workshop practice was revolutionized by precision grinding, even greater changes have been brought about by automatic oxygen-cutting of forgings to pattern, flame hardening and softening, surface hardening by depositing hard metals, high-speed steel, diamond and cemented carbide tips for super-speed lathe work, the manufacture of gauges and re-surfacing with hard chromium plating, and general restoration of worn parts. While these techniques have improved the product, and lowered the cost by reduction in time of manufacture, many of them would not have been possible without the testing gauges for measuring surface finishes. The piezo effect has been called in to detect the irregularities of a surface in terms of 10^{-6} inch, while the principle of the optical flat, made of quartz, has been applied to the workbench for testing the flatness of a surface by showing the interference bands. Photographing templates on material to be cut and profile projection are becoming routine practice.

For protecting workers and utilizing certain processes requiring absence of dust and a controlled climate, the principle of air-conditioning has been greatly assisted by new safe refrigerants. Air-conditioning in mines, in railway coaches and motor-cars, both for passengers and produce, is becoming common in many parts of the world. Where carbon dioxide is a production by-product it has become a habit to install plant for making 'dry-ice', for which there seems an insatiable demand in many fields. An important production advance has been made by cooling softened duralumin and so delaying the age-hardening, which sets in after two hours, until the material has been worked.

On the chemical side the various plastic materials offer wide scope for designers, and while we are warned by the plastics industry not to be too optimistic about the wholesale replacement of metal parts by plastics, it is obvious that for economy, lightness and conservation of metallic resources, plastics will play a great part in replacing metal objects, and offer new scope in artistic design. New hyper-pressures of 1,000 atmospheres are already in use for ammonia synthesis. Aluminium and magnesium alloys need scarcely be mentioned, apart from the fact that die-cast parts of light-alloy can be designed to require no machine-finishing. A new development is to clad duralumin with pure aluminium, with marked reduction in corrosion, particularly in the hulls of flying-boats. The chrome-nickel stainless steel has the virtue that it is actually toughened by welding, and does not require subsequent annealing, apart from its remarkable retention of strength, impact and anti-corrosion properties at high temperatures. The admixture of lead to steels has vastly diminished the time and cost of machining mass-produced parts. Welding has gone ahead with carburizing techniques, especially valuable for long pipes, while electric valve control has speeded up and made more uniform electric welding. Electro-magnetic and X-ray detection of flaws in metallic bodies has been increasingly used. The development of bright-annealing of metals in controlled atmospheres, especially conditioned town-gas, has many incidental advantages.

On the fabrication side there is the new technique of forming tubes into any contour of section and the electro-deposition of metal inside intricate moulds, such as can be made of rubber or fusible metal. The electrical instruments for precision control, whether of thickness of a continuous product, for limit-gauges or combustion recording, are endless; fluorescent lamps find applications for sterilizing air in schools and factories, detecting manuscript frauds, and for stage and factory lighting. While infra-red lamps have been used for the local baking of coloured car finishes, whole tunnels have been used for processing the complete motor-car. While the advances in traction, marine engineering, and aeronautics make abundant usage during manufacture of all the preceding processes and materials, the last makes several *ad hoc* applications of science, particularly in de-icing, navigation, and blind-flying and landing.

Because the author is discrete in many of his references and also covers so wide a field, he would often appear scrappy to a particular specialist and perhaps obscure to the inquiring layman. The reviewer would normally direct attention to two important fabrication processes which have been omitted; there are in addition a few misprints. Nevertheless, there is a considerable field of usefulness for this type of book at the present time, and, in this type of survey, the author has discharged his task well with regard to prevailing conditions.

RESEARCHES ON FUNGI

A Revision of Melanconis, Pseudovalsa, Prosthecium and Titania

By Lewis E. Wehmeyer. (University of Michigan Studies, Scientific Series, Vol. 14.) Pp. viii+161+11 plates. (Ann Arbor, Mich.: University of Michigan Press; London: Oxford University Press, 1941.) 14*s.* net.

IN this book Dr. Wehmeyer continues his systematic revision of the stromatic Pyrenomycetes, which commenced with his "The Genus Diaporthe and its Segregates" published in 1933. The species concerned are nearly all found in the bark of broad-leaved trees of the northern hemisphere, and with very few exceptions each is characteristically associated with one genus of host plants.

The perithecia are formed in groups in or below stromata which, unlike those of Diaporthe, are not normally associated with black zones of fungus tissue. The primary characters that have traditionally served for distributing the species into different genera are the colour, the septation and the appendages of the ascospores. Often locules are found within the young stromata, or acervuli on their flanks, and from these are produced conidia of two sorts, the broad so-called alpha- and the narrow beta-conidia. Partly through ignorance of the facts, and partly, despite the facts, out of deference to Saccardo's monumental "Sylloge", the perithecia and the two sorts of conidia of the same species have often enough been studied independently of one another; and so have acquired each their vested interest in the systematist's apprehension, and an independent name in his schizophrenic nomenclature. Thus, for example, the single species *Melanconis thelebola* has been made the type species of the three following genera: *Pseudovalsella* von Höhnel for use when it is found producing its perithecia; *Hendersoniopsis* von Höhnel for use when it is found forming its alpha-conidia, and *Cytosporopsis* von Höhnel for use when it is found forming its beta-conidia.

It is Dr. Wehmeyer's particular mission to join together again what has been so unnaturally put asunder; and this he accomplishes by describing and often figuring each available species in all its known forms. He has included under Melanconis all the relevant species with one-septate ascospores, whether hyaline or dark-coloured, and either with or without appendages; and has grouped them into a number of proposed subgenera. Of these, Eu-melanconsis includes all the species with alpha-conidia one-celled, brown or hyaline, and borne in open acervuli—as, for example, the abundant British *M. stilbosum* on birch. Massariovalsa with similar alpha-conidia which are immersed in locules contains only two species, both of them North American; and Pseudomelanconis contains the species with many septate alpha-conidia of either of the Coryneum (that is, of the dry spored), or of the Steganosporium (that is, of the slimy spored) type. Pseudovalsa is restricted to take three species all with unappendaged several-septate ascospores, and fuscous stromata which bear several-septate alpha-conidia of the Coryneum type on an open hymenium. It includes the abundant British *Pseudovalsa lanciformis* on birch. Prosthecium, as here employed to take seven species, has several-septate appendaged ascospores, and stromata which bear in open or closed locules the several-septate alpha-conidia.

Of the other genera, Titania is known only from the type collection of its type species, *T. vesuvius*; its asci each contain only a single ascospore.

In an appendix, the genus Calospora is revised away on the ground that its first species is a Melanconis; all the species included at various times in the genus have been examined and re-distributed. Thus *Calospora platanoides*, well known in Britain on sycamore, appears earlier in this monograph as *Prosthecium innesii* (Currey) Wehmeyer.

The genera Massaria, Aglaospora, Thyridaria and Pseudotrichia differ from all the foregoing in the presence, between the asci, of numerous filiform persistent paraphyses; the author, however, is not yet satisfied that this character justifies their transfer from the Sphæriaceæ to a separate family, the Pseudosphæriaceæ.

It is a great pleasure to register a further stage of Dr. Wehmeyer's progress through the stromatic Sphæriaceæ. The very difficult group of Didymosporæ are now as good as done; and the Phragmosporæ are more than well begun.

WOUND INFECTIONS

Pathology and Treatment of War Wounds

By Sir Almroth E. Wright. (Researches from the Inoculation Department, St. Mary's Hospital, London, W.2.) Pp. viii+208. (London: William Heinemann (Medical Books), Ltd., 1942.) 21*s*. net.

SIR ALMROTH WRIGHT has collected in this volume the addresses and papers upon wound infection that he published during the War of 1914–18. It is a fitting and salutary memorial of the pioneer work on a subject that was forced into prominence by the unprecedented casualties of that war. It is fitting because we can assess the large proportion of that work which has stood the test of time: and we can admire the brilliance of the experimental and technical devices invented by Sir Almroth and his colleagues, by which they were able to demonstrate the defensive action of leucocytes in open wounds and the connexion between 'corruption' and the loss in the tissue fluid of the power to neutralize the 'tryptic' processes of infection; and by which they defined the conditions in which a merely contaminated wound would flare up into gas gangrene, and measured the efficacy of the available methods of antibacterial treatment. It is salutary for its few examples of how too close an adherence to a technical approach, however fruitful, can be a stumbling block, as in the exploration of acidosis in the wounded subject by titrations in soft glass capillary pipettes.

It is obvious, however, that both the author and his publishers have not chosen a time like this to publish a volume that was only memorial in intention. *Streptococcus pyogenes* and *Staphylococcus aureus* are still bugbears of civil and military wounds, and gas gangrene is still with us. The treatment of infected wounds still presents many unsolved problems, and a great deal that Sir Almroth has taught deserves to be lifted out of the archives and set under the noses of surgeons and pathologists to-day. But as a lesson to a younger generation the collection would have been better for a little editing, if only to remove the occasional repetitions of experiments and text figures; and the force and precision with which the minutiæ of the experiments are displayed sometimes obscure the emphasis of the main argument.

A collection of papers like this needs a summary. Of his views in 1919, the author has presented a masterly exposition in the chapter on the physiology of wounds, which all who are concerned with the treatment of wounds would do well to read. The case for 'physiological' as against 'antiseptic' treatment still stands, but it does not stand quite so firmly. One would have liked an interpretation of these views in the light of our present knowledge, particularly in chemotherapy and antisepsis. Sir Almroth might with some justice reply that our present knowledge is still too chaotic for a synthesis; nevertheless it would have been valuable if he had attempted it.

A. A. MILES.

SENSITOMETRY SINCE HURTER AND DRIFFIELD*

By Dr. S. O. RAWLING

THE best memorial to Hurter and Driffield is the continued application of their teaching by the photographic industry. The basis of photographic sensitometry is a characteristic curve of the material under test, and when we remember that the particular characteristic curve in use to-day is still known as the 'H and D curve', obtained by plotting density against the logarithm of the exposure, we realize the excellence of the work which was done so long ago by those two enthusiastic amateurs. The principle of sensitometry remains what it was when Hurter and Driffield left it. The details have changed; the values of the co-ordinates of the curve have been corrected and brought nearer to standardization; new apparatus has been applied to the work and the results themselves are interpreted in new ways which make it possible to link sensitometry much more closely with practical photography. I propose to sketch in outline some of the ways in which the H and D curve has been pulled into shape in order the better to guide those who use photography and those who must provide the best kind of photographic material for each particular purpose.

It is almost fifty-three years since Hurter and Driffield published what was probably the most important of their papers[1]. This was entitled "Photochemical Investigations and a New Method of Determination of the Sensitiveness of Photographic Plates" (*J. Soc. Chem. Ind.*, May 31, 1890). In this paper they described shortly the "laws of absorption of light by opaque black substances" and defined the meaning which they attached to the terms opacity, transparency and density of a negative. They stated their opinion that "a negative is theoretically perfect when the amount of light transmitted through its various gradations is in inverse ratio to that which the corresponding parts of the original subject sent out". They described a photometer for measuring density and went on to report on the behaviour of photographic plates, using this instrument for measuring the response of the plates to exposure and development. The general shape of characteristic curves was demonstrated, and from this they put forward their doctrine of how to obtain negatives which by their definition should be perfect. Lastly, they described a method of calculating photographic speed values from characteristic curves.

My argument will be found to arrange itself quite naturally about the H and D curve. To begin with the density axis, there came early difficulty. The first note of 'trouble' was sounded in 1891 by Hurter and Driffield themselves in a paper[2] on the "Relation between Negatives and their Positives". Using density values determined on their own photometer, they found that the effects of exposures to light behind the negatives were greater than those calculated directly from the densities as measured. They supposed that this was caused by light reflected from the surface of the printing material, and that part of this light was then reflected back again by the negative on to the printing material. They summarized their observations thus: "The coefficient *a* which converts the density as measured, into the printing density, is, for negatives developed by ferrous oxalate, usually a fraction; for pyro developed negatives it is generally nearly 1, if the negatives be used for contact printing; but when the negative is used for enlarging the factor *a* . . . is always greater than 1, even for negatives developed with ferrous oxalate".

Some values of *a* found for contact printing were 0·8, 0·665, 0·577. The principal cause of the wide disparity between these values of *a* and unity was, however, not 'inter-reflection' of light in the printing process, but the unaccounted loss of light by scatter from the negative in their photometer.

Abney directed their attention to the scattering power of negatives, and tried to show that their photometer might not be giving the true optical density. A lively argument followed, from which Hurter and Driffield emerged at last admitting that "the Captain is not yet satisfied that our photometer gives the true optical density" and adding that "density, however expressed, will need different corrections for different operations". Even in this incident we must admit the prophetic nature of their last remark, which was the expression of a truth not always appreciated at the present time.

Abney was right about the scattering of light. The error caused by inter-reflection was small compared with that caused by scatter. Hurter and Driffield's photometer employed direct beams of light between two lamps and a grease-spot photometer, the negative being inserted in one of the beams. Some of the light transmitted by the negative was scattered out of the direct path and never reached the grease-spot. Thus the instrument recorded density values which were too high.

By integrating the whole of the light transmitted by the negative, density values closely approaching contact printing densities are obtained. In general practice, a sheet of white opal glass in contact with the negative serves very well as an integrator, and most of the densitometers now in use employ this device.

Density measurement has not yet been standardized, though with well-designed contact opal densitometers it is possible to compare results obtained in various laboratories without finding serious discrepancies. The comparison is, of course, limited to contact printing technique, and if negatives are to be used in any other way the original caution of Hurter and Driffield must be taken into account: "density . . . will need different corrections for different operations".

The movement towards standardization of sensitometric technique has been most marked in the establishment of standard light sources for sensitometers. The candle and other flame sources have become obsolete, and in their places are electric lamps run at specified colour temperatures.

The commonly used, substandard, vacuum lamp of the photometry laboratories is capable of working well at a colour temperature of 2,360° on the Kelvin scale of temperature, and it was finally decided that such a lamp should be adopted as part of the standard light source for photography. The choice of 2360° K. appears to have followed from the fact that this was supposed to be the colour temperature of the acetylene flame, which had been used with a correcting filter to imitate sunlight.

The 2360° K. light was, however, not adopted as a complete standard. It was capable of much higher output than the candle and it was relatively richer in blue light, but photographic technicians craved for a more evenly balanced distribution of energy such as occurs in direct sunlight. The improvement demanded was not to be gained without sacrifice. It was necessary to filter out the excess of green and red light. The experience of the standardizing laboratories was used in selecting the suitable filter, and after a considerable amount of argument the choice was made from a large series of filters devised and specified by Davis and Gibson[3], of the American Bureau of Standards. This filter converts light from a colour temperature of 2360° K. to the approximate quality of mean noon sunlight at Washington. Thus we are in possession of the specification of a standard light source which can be realized very easily in the laboratory, which gives a fairly even distribution of energy over most of the visible part of the spectrum, and satisfies those who cry for 'artificial sunlight'. In passing, it may be noted that the extreme variations in the quality of real daylight are probably almost as great as between ordinary electric light and mean noon sunlight. For example, the light from clear blue sky is almost as weak in red as the electric light is weak in blue. Nevertheless, the compromise adopted for laboratory work must be considered as a very reasonable one.

---

* Substance of the Hurter and Driffield Memorial Lecture of the Royal Photographic Society, delivered on November 28. The lecture is being published in full in the *Photographic Journal*.

Recently there has been found a need for light sources of very much higher power. The substandard photometric lamps are vacuum lamps and cannot be run at temperatures much above 2360° K., and their total candle-power is in the neighbourhood of 30. The invention of the gas-filled lamp has provided lamps which can be run for long periods at a temperature of about 2850° K. without much change in output. It is quite common to develop several hundred candle-power in a single small lamp of this kind, and there is available another Davis and Gibson filter which converts 2848° K. (say, 2850° K.) to mean noon sunlight. This filter, since it has not such a wide gap of colour temperature to bridge, has a considerably higher transmission; thus the resulting laboratory sample of mean noon sunlight is of far higher available candle-power than that of the 2360° K. source with its appropriate filter.

The establishment of a standard light source has been one of the most valuable results of all the efforts which have been made towards standardization of sensitometric methods. It is, however, far from being the only factor controlling the abscissæ values of the characteristic curve. Exposure, being a product of time and intensity, introduces the question of which of the factors is to be varied in giving the series of test exposures necessary for determining the characteristic curve of the material under test. Hurter and Driffield, probably for convenience, varied time, keeping intensity constant; we now call this a 'time scale' method. They assumed that the results would have been the same if time had been kept constant and the intensity had been varied. But reciprocal variation of time and intensity does not always produce equivalent photographic results. In pictorial photography the varying tones in a given negative are all produced by exposure for the same time (determined by the shutter) to a series of intensities determined by the brightness of the various parts of the image in the camera. It seems, therefore, that the ideal system would be to use an intensity scale in sensitometry. This, however, is easier said than done. On the other hand, time-scale sensitometers are easy to specify and can be constructed with great precision. They have accordingly found great favour in certain applications; for example, they are admirable in providing a scale of exposures for the test negatives employed for checking the performance of developers and developing machines; they are also excellent for checking the uniformity of production of photographic materials. Their main limitation is that they do not give reliable information about the performance of different materials in the camera. The trend has therefore been, in studying the behaviour of different materials in practice, to use so far as possible intensity-scale sensitometers at times of exposure comparable with those employed in the camera.

There are two main difficulties in devising a sensitometer to work on the intensity scale principle. The first of these is the enormous waste of light in providing a wide scale of intensity. The unmodulated light must be of high power in order that the lowest intensity of the scale shall be adequate. It is not uncommon for the last step of a sample exposed in a sensitometer of this type to receive less than one thousandth part of the light received by the first. The second difficulty is that of providing means for varying the intensity over a sufficient range without introducing some change in the quality of the light. The common way of referring to this is to say that it is difficult to make a *neutral* intensity modulator. The common gelatin wedges devised by Goldberg[4] were made of such materials as India ink mixed with bluish dyes to give a reasonable approximation to visual neutrality. They were, however, more heavily absorbing in the blue, violet and near ultra-violet, and more transparent to red and infra-red, than in other regions of the spectrum, and, when employed without proper consideration for this fact, have led to some very misleading conclusions. Other materials, such as highly dispersed graphite and developed emulsion, have been used for casting wedges, but no very satisfactory material for casting really neutral wedges has yet been made available. Stepped wedges can, however, be made by exposing photographic plates in stepwise manner and then developing them. Such wedges are usually sufficiently neutral for ordinary sensitometry.

We have now come to the interpretation of results of sensitometric measurements. Hurter and Driffield considered the photographic speed of a negative material in terms of the minimum exposure necessary to record the deepest black of a scene on the lower extremity of the straight line region of the characteristic curve. It is true that their graphical method of determining speed necessarily implied the inclusion of a little of the foot of the characteristic curve where the slope is changing and is less than that of the straight line, but with the negative materials which they favoured the amount of the foot so included was small, and we must admit that these negatives conformed very closely to *their definition* of a perfect negative if we ignore, as they did, the distortion of tone produced in the image by scattered light within the lens and camera.

One conclusion which has been drawn from the theory of tone reproduction is that, for true tone reproduction *in the print* made from a negative, the product of the slopes of negative curve and positive curve should be unity. Now in making prints on paper it is, more often than not, desirable to use almost the whole tone range of the paper from nearly clear white to a density approaching the maximum black possible. Thus the whole of the characteristic curve of the paper comes into play, and since this curve really is 'curved' and not a straight line for the whole of its course, a complication of the Hurter and Driffield doctrine results. To obtain a perfect print, the angle of slope of each part of the negative curve must be complementary to that of the corresponding part of the paper curve. The highlights of the scene correspond with the darkest part of the negative and with the lightest parts of the print which are recorded on the least sloping part of the characteristic curve of the paper. The negative record of this part of the scene should therefore be on the most steeply sloping parts of the negative curve. At the other end of the brightness scale of the scene the deepest shadows are recorded near the deepest black of the paper where the slope of the paper curve is greatest. This part of the scene will be recorded at a lower density region of the negative curve, and it follows that the slope of this part ought to be lower than of that part of the curve corresponding with the highlights. Thus the negative should include part of what Hurter and Driffield called the under-exposure region of the curve.

The problem is to decide how much of the lower part of the negative curve should be included. As an experimental argument, let us try whether the question may be answered by selecting as a limit that point on the negative curve where the angle of slope is the exact complement of the slope of the paper curve in the region which is to depict the shadows of the scene. With a very large proportion of present-day printing papers, the region of the characteristic curve used for the greater part of the shadows is that of maximum slope ; and this is generally related, roughly at any rate, directly with the contrast-giving power of the paper. By using the 'hardest' printing paper available, it will be possible to creep down a very long way into the foot of the negative curve and still obtain true tone reproduction in the deep shadow regions of the print. Meanwhile, however, what has happened to the remainder of the tone scale ? The choice of the hardest available printing paper will bring with it the difficulty that the whole tone scale of the paper will be brought into action by a very small density range in the negative, and our print, while recording the deepest shadows with accuracy, may exaggerate the middle tone differences and record all the highlights as blank white paper. Thus the limit of our creep down the negative curve in search of speed must be set not only by the conditions necessary for reproducing shadow detail but also by the total density range of the negative. The latter is the main factor which determines the contrast grade of the paper which must be used in printing, a fact very well understood by Hurter and Driffield themselves. The contrast grade of a printing paper may indeed be fairly accurately expressed in terms of the negative density range which it will accommodate[5].

The slope of the curve of the selected printing paper must therefore depend on the density range of the negative from which the print is to be made. The smaller the density range of the negative, the greater must be the slope of the paper curve and vice versa. Our first attempt at deciding how far we may creep into the 'under-exposure' region of the curve has thus failed, unless we first choose a printing paper of the correct exposure range (correct contrast grade) for the negative concerned.

Photographic 'speed' of a negative material thus appears to depend not only on the power to record shadow detail, but also on the density range produced in the negative by the whole scene, that is to say, upon the contrast of the negative as a whole.

As a rule, the main pictorial interest of a photograph does not lie in the extremes of the tone-range but somewhere near the middle, and we are generally satisfied with a print in which extreme shadows are lacking in a little of their detail. That is to say, instead of insisting on perfect tone reproduction in the shadows, we can there accept some compression of the tone-scale, and the product of the slopes of the negative and positive curves can be less than unity.

We must, however, satisfy the general condition that the density-range of the negative and the contrast grade of the paper must be suited to one another. L. A. Jones has, during the past few years, made a thorough investigation of this problem, and has suggested as a criterion of speed for ordinary pictorial negative materials the exposure corresponding with that point on the characteristic curve where the gradient is 0·3 of the average gradient for a negative recording an image brightness-range of 32.

Jones[6] has tested this criterion by a statistical method. He prepared a number of transparencies of landscapes to serve as laboratory originals for his experiments. His use of one of these transparencies will serve to explain his method. A series of negatives having progressive increase of exposure was made upon each of a number of negative materials. From each negative the best possible print was made, using for each the most suitable available grade of printing paper. Thus for each negative a series of prints was obtained. The quality of these prints varied from quite unacceptable through just acceptable to excellent. Jones employed a group of about two hundred observers to answer the question : which, in the series of prints arranged in order of increasing negative exposure, was the first one which could be called excellent ? The majority vote was taken for each series and so the minimum camera exposure necessary to yield *the first excellent print* was established for each negative material. This was eventually done for more than seventy negative materials and for several scenes, and made it possible to establish the relative working speeds of the materials as judged on pictorial results by the average observer. These results were then used as the established yard stick with which sensitometric determinations of speed could be compared.

The comparison between the statistical practical estimate of speed as determined by the selection of the first excellent print and the speed as measured by the fractional gradient method gave a total spread of 0·17 on the logarithmic scale. That is to say, taking the extremes, two films which are really alike in speed would be judged to have speed values not more erroneous than by a factor of antilog 0·17, that is, 1·5, if their speeds were calculated by the sensitometric method. This criterion is still 'under observation' by various standardizing committees.

I began with some discussion about the influence of scattered light upon the value of density. I end by directing attention to the influence of the camera and its lens in scattering light all over the image formed on the negative material. This light is often much stronger than is commonly supposed. It has the effect of distorting the brightness scale of the image in relation to the brightness scale of the scene. It was ignored by Hurter and Driffield, but has been discussed and investigated by various workers, of whom I should mention Goldberg[4] and more recently Jones[7].

This sketch cannot claim to be a full historical record of the progress of sensitometry since 1890, but I believe that it indicates the principal lines of progress, and provides the necessary starting points from which a student may go on to study in greater detail the science of photographic sensitometry.

OBSERVATIONS ON THE PHYSIOLOGY OF COLOUR VISION

By E. N. WILLMER
Physiological Laboratory, Cambridge

THE recent article by Granit[1] stimulates further thoughts upon the mechanism of colour vision, and his results may perhaps be interpreted in a slightly different manner.

There seems to be little reason to doubt that the appreciation of colour, as distinct from light intensity, must depend upon the presence in the retina of at least two elements of unequal sensitivity to the various wave-lengths of the visible spectrum. Two possibilities are therefore open. The first is that if we assume colour vision to be entirely mediated by cones, and the current views upon the structure and behaviour of the fovea give support to this assumption, we must postulate two or more types of cone or of cone sensitivity and trust that further research may lead to their actual demonstration. As the position stands to-day, apart from the existence of coloured globules in the cones of certain birds and marsupials, and apart from the extraction of a pigment, or pigments, with three distinct absorption bands from the retinæ of certain snakes[2], there is no histological evidence which speaks unequivocally in favour of the presence of different cone types distributed in the retinæ of higher vertebrates or of man in such a way as to be consistent with the facts of colour vision. Theoretical curves, expressing the sensitivity of hypothetical cone types (blue, green and red receptors) to different regions of the spectrum, have been constructed[3], but in order that they should satisfy all the necessary conditions the curves have to be so nearly identical in form and position that it is difficult to believe that any neural mechanism could be so delicately adjusted as to be able to appreciate the subtle differences of cone sensitivity which these curves indicate.

The second possibility is that the elements required for colour vision are those which are known actually to exist in the retina, namely, the rods and the cones. Owing to the peculiar structure of the fovea, which is believed to be rod-free, and to the general, though not universal, absence of Purkinje shift from this area, nearly all theories of colour vision have been based on the first possibility and the alternative hypothesis has received but scant attention. Nevertheless, it has several points in its favour and, since there are certain facts which fit more aptly into such a scheme than into others, it may be well to reconsider the hypothesis.

The functional sensitivity of the rods is indicated by the scotopic ocular visibility curve[4]. Their actual sensitivity has probably been most accurately expressed by the scotopic retinal visibility curve in terms of quanta obtained by Ludvigh[5], which among other things makes allowance for the absorption by the eye media. The maximum sensitivity of the rods lies at about 500 mμ, and the curve shows remarkable resemblance to the absorption spectrum of visual purple. Although the curve is normally obtained under conditions in which large quantities of this substance are present in the rods, there is no reason for believing that the differential sensitivity of the rods to different wave-lengths would change under daylight conditions when most, but probably not all, of the visual purple has been bleached. Indeed, Granit[1] has adduced evidence to show that, at any rate in guinea pigs, the rods do function in daylight and with the same differential sensitivity. Dark adaptation and the power to accumulate large quantities of visual purple in the rods may well be a secondary specialization of a more fundamental rod activity.

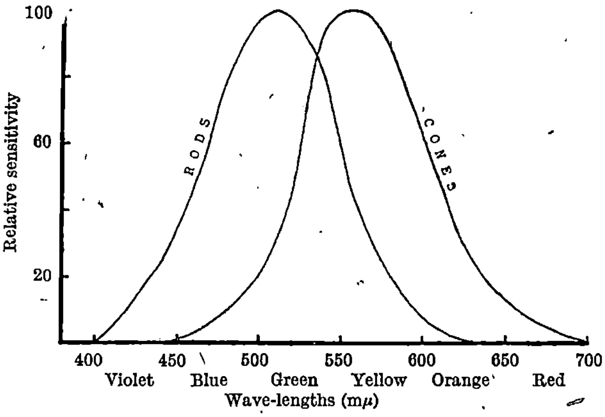

Fig. 1. SCOTOPIC AND PHOTOPIC VISIBILITY CURVES (EQUAL ENERGY SPECTRUM).

The functional sensitivity of the cones is probably closely represented by the photopic ocular visibility curve for the fovea obtained by Sloan[6]. Again, their actual sensitivity is seen in the photopic retinal visibility curve in terms of quanta recently obtained by Ludvigh[7]. The supposition that these curves represent cone activity receives direct support from Granit's observations in which the existence of a dominator is coincident with the presence of cones in the retina, and further support comes from the visibility curves for pure cone retinæ in which the maxima lie in the neighbourhood of 560 mμ. Recent determinations of this curve for the human eye by Ludvigh[7] show it to be remarkably symmetrical, a fact which he considers to favour the view that it represents either the absorption spectrum of a single substance or of a large number. He does not believe it to be consistent with the idea of three or four cone types such as would be required by the Young-Helmholtz theory in its popular form. Fig. 1, in which scotopic and photopic ocular visibility curves are plotted (equal energy spectrum), shows that the human retina in fact contains two elements which are differently sensitive to all regions of the spectrum and, if the rods are capable of functioning in daylight as well as in twilight, as we have seen to be possible, the retina thus contains the minimal necessary apparatus for discriminating between wave-length and intensity.

The visibility curves are essentially sensitivity curves. It is probable, however, that the responses given by the rods and cones are more or less directly related to the sensitivity of these elements and therefore we may properly consider the curves to some extent as response curves and think of the ordinates more in terms of impulse or discharge frequency, probably multiplied by some factor, than in terms of percentage of maximal sensitivity. It is therefore clear that for any wave-length there will be a characteristic ratio of impulses initiated from rods and cones and it will be well to consider the destination of these impulses. Unfortunately the neural connexions of the retina are extremely intricate, but in spite of this a few fairly definite conclusions may be drawn[8]. A great many of the cones, particularly in the regions of greatest colour sensitivity, are separately and individually connected with optic nerve fibres through midget bipolars and midget ganglion cells. It is almost equally certain that a great number of cones project their impulses together with those from more or less adjacent rods on to 'flat bipolar' cells. Thirdly, it is probable, though here we are on less certain ground, that over much of the retina the 'mop bipolar', or 'rod bipolar' of Cajal, conveys impulses arising in rods only. The 'rod bipolar' is absent from the foveal slope and it may be significant that foveal colour vision is weakest for those colours which are seen from Fig. 1 to be purely rod mediated, namely, the violet. Incidentally, it may be pointed out here that in those regions of the spectrum where impulses are propagated from rods or cones alone, that is, at the ends of the spectrum, the eye has no power of discrimination between wave-length and intensity. Returning again to the neural connexions, it is clear that the impulses set up by rods and cones may be transmitted to the brain by at least three routes, each one of which will convey a characteristic frequency of impulses for any given wave-length. If the intensity of the light be varied, the frequency along each route will vary coincidently so that the rod-cone response ratio for any wave-length will remain more or less the same. Much of the detailed analysis of the mechanism must depend upon the nature of this relationship between intensity and frequency of response. Owing to the present lack of direct information on this point the subject must remain one for conjecture and further experimentation. It may, however, be stated that the subjective changes in hue towards blue and orange seen upon increasing the intensity of violet and red light respectively are changes in the direction expected upon the hypothesis under discussion.

Much, of course, will also depend upon the nature of the interaction of the rods and cones when they are both projecting on to the same flat bipolar cell. Presumably there must be some form of summation or of inhibition. There is no direct evidence for either, and there is something to be said in favour of each. Antagonism or inhibition is suggested on grounds of comparative anatomy and physiology. For example, in those animals which have contractile bases (myoids) to both rods and cones, it has been observed that when the rod myoid contracts the cone myoid extends, and vice versa[9]. Inhibition also suggests itself as an explanation of the 'off effect' in electroretinograms. For example, when white light is acting on the retina the rods and cones may completely antagonize each other in their effects upon the flat bipolar cells except perhaps at the beginning ('on effect') and end ('off effect'), when their activities may not be completely synchronous owing to differences in reaction time. Moreover, there is the very interesting observation of Kravkov[10] that the sensitivity to certain colours may be changed, after some thirty minutes, by the application of a few drops of 1 per cent pilocarpine or of 1 : 1,000 adrenalin to the eye via the conjunctival sac. Adrenalin was found to increase the sensitivity to blue-green and reduce it to orange. It was found to have no effect on the colours at the ends of the spectrum, where rods and cones act independently, and there was a neutral or stable point in the yellow-green, strongly suggestive of the point of intersection of the rod and cone curves of Fig. 1. Precisely the reverse effects were obtained with pilocarpine. If this phenomenon be definitely shown to be retinal in origin, it would be explicable in terms of the balance of response set up by rods and cones, but it is difficult to incorporate into current theories.

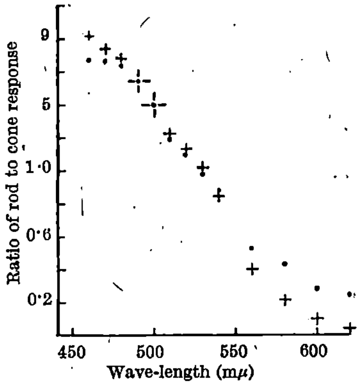

Fig. 2. Rod to cone response ratio observed (crosses) and calculated from colour equation (dots). Wave-lengths of primaries 619, 540 and 466 $m\mu$.

The analyses of retinal activity recorded by Granit[1] are all based upon impulses picked up from optic nerve fibres and therefore are not necessarily recordings from the sensitive elements themselves but from retinal units. For example, it would be possible to interpret his dominator as the response of the cone unit and his modulators as the rod-cone units or rod units.

Any theory of colour vision must satisfactorily explain such things as saturation, hue discrimination, colour contrast, colour fields, colour mixture and complementary colours, colour blindness and so on. It is impossible within the limits of this article to show how each of these can be interpreted on the basis of rod and cone activity, but two or three particular points may briefly be discussed.

The equation $Q = aR + bG + cB$, expressing the relationship between the intensities (a, b and c) of the three primary colours (R, G and B) required to match any given colour (Q), can be modified by substitution for R, G and B the ratio of rod response to cone response, that is, R_1/C_1 for the red primary, R_2/C_2 for the green and R_3/C_3 for the blue. The three primaries are chosen so that $R_1+R_2+R_3=C_1+C_2+C_3$; that is, so that the total rod response is equal to the total cone response, which is the condition for the perception of white light so long as the total intensity is great enough. If this modification be carried out and the values of a, b and c for any given colour be read from the C.I.E. colour chart, the value of Q turns out to be the rod to cone ratio for the colour match. The extent of this agreement is indicated in Fig. 2, where the observed and calculated values for spectral colour matches are plotted together.

Consideration of Fig. 1 might suggest that any combination of rod and cone responses, and therefore any colour sensation, should be obtainable by suitably mixing an extreme violet, stimulating rods only, with an extreme red, stimulating cones only. The effects of raising the light intensities at these wave-lengths sufficiently to produce the necessary rod and cone responses have, however, to be considered. It is significant that the purples obtained by mixtures of red and violet can be converted into white by the addition of a suitable green.

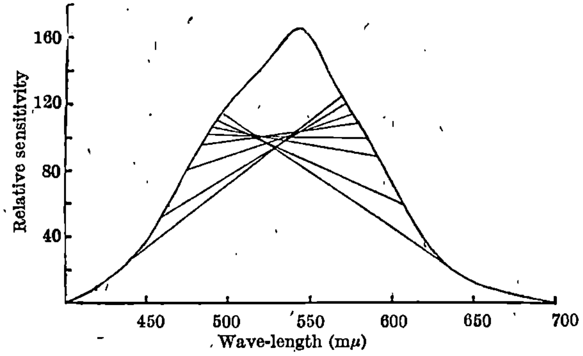

Fig. 3. SUMMATION OF SCOTOPIC AND PHOTOPIC CURVES; COMPLEMENTARY WAVE-LENGTHS CONNECTED BY STRAIGHT LINES.

A particularly interesting, though somewhat mysterious, confirmation of the hypothesis is obtained from a consideration of the effects of summating rod response and cone response. Physiologically, such summation might occur on the bipolar cells or on ganglion cells. The exact position of its occurrence is for the present irrelevant. When the scotopic and photopic visibility curves are summated, the curve shown in Fig. 3 is obtained, and it is clear from a study of this figure that such a curve has all the salient characteristics of the previously entirely empirical colour triangle. The lines joining points on the curve corresponding to complementary pairs all pass through nearly the same point; all wave-lengths shorter than 440 mμ or longer than 640 mμ are complementary to 570 and 496 mμ respectively, and greens can only have purples as complementaries. In this diagram the limits of the spectrum turn outwards, whereas in the colour triangle they are generally represented as turning inwards. The interpretation of this whole phenomenon is obscure, but its significance as a confirmation of the essential part played in colour vision by the facts described by the rod and cone sensitivity curves is manifest.

So far it has been tacitly assumed that, owing to the adaptation powers of the retina, rod and cone responses can be represented on the same scale, that is to say, the visibility curves can be directly compared in order to estimate the frequency of impulses travelling up the separate rod and cone fibres. This is the simplest assumption and may be used as a working hypothesis. It means that should, for any reason, the sensitivity of the rods with respect to the cones be increased or decreased, then some form of colour blindness would result. For example, many of the properties of the deuteranope would receive an explanation if his rods were relatively less sensitive than his cones. Similarly, the protanope would possess rods which were more sensitive than normal relative to the cones. Such quantitative variations in sensitivity of existing units would seem to be a more probable explanation of at least certain types of abnormalities of colour perception than the presence or absence of whole systems of hypothetical sensory units.

These selected points may be sufficient to indicate at least the possibility of interpreting colour phenomena in terms of the known activity of rods and cones. Naturally, there are difficulties, not the least of which is the structure and behaviour of the fovea, but these may perhaps yield to further investigation, and the hypothesis has the merits of not multiplying the sensory elements and of not invoking any structures which are not demonstrable.

SCIENTIFIC DISCOVERIES BY ACCIDENT

By T. LL. HUMBERSTONE

FORTUNA favet fatuis is a familiar Latin tag. Mad or sane, the man of science must thank fortune or accident for useful discoveries in medicine, physics and chemistry. Pasteur said that chance favours those who are prepared. Accidental discoveries may have been forfeited owing to complete concentration on the primary object of the research. But those recorded are numerous. A few examples will demonstrate their value and variety.

Minkowski and von Mehring investigated the pancreas in relation to digestion. A laboratory attendant noticed that the urine of a dog deprived of its pancreas attracted swarms of flies. This was due to increased sugar content. The link between diabetes and the pancreas was established; the disease had been artificially induced and the way was open to Banting and Best for the discovery of insulin. Sir Lauder Brunton declared that his discovery of the effect of nitrites in dilating the arteries was accidental. For sufferers from that cruel disease *angina pectoris*, the drug acts like a charm. Diathermy and the induction of artificial fevers, new and important methods of treatment, were due to a feeling of discomfort noticed by one of Willis R. Whitney's assistants in attending to a high-frequency transmitter. Koch discovered how to separate microbes in a mixed culture through a half-potato left on his laboratory bench. By chance, two medical men discovered that mumps may cure whooping cough. Prof. Archibald Fleming's recent discovery of the bacillus-devouring power of *Penicillium notatum* was due to a chance observation.

In physics, chance discoveries have added to the wealth and happiness of mankind. A spectacle-maker of Middleburg who looked at a weathercock through two lenses was surprised to see an enlarged and inverted weathercock. The discovery was of value for war purposes. Galileo used the telescope to reveal the wonders of the heavens. He died in 1642, the year of the birth of Newton, exemplar of another method of scientific discovery, "travelling through strange seas of Thought, alone". Newton invented the reflecting telescope, the prototype of which is still in the proud possession of the Royal Society. The last—under construction in California—will in due course reveal new heavenly wonders. With apologies to Aristophanes, we may suggest that the frogs of Galvani are the most famous in the world. They hanged by a copper hook from an iron balcony. Galvani noticed that the dead frogs twitched when the wind brought their bodies into contact with the balcony. Thus the galvanic current was discovered, followed by the Voltaic pile, forerunner of the storage battery. Sir Richard Gregory in his book "Discovery" recalls that the Danish professor, Oersted, discovered induced currents by chance during a lecture experiment in 1819. Ampère, the French physicist, suggested that induced currents could be used for signalling at a distance, and two German men of science, Gauss and Weber, invented the first magneto-electric telegraph in 1833, a happy example of international co-operation in science. During Morse's experiments on telegraphy, a mile length of wire alongside a canal broke accidentally. Why not use the water of the canal ? Röntgen and Becquerel were favoured by chance in their important researches.

Iodine was accidentally discovered in 1811 by Courtois in the mother liquor of kelp. In those pre-Mendeléeff days, no chemist would deliberately set about its discovery. Colonel Silver records that ebonite was discovered by the accidental over-vulcanization of a rubber ball. The hypnotic property of sulphonal was discovered by chance. Antipyrine, an invaluable drug, was in a sense a chance discovery. The cyanide industry, of great value to Germany, resulted from the accidental discovery of Prussian blue by Diesbach early in the eighteenth century. That most useful gas, acetylene, was discovered by accident. The American, Willson, and the Frenchman, Moissan, re-discovered calcium carbide in 1892, working independently. Willson heated a mixture of coke and lime in an electric furnace in the hope of obtaining calcium. The resulting grey fusible mass was allowed to fall into a bucket of water and a copious supply of acetylene was produced. Chemists know of the result of a broken thermometer in relation to the oxidation of naphthalene and the synthetic indigo industry. Electro-plating benefited through a workman throwing his comrade's lump of cheese into a vat !

"Webster" defines chance as a supposed material or psychical agent or mode of activity other than force, law, or purpose. Force is as mysterious as space or time ; law in its scientific sense a somewhat fly-blown idol ; purpose in its teleological sense a vague aspiration. Chance relates to statistics, that queen of sciences, sadly contemned during the present War. We daily see provision made at great expense for war contingencies without regard to the principles of statistics and insurance. Nevertheless, physical science teaches that the most improbable events may happen. Stunned and stupefied by the wonders of modern science, the humble disciple is almost forced to the apostasy—*Credo quia impossibile est*. Was Newton a freak of Nature, due to some capricious combination of genes ? Will the world be reduced to chaos by fortuitous collisions of electrons thrown out of their orbits ?

Let us light a candle to the goddess of chance for boons received, for perils avoided !

Chance of chances, all is chance, says the Preacher. In a milligram of radium, about 500 million atoms disintegrate every second, each giving its characteristic radiation. How are these selected for destruction ? Not by seniority nor by lot like shipwrecked mariners on a raft, says Sir James Jeans in his new book, "Physics and Philosophy". Are we offered an escape from determinism, from "the forbidding materialism of the Victorian scientist" ? In the substratum below space and time, Jeans suggests, there may be springs of events including our own mental activities. The world made safe by democracy ! Chance may be "the unsearchable dispose of highest wisdom". *Quien sabe ?*

OBITUARIES

Dr. F. S. Sinnatt, C.B., M.B.E., F.R.S.

The death of Dr. Frank Sturdy Sinnatt on January 27 at the comparatively early age of sixty-two has removed from the ranks of technical science one of its important figures. He was director of fuel research to the Department of Scientific and Industrial Research, succeeding Prof. C. H. Lander in 1931.

Born in Jersey in 1880, Sinnatt was educated in Manchester, graduating M.Sc.(Tech.) in chemistry from the College of Technology in 1901. He obtained his D.Sc. at Manchester in 1930 and was elected a fellow of the Royal Society in 1935.

Originally a lecturer in organic chemistry under Sir William Pope, Sinnatt became interested in coal at an early stage in his career, and from personal research extended his work on the subject by organizing lectures in fuel technology and interesting university students in this relatively new branch of science. Coal technology fascinated him and soon absorbed his entire scientific interest. His researches and lectures attracted the attention of the local coal owners, and in 1918 he organized with them the Lancashire and Cheshire Coal Research Association and eventually became its first director. In 1924 he was appointed by the Department of Scientific and Industrial Research as assistant director of fuel research and as superintendent of the Fuel Research Coal Survey. In 1931 he succeeded Lander as director.

Sinnatt's published papers go back so far as 1906. Two early researches (1923), which are still of academic and technical interest, are the carbonization of coal in the form of fine particles for the production of cenospheres, and the mechanism of the combustion of coal in the form of fine powder. In addition, his method for representing the structure of coal in coal seams is still in use. His papers on the examination of coal in the ground represent the first organized series to appear in Great Britain. His later publications are based mainly upon the work of the Fuel Research Station and the Fuel Research Coal Survey.

Sinnatt was thus not only one of the pioneers of survey work in coalfields, but also it is mainly due to his efforts that the National Survey of Coal Resources in Great Britain is so far in advance of coal surveys started in other countries. The records of the Survey have proved invaluable in war-time in defining the properties of industrial coals and in serving as a basis for allocating these coals to their most appropriate industrial purposes. In general research work also Sinnatt's fertile imagination and infectious enthusiasms were an inspiration and example to his staff.

Sinnatt's interests, however, were not limited to his own organization, since he played an active part in the work of other scientific bodies. He served on the councils of the Institution of Mining Engineers, the Institute of Fuel, the British Colliery Owners' Research Association and the British Coal Utilisation Research Association, and he was a member of the British National Committee and Executive Committee of the World Power Conference. In addition, he was a member of the Iron and Steel Industrial Research Council and chairman of the Blast Furnace Scientific Panel. He was also an original member of the Coal Research Club, an informal group of coal technologists formed just after the War of 1914–18 to further coal research and with the special object of prediscussion of papers intended for publication. In forming this Club he was associated with other personalities well known in fuel technology such as Lessing, Stopes, Wheeler and Seyler. In all these wide activities Sinnatt's opinions and views were greatly appreciated.

Although in later years Sinnatt used up all his energies in the pursuit of science, he had had diverse interests in early life, of which the most important was military training. He joined the Territorial Army in 1908, went to France as a member of the Special Brigade, R.E., in 1915, and later, when forced on medical grounds to return to Great Britain, he assumed command of the University of Manchester O.T.C.

His enthusiasm and kindly personality will be sadly missed by the many people with whom he came into contact, and particularly by the staff of the Fuel Research Organization. J. G. King.

Prof. Rudolph Abel

News has reached Great Britain of the death on his seventy-fourth birthday of Rudolph Abel, professor of hygiene at the University of Jena. Born on December 21, 1868, in Frankfort-on-Oder, Rudolph Abel worked as assistant in Loeffler's laboratory at Greifswald, becoming *Privat-Dozent* in 1893, and afterwards in 1896 assistant at the Institute of Hygiene in Hamburg.

Abel devoted himself particularly to problems more directly concerned with hygiene, publishing many papers dealing with public health and the measures to be taken in combating such diseases as diphtheria and smallpox. He was drawn into the discussion that took place after the War of 1914–18 upon the effect which mass anti-typhoid inoculation of the male population had upon the relative incidence and mortality of typhoid in males and females in subsequent years. The rates for males were found to be very definitely lowered in comparison with those for females, and in this way a reliable indication of the lasting prophylactic effect of the war-time inoculation was obtained. He was consulted as an authority in the judicial trial which followed upon the tragic infections that occurred in Lübeck after the use of Calmette's B.C.G. vaccine.

As a *Privat-Dozent* at Greifswald under Loeffler, a chief whose name, with that of Klebs, will always be associated with the discovery of the diphtheria bacillus, Abel very naturally took a prominent part in the investigations of a number of problems concerned with the natural history and epidemiology of this important organism. The ground for further progress had been recently greatly cleared by Behring's discovery in 1890 of diphtheria antitoxin. Perhaps the most important discovery by Abel in this field was the demonstration in 1894 of the presence of diphtheria antitoxin in the blood of normal persons. This observation underlies much of the present-day practice of immunization against diphtheria. In the blood of diphtheria convalescents Abel found no antitoxin at the time of disappearance of the membrane, but some ten days later antitoxin appeared, only to vanish in the course of succeeding months. He made the suggestion, abundantly verified in recent years, that it is not the mere presence, but rather the amount, of diphtheria antitoxin in the blood that determines immunity.

To the carrier problem in diphtheria Abel made important contributions and also to the importance of fomites as potential sources of infection; in 1893 he had isolated virulent diphtheria bacilli from a box of bricks 6½ months after a child suffering from diphtheria had played with them. Another problem that greatly interested Abel while in his twenties at Greifswald, and to which he devoted a series of bacteriological contributions, was the etiology of certain nasal conditions, in particular ozæna or atrophic rhinitis associated with the presence of organisms of the mucoid-encapsulated group, of which the prototype is Friedländer's bacillus. In his article on these organisms contributed to "Kolle and Wassermann", and to the third edition of this work edited by Kolle, Kraus and Uhlenhuth, he strongly maintained the view that from the very start of the condition of atrophic rhinitis with its accompanying ozæna, an organism found by him and known as the *Bacillus mucosus ozænæ* played a causative part. Writing in 1938, he had to admit that his view of the etiological role of 'Kapselbacillen' in the causation of the ozæna process had not gained the acceptance of rhinologists, and indeed the precise part played by this interesting group of organisms in disease has scarcely yet been adequately elucidated.

To the great compendium of current bacteriological knowledge already alluded to, Abel provided the first chapter, dealing with the historical development of our knowledge of infective immunity throughout the centuries to the time of Pasteur. It is a concise account and should be read in conjunction with the detailed and fully documented study of this theme by Bulloch in his "History of Bacteriology", published in 1938.

After some ten or twelve years of research on pressing bacteriological problems, Abel became more interested in those of general hygiene in its relationship to the State, and he wrote widely on a variety of public health questions. In so doing he departed to some extent from the Koch tradition, which made it almost imperative that holders of chairs of hygiene in German universities should be predominantly exponents and practising professors of bacteriology. For this reason and in view of the fact that his work on bacteriology occupied only his earlier years, Abel's achievements are probably less known to present-day bacteriologists than those of many of his contemporaries who have occupied chairs of hygiene in Germany since the beginning of the present century.

He will, however, be chiefly remembered in Great

Britain as the author of a very popular "Laboratory Handbook of Bacteriology", translated and published in 1907. In Germany, other text-books from the same pen served as practical guides to bacteriology and hygiene and ran into numerous editions.

Abel received the honorary title of *Geheimer Medizinalrat* in 1906 and was appointed to the chair of hygiene at Jena in 1915.

Lord Hirst

Lord Hirst's death on January 23 at the age of seventy-nine has caused poignant regret in many circles, for he was one who touched British social life at many different points. But his outstanding contribution to national life is in the industrial field. That he founded, and built up, the General Electric Company is well known. That he set a new standard in staff relationships in industry, which gave that Company a unique character, is less well known, and is a tribute to the unerring instinct he had for singling out the essentials in all matters which he handled. In this he showed a true scientific spirit by realizing that industry is run by human beings, and broadly its organizations must be made to suit human instincts and aspirations, and not the other way round.

As soon as Lord Hirst felt his Company was large enough to support a big research laboratory, he was able to fulfil a long-standing aspiration and established the Research Laboratories of the General Electric Company at Wembley. His instinct for essentials is again to be noted. His chief objective in founding these laboratories was not the expectation of startling the world with new inventions, welcome as such have been to him when they came. His first object was to provide a scientific general staff for his Company, complete with the facilities which a large laboratory could give them.

The services of this scientific staff were not to be forced on the factory managements. They were to operate at the intermediate levels of the Company, by working on factory problems with the engineering and process staffs in the works. Most of those who are experienced in industry will concur with Lord Hirst in emphasizing this essential place in manufacturing industry, where science should have its beginning and its primary focus.

As soon as it was clear, in 1939, that war was coming, Lord Hirst gave instructions that the research laboratories of his Company, with all their staff and facilities, should be put at the disposal of the Government without regard to commercial considerations. This offer was accepted in the letter and the spirit. The scientific assistance which his laboratories were thus enabled to bring to the war effort was a chief source of satisfaction to Lord Hirst in the closing years of a great life.

C. C. Paterson.

NEWS and VIEWS

The Physical Society : Charles Chree and Duddell Medallists

The Council of the Physical Society has awarded the Charles Chree Medal and Prize for 1943 to Prof. (now Colonel) B. F. J. Schonland and the Duddell Medal for 1942 to Dr. C. R. Burch. Col. Schonland, formerly professor of physics at Cape Town and afterwards director of the Bernard Price Institute of Geophysics at Johannesburg, is now in Great Britain doing scientific work in connexion with the War. Dr. Burch, formerly of the Research Department of the Metropolitan-Vickers Electrical Company, has continued his work in the Physics Laboratories of the Imperial College and the University of Bristol.

Prof. Schonland's work on atmospheric electricity has been primarily concerned with thunderstorm phenomena : first his investigations of the 'polarity' of thunderclouds in South Africa, and his measurement of the discharge from a small tree, which clearly established the importance of point discharges in maintaining the earth's negative charge ; secondly, his systematic long-period observations on the inter-relation of thunderstorms and penetrating radiation in the southern hemisphere ; and thirdly, his use of a rotating-lens camera of the Boys type in a spectacularly successful series of systematic experiments which elucidated the rather complicated succession of discharges forming what is known as a 'stroke' of lightning.

As may be seen in some of the work of the two previous Duddell medallists—Lawrence's cyclotron and Coolidge's multi-sectional high-voltage X-ray tubes—one of the outstanding characteristics of modern physics is the large-scale application of vacuum technique. It is, primarily, in recognition of Dr. Burch's valuable contributions to the advancement of such technique that the present award of the Medal is made. His invention of the oil-diffusion pump, his still for the production of vacuum oils, greases and waxes, and his development of demountable vacuum-tight joints have made possible the attainment of high vacua on an engineering scale and thus greatly increased the range of experimental investigation. It was Burch's work on the production of flat surfaces for vacuum work that aroused his own interest in the grinding of optical surfaces and the possibilities of new developments in optical technique, on which he is now engaged. His remarkable versatility is seen also in his pioneer work in the invention (with Davis) of the induction furnace. In Dr. Burch we see a very rare combination : considerable mathematical ability, exceptional experimental skill, and ability not only to design his instruments but also to construct them in the workshop ; in him Duddell would have recognized a kindred spirit.

The Nuffield Foundation

Lord Nuffield, to whom the world is already indebted for numerous benefactions, large and small, for the benefit of research particularly in social studies, has handed over his holdings in the Nuffield organization to the value of £10,000,000 as a capital fund which will be known as the Nuffield Trust. The fund will be administered by trustees, not exceeding seven in number, and the income will be devoted to (1) medical research and teaching ; (2) organization and development of medical and health services ;

(3) scientific research and teaching in the interests of trade and industry; (4) social studies; (5) care and comfort of aged persons. The normal scope of the Trust's activities will be Great Britain and Northern Ireland. Attention may, however, be given to projects particularly affecting the British Empire, and in regard to items 1 and 3 the provision of scholarships and other assistance for Empire students is included. Lord Nuffield's trusts which are already in being may benefit from the income of the new Trust.

The following have been appointed trustees to manage the new fund thus created: Sir William Goodenough (chairman), who is associated with other Nuffield Trusts; Sir John Stopford (vice-chairman), vice-chancellor and professor of experimental neurology in the University of Manchester; Prof. F. L. Engledow, Drapers' professor of agriculture in the University of Cambridge; the Hon. Geoffrey C. Gibbs; Sir Hector Hetherington, principal and vice-chancellor of the University of Glasgow; Sir Henry Tizard, president of Magdalen College, Oxford, and formerly rector of the Imperial College of Science and Technology; and Miss Janet Vaughan, who is a fellow of the Royal College of Physicians.

Science and Government

THE second annual luncheon of the Parliamentary and Scientific Committee, held on February 11, was attended by several members of both Houses of Parliament, including three Cabinet ministers, and by representatives of the associated scientific bodies. In an address on the organization of scientific effort in Great Britain, Sir John Anderson, Lord President of the Council, who has now become responsible for the Government's scientific services, recalled that Sir Stafford Cripps had already outlined the existing arrangements for scientific research and development in his address on January 30 before the conference on "Planning of Science: in War and in Peace" (see NATURE, February 6, p. 152). Sir John devoted himself therefore to the general principles which he believes should govern such arrangements. He believes that four main conditions must be satisfied: the organization must be an integral part of the Government machine; it should maintain contact with outside scientific bodies; it must not cut across normal ministerial responsibilities; and it must be linked up with a minister who is in a position to see that extra-departmental considerations are not neglected. The present organization of scientific effort, with the scientific advisers to the Ministry of Supply, the Scientific and Engineering Advisory Committees and so on, is, in Sir John Anderson's opinion, meeting these requirements tolerably well, and will provide a good basis on which to build up the type of organization required for the post-war world. Sir Robert Robinson spoke on the importance of the international control of explosives. As all the explosives in use by armed forces depend on the supply of nitrates, he urged the control of synthetic nitrate and similar plants as a measure for ensuring that aggressor nations shall not resort to war.

Parliamentary and Scientific Committee

ACCORDING to the annual report for 1942 of the Parliamentary and Scientific Committee, the membership now includes thirty-three organizations associated with scientific work and seventy-four members of the Houses of Parliament. During the past year, the main work of the Committee has been connected with the better utilization of scientific men in the war effort. A memorandum on the subject was prepared and a strong deputation saw Mr. R. A. Butler, then chairman of the Scientific Advisory Committee. Later, a motion urging the establishment of a Central Scientific and Technical Board was tabled in the House of Commons. This motion was allowed to lapse, after several questions designed to elucidate the position had been asked in the House, on the understanding that the functions of the scientific advisers to the Ministry of Supply would be widened as they became established. The Committee is watching the position. Discussions arranged during the year dealt with the dissemination of scientific knowledge among farmers (see NATURE, June 27, p. 722), the Industrial Health Research Board, the use of geology in war-time, pasteurization of milk and visual efficiency in factories. The secretaries of the Committee have continued to issue *Science in Parliament*, which summarizes important Parliamentary proceedings relating to science and technology. The following officers have been appointed for 1943: *President:* Lord Samuel; *New Vice-Presidents:* Captain L. F. Plugge, M.P., Prof. B. W. Holman, Mr. R. B. Pilcher (Institute of Chemistry); *Chairman:* Mr. E. W. Salt, M.P.; *Vice-Chairman:* Prof. J. A. Crowther (Institute of Physics); *Deputy Chairman:* Mr. M. P. Price, M.P.; *Hon. Treasurer:* Mr. C. S. Garland (Institution of Chemical Engineers); *Hon. Secretary:* Dr. W. R. Wooldridge (National Veterinary Medical Association).

Colonial Policy

A SOMEWHAT inconclusive debate on Colonial affairs took place in the House of Lords on February 9. The matter was raised by Lord Trenchard, who asked whether the Government could make any statement on methods of staffing and administering the Colonial Empire. Lord Trenchard referred to his previous inquiry on the subject last May, when he brought forward five matters for discussion: recruitment of the Colonial Civil Service, organization of a single interchangeable and independent Service, a Colonial Staff College, creation of a Colonial Advisory Board, and the possibility of grouping the Colonies into larger units. In the interval, other debates on the general subject have taken place, and in one of them Lord Listowel remarked that we now have an opportunity for atoning for past neglect of the Colonies. Lord Trenchard emphatically repudiated the suggestion that there has been neglect, showing that the British Colonial administration has brought peace and prosperity in its train; and he denied the suggestion that Great Britain has enriched herself at the expense of the Colonies. This point, it may be noted, was also made by Mr. R. G. Casey, now Minister of State in the Middle East, and a former member of the Australian Government, in a broadcast address delivered on February 14. Lord Listowel followed Lord Trenchard and discussed particularly the staffing and recruitment of the administrative services. He pointed out that high academic achievement is insufficient, and should be supplemented by special courses taken after having practical experience in the Colonies. Lord Elibank referred particularly to the difficulty of grouping Colonies. The importance of introducing local inhabitants into the administrative system was widely emphasized.

The Duke of Devonshire, Parliamentary Under-Secretary of State for the Colonies, replied to the debate. He said that the Colonial Office is not so academic as is often assumed; adding that he generally finds someone with first-hand and recent knowledge of any particular Colony at his immediate disposal. As regards suggestions for improvements in recruitment, they would be borne in mind; he pleaded that difficulty of war-time communication has made consultation slow and laborious. The Colonial Service consists of individuals employed under a variety of geographical conditions by a variety of Colonial Governments; European officers form only a small fraction of the whole. Hence re-organization of the Service is a matter, not for the Colonial Office alone, but for legislative bodies all over the world. Two main principles of development must be recognized; there must be partnership of the Colonial peoples in administration, but a substantial body of officers of European stock is still necessary to supplement local man-power. The formation some thirteen years ago of a series of unified professional services has provided a pool of highly qualified men who can be posted to any Colony and moved from one to another. Nevertheless he agreed that there should be nothing static in Colonial administration, and the whole position as regards this and other points raised is being examined in association with the Colonial Governments.

Packaging Research Committee

The Printing and Allied Trades Research Association has set up a Packaging Research Committee to carry out investigations concerned with packages of which paper, board, film or foil form the main part. The research work will be carried out by the Association, which will set up a new department for the purpose, using its own laboratories or other research organizations as may be most appropriate. Preliminary consideration will be given to the systematic investigation of the elementary principles of the relation between the make-up of packages and their performance in use. The Association will also collect empirical data from individual firms in Great Britain and abroad with the view of obtaining a basis for long-range research. The outline programme already drawn up includes investigations on the penetration of various packaging materials by vapours, liquids, gases, heat and light, the effect of impregnation with various materials, damage by pests, design of packages, methods of sealing, and optimum use of automatic packaging machinery. Some ninety members of the industry have already applied for membership under the scheme. Communications should be addressed to the Director of Research, Printing and Allied Trades Research Association, 101 Princes Gardens, Acton, London, W.3.

Race Theories

On February 8 a well-attended meeting of the Manchester University Branch of the Association of Scientific Workers heard a lecture on "Race Theories" by Prof. F. Wood Jones. The differences between various types of men are sufficient for them to be classified in three distinct species, the leiotrichi or mongol, the ulotrichi or negro, and the cymotrichi. The last-named species, to which we belong, is rather less easy to define. Since interbreeding between the species readily occurs, the view that there is only one species, *Homo sapiens*, has been widely held. Numerous zoological and botanical examples of the interbreeding of species with the production of fertile offspring are now known, and it is therefore again justifiable to speak of three distinct species, particularly as they can be distinguished in embryo less than three months old, as well as in fossil remains of the pleistocene period. Within these species are numerous sub-species or races, each with distinct characteristics. Segregation whether geographical, or religious and political as in the case of the Jews in Europe, tends to produce such races. Nevertheless in Europe at the present time there is no nation in which more than 10 per cent of the population belongs to a pure race. The belief that half-breeds of certain races inherit the worst qualities of both races is quite unfounded. The belief probably arose because in certain cases only the least desirable elements in both races produced such half-breeds. Professor Wood Jones strongly advocated intermarriage between all races.

Multi-part Domestic Electrical Tariffs

A paper under the title "Towards the 'Correct' Domestic Multi-Part Tariff" was read by P. Schiller before the Institution of Electrical Engineers in London on February 4. The author pointed out that the principle of multi-part costing and charging is again attaining particular importance in the intensive development of the domestic thermal load, which requires the unit charge component of multi-part tariffs to be reduced to the bare minimum. The necessary corollary of allocating to the standing-charge component the bulk of the actual standing costs involved in giving supply is impracticable with conventional two-part tariffs. At present the standing charge covers little more than the standing costs due to the demand for lighting and small domestic appliances, which is but a small fraction of the total demand of modern domestic installations. Hence the bulk of the standing costs due to the domestic thermal load must be averaged out on the unit-charge component.

A 'correct' domestic multi-part tariff must take account of the individual consumer's demand, and this becomes more and more justifiable as inter-consumer diversity grows poorer in consequence of the predominance of the space-heating load. Owing to the rigid character of lighting and cooking demands, it appears to be sufficient to consider the individual consumer's demand only in connexion with the elastic requirements of water-heating and space-heating. Tariff charges based on actual demand can be put into effect by either recording or limiting consumers' maximum demands during periods of heavy load on the general supply system. As to the second alternative, the 'contract-demand' method can be developed to such an extent as to be capable of everything the maximum demand indicator method achieves, while obviating the drawbacks of the latter. Thus a 'correct' domestic multi-part tariff may be found in a revival and modernization of the contract-demand method. Whether such a tariff is also an ideal one is open to discussion. But the principle of charging domestic supplies on the basis of both consumption and demand is worth reconsidering at all events.

Boiler-House Measurements and Control

A paper by G. H. Barker and A. L. Hancock, read before the Institution of Electrical Engineers in London recently, on boiler-house measurements with special reference to the efficient utilization of fuel, reviews the development of boiler-plant instrumentation from the early use of measuring instruments as mere safety devices to the modern employment of remote centralized control, based upon the comprehensive measurement of the operating conditions. As improvements in plant design and operating efficiency are governed by the degree to which their dependent factors are known and understood, exploratory measurement must embrace all the measurable quantities, while the operating measurements must include those of all the variables which are susceptible to regulation. A table of essential measuring instruments for shell-type and water-tube type boilers is included in the paper. Remote manual control is compared with automatic control in order to show that, as measurement is now the acknowledged basis for control, it follows that the measuring instruments which detect and report the adverse tendencies should be used to institute the corrections needed to arrest them, wherever this is practicable.

Standards of Electrical Measurement

Dr. L. Hartshorn has written an interesting progress review on this subject (*J. Inst. Elect. Eng.*, 89, Pt. 1, No. 24; Dec. 1942). Following introductory paragraphs dealing with the general character of measurement, an account is given of the more recent experimental researches of the standardizing laboratories, and of the present legal and international position of the various electrical units. The review is presented under the headings of units and standards, fundamental and derived measurements, the absolute system and the international position. The section on the absolute system deals with the measurement of inductance, current, resistance and voltage, capacitance and quantity of electricity, power and energy, practical standards, and frequency. The remarks relating to the international position give prominence to the M.K.S. system.

Maternal and Child Welfare in Venezuela

Discussing maternal and child welfare in Venezuela (*Bol. Of. San. Panamericana*, November 1942) Dr. Pastor Oropeza refers to the creation in 1936 of the Ministry of Public Health and Social Welfare as providing a sound foundation. At the present time, these services are under the direction of the Division of Maternal and Child Hygiene. The Ministry operates through health units and health centres, and offices in places where centralized local public health services have not been organized. In 1942 there were 37 fully qualified health units, 4 health offices and 61 rural medical officers. Regulations have been issued for the supervision and education of midwives. In 1936, pregnancy was made the subject of industrial legislation. Obstetrical assistance and post-natal care are given to the wives of insured workers. The official infant death-rate has fallen in Venezuela from 124 per 1,000 live births in 1936 to 121 in 1940, but these figures are probably inaccurate owing to many births not having been registered until baptism, and numerous deaths were probably not reported. Child welfare work includes examinations and immunizations carried out by the various health centres, assisted by public health measures. During 1930–41, 45 stations for distribution of milk to children were organized throughout the country in connexion with health centres. Attention is also given to the care of sick children mainly through the welfare agencies of the States and municipalities. Other developments include the creation of a course in clinical pædiatrics and puericulture, and a new law making these subjects compulsory for medical qualification.

Commemoration of Copernicus in the United States

The Kosciuszko Foundation of New York is making arrangements to celebrate the four hundredth anniversary of the death of Copernicus on May 24. Invitations to take part have been sent to American universities and other institutions by Dr. Henry N. MacCracken, president of Vassar College and also of the Kosciuszko Foundation. With Poland now associated with the United States in the war of survival and several million citizens of Polish extraction living in the United States, it is the desire of the Foundation to make the occasion an outstanding event in the history of science.

Announcements

The Committee of the Athenæum has elected the following under the provisions of Rule II of the club, which empowers the annual election by the committee of a certain number of persons of distinguished eminence in science, literature, or the arts, or for their public services: Sir William Stanier, scientific adviser to the Minister of Production; Sir Thomas Lewis, director of clinical research, University College Hospital; Sir Bernard Pares, lately professor of Russian history, University of London.

The Managers of the Royal Institution have awarded the Actonian Prize of one hundred guineas for the year 1942 to Dr. Alexander W. G. Ewing and Mrs. Ewing for their investigation concerning the detection, measurement and assessment of deafness, their pioneer work upon hearing aids, and the development of their successful technique for education by the 'hearing lip reading' method.

Dr. Robert E. Wilson, president of the Pan American Petroleum and Transport Company, has been awarded the Perkin Medal of the American Section of the Society of Chemical Industry for outstanding work in applied chemistry. His work includes research on such varied subjects as flow of fluids, corrosion, motor fuel volatility and contributions in the use of tetraethyl lead.

The Institute of Industrial Administration is organizing a Conference on Training for Industrial Management, to be held at the Waldorf Hotel, London, during March 5–7. The opening session on March 6, on "Management and Nation", will be addressed by the Archbishop of Canterbury. Other sessions will be devoted to the position of management in industry, external and internal training for industry, and the training required by a director. Particulars can be obtained from the Institute, Artillery House, Artillery Row, London, S.W.1.

The Council of the Harveian Society of London announces that the subject of the Buckston Browne prize essay for 1943–44 will be the use and abuse of sulphonamides. The essay must be sent to the Treasurer of the Society, 14, Devonshire Street, W.1, by October 1, 1944.

The German Academy of Natural Science at Halle proposes to issue an edition of Goethe's scientific works.

Stability of Ascorbic Acid in Metaphosphoric Acid Extracts

It is frequently impossible to perform an analysis of ascorbic acid in foods immediately after sampling. In some cases a delay of as long as 24 hours is unavoidable, and doubts have arisen as to the reliability of the results then obtained. Most analysts now employ metaphosphoric acid or a mixture of metaphosphoric and trichloroacetic acids as the extractant, when determining ascorbic acid by titration against 2,6-dichlorophenolindophenol. We have accordingly investigated the rate of oxidation of ascorbic acid in 5 per cent metaphosphoric acid solution and in a mixture containing 2 per cent metaphosphoric acid and 5 per cent trichloroacetic acids. The solutions were pure ascorbic acid and extracts of cabbage, potato and swede.

Ascorbic acid suffers photochemical decomposition if exposed to light, when present either in pure solutions or in foods such as milk[1,2,3]. Kellie and Zilva[4] found that the destructive influence of light was less at *p*H 3·0 than at alkaline reactions. We have found that even in very acid solutions (5 or even 20 per cent metaphosphoric acid), ascorbic acid is not stable unless the solutions are kept in the dark.

Fig. 1 shows that, in the dark, pure ascorbic acid was stable in 5 per cent metaphosphoric acid solution for at least 2 days at a temperature of 20° C., whereas if kept in daylight 50 per cent of the ascorbic acid was oxidized within 53 hours. When the solution was kept at 0° C., in the dark, there was no deterioration over a period of six days. Irradiation of the solution with ultra-violet light had an even greater destructive effect than daylight.

Ascorbic acid in extracts of various vegetables was less stable, whether in the light or in the dark, than were solutions of the pure acid. Thus ascorbic acid in a cabbage extract in a mixture of 2 per cent metaphosphoric and 5 per cent trichloroacetic acid was stable for two days when kept in the dark at 20° C. (Curve 1, Fig. 2), after which oxidation proceeded at an increasing rate until at the end of ten days 50 per cent of the ascorbic acid had disappeared. In swede extract made with 5 per cent metaphosphoric acid (Curve 2, Fig. 2) the oxidation was a little more rapid, but after twenty-four hours 95 per cent of the ascorbic acid remained in the reduced form. The stability of ascorbic acid in both cabbage and swede extract was increased if the extracts were kept at 0° C. in the dark; 5 per cent metaphosphoric acid extracts of cabbage or swede have both been kept for more than sixty hours without loss.

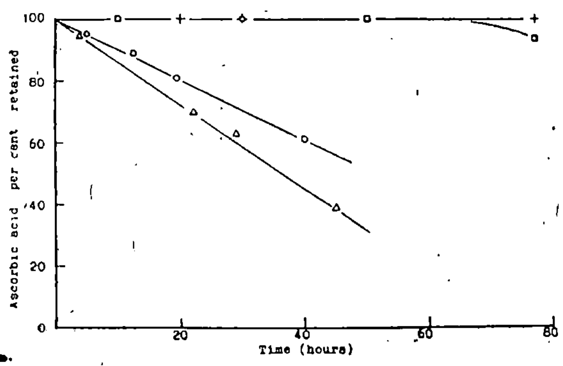

Fig. 1. STABILITY OF SOLUTION OF PURE ASCORBIC ACID IN 5 PER CENT METAPHOSPHORIC ACID.

△——△ Solution irradiated with ultra-violet light at 20° C.; ○——○ Solution kept in daylight at 20° C.; □——□ Solution kept in dark at 20° C.; +——+ Solution kept in dark at 0° C.

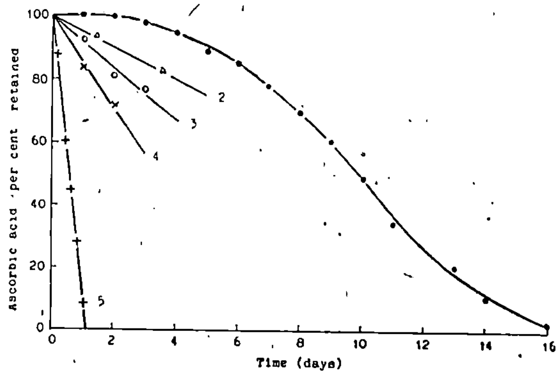

Fig. 2. STABILITY OF ASCORBIC ACID IN METAPHOSPHORIC AND TRICHLOROACETIC ACID EXTRACTS OF CABBAGE, POTATO AND SWEDE.

Solution 1. Cabbage extract: 2 per cent metaphosphoric and 5 per cent trichloroacetic acid. Solution 2. Swede extract: 5 per cent metaphosphoric acid. Solution 3. Cabbage or potato extracts in contact with deposit: 2 per cent metaphosphoric and 5 per cent trichloroacetic acid. Solution 4. Cabbage or potato extracts in contact with deposit: 5 per cent metaphosphoric acid.	Solution kept in the dark at 20°.
Solution 5. Cabbage extract: 2 per cent metaphosphoric and 5 per cent trichloroacetic acid. Swede extract: 5 per cent metaphosphoric acid.	Solution kept in daylight at 20°

When the centrifuged deposit was left in contact with the supernatant acid extract, the ascorbic acid was oxidized somewhat more rapidly. Curves 3 and 4 show the rate of oxidation in the metaphosphoric - trichloroacetic acid mixture, and in 5 per cent metaphosphoric acid respectively at 20° C. Curves 3 and 4 have been constructed from analyses of samples of cabbage or potato which were estimated at once and after one, two and three days, and each point is the mean of the results obtained from a considerable number of samples. After twenty-four hours in the dark at 20° C., 91 per cent of the initial ascorbic acid remained in the metaphosphoric - trichloroacetic acid mixture, while in the 5 per cent metaphosphoric acid mixture the residual ascorbic acid was 85 per cent of the original amount. When kept in daylight, the rate of oxidation in these food extracts was increased to such a degree that 50 per cent of the ascorbic acid was destroyed within twelve hours (Curve 5, Fig. 2).

Comparison of these results with those in Fig. 1 shows that the rate of oxidation of ascorbic acid in metaphosphoric acid extracts of foods in daylight at 20° C. is some two to three times greater than that of the pure substance. This is not surprising in view of the presence in foods of substances such as copper, iron and riboflavin, which catalyse the oxidation of ascorbic acid.

Conclusion. Samples taken for analysis for ascorbic acid in 5 per cent metaphosphoric acid or a mixture of metaphosphoric and trichloroacetic acids should be kept in the dark if any delay between extraction and analysis is likely to occur. If the extracts are kept at 0° C. there should be no loss over a period of two days; if kept at room temperature analysis should be completed within twenty-four hours. Loss is less when the supernatant extract is separated from the precipitate.

Automatic Separation of Wet from Dry Grain for Storage

WHEN wheat is too damp for prolonged storing, which is usually true of the home-grown crop in Great Britain, deterioration, accompanied by heating and development of fungi, is commonly observed to occur first in small patches buried in the bulk. These are the wetter portions of the bulk. If all the grain is very damp, heating may spread from these foci throughout the bulk; but even if this does not happen, development of fungi in such small areas may produce sufficient taint throughout the bulk to make the grain unfit for milling. This experience, common in the storage of English grain, has been confirmed in America by Kelly and others[1] by extended storage tests. Consequently, in so far as it is affected by water-content, the storage life of a bulk of grain depends on the maximum water-content at any point, rather than on the mean water-content of the bulk. Hence, for any mean water-content, the maximum storage life is reached when variations from the mean are reduced to a minimum. Such variations are greatest in grain harvested by combine, often because of irregularities in ripening in the field; but non-uniformity of water-content causes difficulty in storage of grain in Great Britain whatever method of harvesting is used. The variations might be brought to a minimum by thoroughly mixing every load of grain, but this is impossible without large-scale machinery, and even the handling plant of a large modern silo is barely adequate for the purpose. Consequently, it is seldom certain that grain in bulk is of uniform water-content. Nevertheless, mixing and thorough drying of the entire crop are the only methods at present available to ensure that English wheat shall have an adequate storage life. Increasing production is putting an extreme strain on drying facilities; therefore, an alternative to drying the whole crop is desirable.

The development of rapid electrical methods for the determination of water-content of grain has made it possible to design a machine to separate the wetter portions of a grain stream. This process will eliminate wide water-content variations while lowering the mean water-content of the bulk. After this separation the drier fraction (which may be a large proportion of the whole) will have a longer storage life than would be expected of a normal, more heterogeneous, bulk of the same mean water-content. The small wetter fraction may easily be given priority for drying. Because of its high water-content a greater amount of water will be removed by a given quantity of heat, or by a particular size of drier, than if the original bulk had been dried before separation.

The variations in water-content in a single freshly threshed bulk are so wide that a separator which would be capable of reducing this wide range very greatly need not act with great precision. Accordingly a simple physical measurement may be made the basis of operation. In this laboratory a machine has been constructed in which grain passes in a stream of constant thickness between two metal plates acting as a condenser. The current passed to earth by this condenser, when an alternating potential of constant frequency is applied to one plate, controls the separating mechanism. This consists of a hinged metal plate which diverts the stream of grain to either of two chutes according to the current passing through a spring-loaded adjustable relay. It has been found satisfactory to convey the grain stream between the condenser plates on a moving cotton band, but some mechanical disadvantages of this arrangement are overcome if the surface of a revolving cylinder is substituted for a moving band. A machine of this type, large enough to deal with grain in commercial quantities, is now under construction in this laboratory.

The total current passed by a condenser under the conditions described is partly capacitative and partly resistive, the proportions of each varying with the water-content of the grain between the plates. It cannot, therefore, be claimed that the condenser current measures with precision the water-content of the grain stream, but the precision obtainable is adequate for the purpose. If, for other purposes, a separator working at a more precisely defined water-content were required, a circuit of one of the types developed by Dr. Hartshorn, of the National Physical Laboratory, would be very suitable.

'Pasmo' Disease of Flax

DURING the summer of 1942 a culture of a fungus was received from Dr. R. M. Nattrass, of Kenya, who stated that the organism had been isolated from flax plants suspected of being affected with 'Pasmo' disease and that he believed it to be *Sphærella linorum* (Naoum.) Wr., the cause of the disease.

Examination of the fungus showed that its characters were in close agreement with those recorded for *S. linorum*. To investigate its pathogenicity, flax plants which were at the flowering stage were sprayed with a suspension of spores prepared from a single-spore culture. They were then covered with bell jars for four days. Lesions, identical with those described for 'Pasmo' disease, appeared on the plants some fourteen days after inoculation. The organism was re-isolated from pycnidia produced on these lesions and re-inoculated into healthy plants. Positive results were again obtained and the organism again re-isolated. Control plants sprayed with water at the same times remained healthy. Inoculation experiments were made both under glasshouse and open-air conditions and, in each case, infection resulted. Special precautions were taken to isolate the plants used in these trials, and they were destroyed immediately after the work had been concluded.

Lesions were produced on both leaves and stems, mainly on the upper portions of the plants. They were brown in colour and at first small, somewhat elongated, and extended only part of the way round the stem. Later, they increased in size and ultimately encircled the stem; it was common to find diseased and healthy portions of the same stem occurring alternately. As the result of encirclement, the portion of the plant above the lesion was frequently killed and this 'strangling' effect is aptly described by the common name given to the disease. Illustrations of typically infected stems, including an example showing how the top of the plant may be killed, are seen in Fig. 1. Fig. 2 is a photograph of a typical lesion showing the presence of pycnidia. In some cases the stem lesions are not unlike those produced by an attack of browning (*Polyspora Lini* Laff.), but the production of pycnidia in the case of 'Pasmo' attack is a clear and reliable distinguishing characteristic. The minute cream-coloured acervuli produced by *P. Lini* are not commonly found in the field but develop readily on the incubation of infected stems. Fig. 3 shows a typical browning lesion, while Fig. 4 shows such a lesion after incubation when acervuli have been produced in abundance.

'Pasmo' disease was first described by Spegazzini[1] in the Argentine; he named the causal organism *Phlyctœna linicoli*. Garassini[2], also working in the Argentine, renamed it *Septoria linorum*.

The disease is known to occur in the Argentine (Spegazzini[1]); United States of America (Brentzel[3,4]); Canada (Henry[5]); New Zealand (Cunningham[6]); Siberia (Natalyina[7]); Yugoslavia (Rost[8]); Rumania (Rost[9]); Germany (Wollenweber and Krüger[10,11]); Hungary (Kremmer[12]); and Peru (Rome[13]). It has not been recorded for the British Isles.

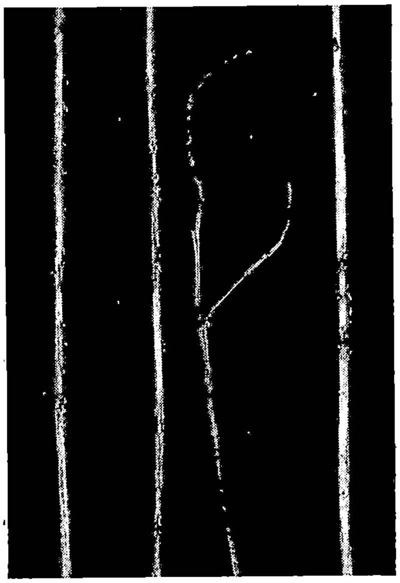

Fig. 1.

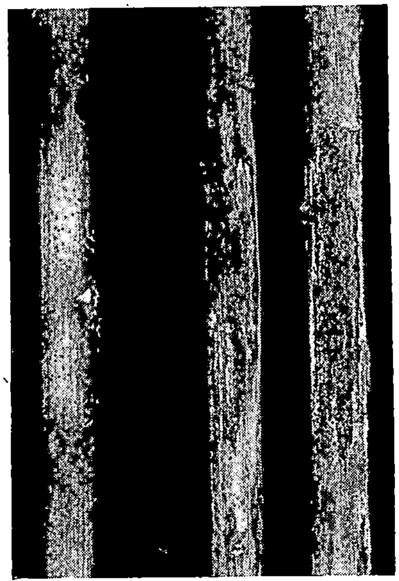

Figs. 2 3 4

Brentzel[14], who has studied the disease in the United States in considerable detail, states that pycnospores may accumulate on diseased stems and stubble, from which infection originates in the following spring. He also states that the disease is transmitted by the seed.

No evidence has yet been produced to show that 'Pasmo' can be successfully controlled by seed disinfection. Various workers have studied the resistance and susceptibility of flax varieties to attack but little information is available regarding the behaviour of those fibre varieties commonly grown in the United Kingdom. As the disease has not yet appeared in the British Isles, every effort should be made to prevent its occurrence, and the greatest care should be taken to ensure that flax seed imported into the United Kingdom is free from contamination with *S. linorum*.

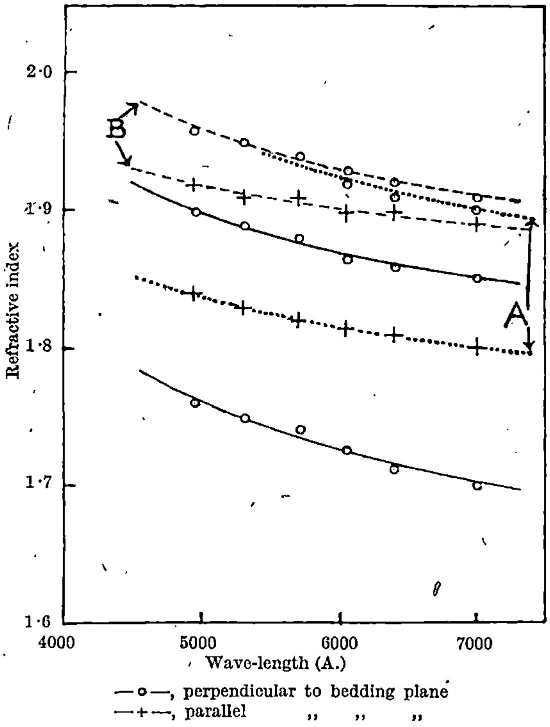
Optical Dispersion for Coals

USING the apparatus previously described[1], together with a set of Wratten Monochromat light filters Nos. 70–75, it has been possible to examine the variations of refractive index over a limited range of wave-lengths in the visible spectrum for several typical coals of varying rank. The Brewster angle was determined with each filter placed in turn before the light source, and the corresponding refractive index calculated. The determining factor limiting the accuracy of the measurements was the stability of the photo-cell amplifier. Under the most unfavourable conditions the limits of accuracy of the determination of refractive index were ±0·01. In general, the accuracy was greater than this.



Typical results are given in the accompanying figure. For two isotropic coals, the lower full-line curve is for a free-burning coal and the upper for a coking coal. For the anisotropic coals measurements were made in directions perpendicular (rings) and parallel (crosses) to the bedding plane. The curves *A* are for a Welsh anthracite and the curves *B* for a Welsh steam coal.

For all the measurements made in a direction perpendicular to the bedding plane the dispersion curves are approximately parallel; the curves for the measurements made parallel to the bedding plane are themselves parallel. But the slopes of the two sets of curves, shown respectively with rings and crosses, are markedly different. From these results it would appear that the refracting material varies but little with the rank of the coal. The difference shown in the two directions would, however, be consistent with a large-scale structure in which anisotropic units occur with preferred orientation. On such a supposition the isotropy of the lower rank coals could be obtained by completely random orientation of the same anisotropic units.

Thanks are due to Mr. J. G. Bennett, director, and Dr. D. H. Bangham, principal scientific officer, of the British Coal Utilization Research Association, for their kindness in providing the specimens.

Nature of Entropy

THE opening paragraph of Mr. Ian Campbell's letter[1] on the nature of entropy reads somewhat strangely to one fresh from the perusal of "Physics and Philosophy" by Sir James Jeans. Campbell argues that "a quantity which fits so completely into the mathematics of the subject must surely have some relation to the physical facts", and suggests that entropy may be regarded as analogous to momentum in mechanics. Jeans asks whether we should adopt mechanical *explanations* of Nature or the mathematical *description* of Nature, and concludes: "whether the ghostly remains of matter should be labelled as matter or as something else is mainly a question of terminology" (p. 216).

From the educational point of view, however, it is in my opinion necessary that the beginner in a scientific subject should be given at the outset some familiar mental picture. Some physical analogies of the "ghostly" quantity entropy have been described in a recent text-book[2], and it may be pointed out that before the end of last century it was customary in the Royal Naval Engineering College, Devonport, to regard entropy as 'thermal inertia', and to use rotational motion especially to illustrate thermodynamic principles, treating entropy as 'rotational inertia' (moment of inertia)[3]. In his presidential address to the Physical Society in 1911, Prof. H. L. Callendar stressed the correspondence between entropy and 'caloric'. On this view, we may regard Joseph Black's 'matter of heat' as equivalent to a mathematical function, or alternatively we are in some measure entitled to regard entropy as the modern expression for caloric.

In order to support his view as to the nature of entropy, Campbell proposes the adoption of a new scale of temperature so that "temperature may become proportional to the square root of heat energy and, in the kinetic theory, to the mean molecular velocity". I am not at all clear as to his attitude to Lord Kelvin's absolute scale of temperature—one sentence in his letter asserts, or at least suggests, that temperature "cannot be measured absolutely". On this subject there is a recent article[4] on a dynamical treatment of the elements of heat by Dr. G. Burniston Brown, in which an elementary and more directly empirical discussion is given in a form suitable for beginners. In this connexion it is worth while directing attention to the fact that momentum, depending on the first power of the velocity, is a vector quantity, having direction and sense as well as magnitude. This in itself indicates that momentum is not likely to be a suitable analogy for entropy. It should be noted that in the elementary development of Boyle's law on the basis of the kinetic theory of gases, the *square* of the velocity is involved because not only momentum enters but also the time taken by a molecule in travelling across the cubical enclosure.

The argument drawn by Campbell in favour of his suggestion from the expression $\frac{1}{2}CV^2$ for electrical energy is not convincing, and is possibly misleading. The more fundamental formula is $\frac{1}{2}QV$, where Q is quantity of electricity and V is potential. This form suggests that Callendar was right in linking entropy to "matter of heat" as the equivalent of Q, while V corresponds to temperature.

Newt Larvæ in Brackish Water

The statement in Miss H. Spurway's interesting observations on the above subject[1], that it is generally believed that amphibian larvæ are not found in salt or brackish water, is interesting because the brackish 'slacks' or pools between the west Lancashire coastal dunes from Ainsdale to Formby have long been inhabited by breeding specimens of the common smooth newt, common frog, common toad, and natterjack toad. The natterjack is, of course, a well-known breeding inhabitant of brackish estuary waters; many hundreds breed at Ainsdale; and I have seen its tadpoles in the tide line salt marsh at the Dee mouth between Hilbre Point and Hoylake, Cheshire, and at other estuaries.

Incidentally, mention of the natterjack toad reminds me that a species inhabits Gilbert White's famous great pond at Wolmer, although not numerously, but he did not list it in his time.

Water Content of Medusæ

I have read with considerable interest the recent communication from Dr. L. H. Hyman dealing with the water content of medusæ[1]. My apologies are due to Dr. Hyman for having failed to refer to his communication of 1938[2] in my own contribution to Nature[3]; but when I was doing the work and also when writing up the account it was impossible for me to get hold of the proper references, since the greater part of the library has been removed from the Laboratory at Plymouth. However, the omission shows the close agreement in our independent results.

I do not propose to discuss the merits of our different methods beyond stating that, in the *displacement method*[4], the living specimens of *Aurelia aurita* were neither rinsed in distilled water nor drained, since in this method the living specimens are not removed from their environment. According to Dr. Hyman the water content of *Aurelia aurita* in sea-water of 3·2 per cent salinity was 96 per cent, while I found it to be 96·56 per cent in sea-water of the same salinity.

Reference to the figures given by Dr. Hyman in 1938[2] will show how close the agreement is between the determinations made on both sides of the Atlantic, and one trusts that the figure 99·8 per cent for the water content as originally recorded by Gortner[5] can now be allowed to sink into obscurity and no longer find its way into current text-books either of an advanced or elementary nature. One would expect the water content to vary slightly in different specimens, but its value lies between 96 and 96·6 per cent, and it varies slightly with the salinity.

Further, in medusæ living in water of more than 3 per cent salinity, the water content ranges from 94 to 96·6 per cent. In freshwater medusæ it may be higher. 99·8 per cent is clearly an impossible figure for the water content of any animal living in ordinary sea-water, though admittedly such an animal might be composed of 99·8 per cent *sea-water*.

A Middle Pleistocene Discovery in the Anglo-Egyptian Sudan

Artefacts in type similar to the Chellean, early Acheulean, and Acheulean of the fourth stage of East Africa have been found *in situ* in ironstone gravel only 5 m. above the present flood plain on the banks of the Khor Abu Anga, a left-bank tributary which joins the Nile a kilometre downstream from the confluence of the Blue and White Niles. Late Acheulean implements and a few artefacts of Levallois type apparently associated with them have also been found on the surface; and it is hoped before long to find them *in situ* too.

Similar assemblies have also been found farther downstream on the left bank between Khor Abu Anga and the Sabaloka gorge.

These discoveries mark an important stage in the study of the history of the Nile basin. Besides showing that erosion levels had nearly reached those of the present day long before the Sebilian silts were deposited below Wadi Halfa, and that a pre-Sebilian lake extending as far as the Sabaloka hills is most improbable, they indicate the way by which further study will yield a more complete view of the history of the two Niles, and will link up the succession of events in East Africa and the Belgian Congo with those in Egypt and the Mediterranean region generally.

Evidence has also been found in favour of regarding the ironstone gravels of the district as of sedimentary detrital origin, derived from the local Nubian series. The previous view[1] that these were lateritic '*marram*' and indicated a comparatively late 'lateritic' climate is without foundation[2], as no trace of general 'lateritization' of the included boulders or artefacts can be found, nor is there any lateritization of subjacent deposits, whether rock (Nubian series) or gravels and sands.

EVOLUTION OF WIRE TELEPHONY

GEORGE H. GRAY, writing in *Electrical Communication* (20, No. 4; 1942) gives a brief historical review of the progress achieved in telephone wire transmission systems since the early days of the telephone, followed by a discussion of the important economic implications of the newer broad band systems, the 12-channel carrier and coaxial cable. The review is divided into four periods. Plant additions permitted advances during each period in at least three of the following respects: conversation distance, transmission channels obtainable from a pair of conductors, frequency band transmitted and, hence, improved quality and naturalness of conversation, and reliability of service.

The first period, dating from 1876, ended about 1900. Although conversation then was virtually still limited to one per pair of wires, reliability of service and transmitted quality had been improved and the transmitting distance increased considerably, due largely to the use of copper instead of iron wire, better insulators, improved line construction and carefully designed transposition schemes. These changes involved no additions to the inside plant and no increased complications in the outside plant other than the necessity for properly maintaining the transpositions. Using 4·19 mm. copper wire, conversation under favourable conditions was possible by the end of this period over distances of nearly 1,600 km.

The second period, from 1900 to about 1915, saw the introduction of phantom circuits, loading coils and quadded toll cable. These changes resulted in a 50 per cent increase in the circuit capacity of a pair of wires and in slightly more than doubling the transmitting distance of open-wire circuits. The use of underground toll cable, of course, improved the reliability of service. Loading, however, limited the frequency band which could be transmitted, and in some cases this was confined to frequencies below approximately 1,800 cycles, affecting the quality of the transmission accordingly.

The introduction of loading coils also reduced the speed of transmission, thus bringing about potential difficulties from transient and echo effects; this was not particularly objectionable at the time as the circuits involved were comparatively short. The inside plant was made slightly more complex by the phantom repeating coils, and the loading made necessary certain precautions in the maintenance of the outside plant. In general, however, this period added little to plant complexity.

The third period, 1915–37, included the introduction of some radically different and very important types of plant, such as the vacuum tube repeater, the four-wire circuit, one- and three-channel carrier systems, and radio links.

During the last few years of the second period, interesting service results had been obtained with 'mechanical' repeaters, consisting essentially of combination microphones and telephone receivers, but this was abandoned soon after the advent of the vacuum tube repeater. The latter at once more than doubled the transmitting distance of open wire circuits and, by making possible the removal of open wire loading, permitted the transmission of an increased band width. In cable circuits, repeaters permitted a reduction in the weight of loading and hence an increase in the band width and speed of propagation. The four-wire circuit greatly increased the transmitting range for cable. The three-channel carrier made it possible to obtain nine circuits from an open wire phantom group where only three could be obtained before. By combining transoceanic radio links with land circuits, the transmitting range was increased to such an extent that a conversation around the world was held in 1935 over the route New York–London–Amsterdam–Java–San Francisco –New York, approximately 36,000 km. These advances were not obtained without an increase in the complexity of the plant. It became necessary to maintain repeaters, carrier terminal equipment, radio terminal equipment, special transposition schemes, etc., but, on the whole, no very serious difficulties were encountered. This was due, in no small measure, to special plant personnel training courses conducted at appropriate intervals.

Thus, vacuum tube repeaters and three-channel open wire carrier systems made possible a practically unlimited increase in transmission range and an improvement in transmission quality. Their introduction, moreover, influenced toll-rate decreases appreciably, although outside plant expenditures remained a fairly large factor in the cost of furnishing toll telephone service. Consequently considerable attention was devoted to possibilities of further reductions in outside plant costs.

With near-zero-equivalent circuits already available on conductors approaching the minimum size imposed by mechanical limitations, the most promising solution seemed to be a further increase in the number of circuits obtainable per pair of wires. This involved an increase in the frequency band transmitted and, unfortunately, greater transmission losses and cross-talk due to the application of higher frequencies.

The negative feedback repeater, special transposition schemes for open wire lines, the separation of the 'go' and 'return' conductors in cables, special entrance cables, very careful balancing of all circuits, improved filters, dry metallic modulators, and demodulators, and many other developments made possible the application of higher frequencies to existing types of plant and paved the way for the next period in the history of wire transmission systems.

The fourth period, now well initiated, commenced about 1937 and may be designated as the 'broad band' period of wire transmission. The more important developments include the twelve-channel open wire carrier, the twelve-channel cable carrier and the coaxial cable. Although definite predictions would be somewhat premature, present indications are that progress during this period will exceed even that of the previous period.

Loading performed an important service in improving transmission, but the necessity for transmitting a wider frequency range at higher speeds has now brought about its abandonment for the highest grade of circuits in both open wire and cable.

In the case of twelve-channel systems, it might be thought that elimination of loading and the necessity for frequencies up to 60 kc./s. would prevent their commercial application. Actually, however, attenuation of 1·29 mm. conductors in twelve-channel cable systems is about 2·6 db./mile at 60 kc./s., a value which is quite admissible since it is practicable in this case to work the channels at an attenuation of approximately 60 db. per section with repeaters spaced at intervals of about 35 km. Development of these repeaters has progressed to a point where about two out of every three repeater stations generally can be operated unattended.

The reasons for this high permissible attenuation are very low outside interference at high frequencies and the use of separate cables for the two directions, or, alternatively, a single copper-screened cable to reduce interference between the go-and-return channels. The limit of amplification, or attenuation, is determined by the signal-noise ratio; low outside interference and low cross-talk result in decreased noise. Speech or transmission signals, therefore, may be correspondingly reduced; that is, very high level differences between the beginning and end of a cable section are permissible.

An inherent advantage of twelve-channel systems, highly significant from an economic point of view, results from the importance of installing cables sufficiently large to provide adequately for future growth. Since cable cost represents the greater part of the total outlay for a non-carrier system, the initial investment in cables is ordinarily great, and full realization of returns must be deferred until they are worked at full capacity. In twelve-channel systems the initial investment, on the contrary, is relatively low, and terminal equipment can be added when required; moreover, a better balance between outlay and revenue can be attained over the entire period of use.

It should be emphasized that no attempt was made to reduce the width of the frequency band when the number of channels was increased. Long experience and extensive research have demonstrated the importance of transmitting a relatively wide frequency band. A wide band width, moreover, makes it possible to reduce the transmission level, especially if the noise is low, while if the transmission loss in a long-distance link is reduced to zero, the total allowable losses can be concentrated in the local networks with considerable decrease in their cost. Further, this loss may be increased by several decibels for the same overall effective transmission if the width of the transmitted frequency band is adequately increased. To derive the full benefit from the widening of the band, the subscribers' apparatus—transmitter and receiver—must be capable of producing and reproducing this band; such apparatus has been developed and introduced into commercial use.

The propagation velocity over twelve-channel cable systems is instantaneous for all practical purposes. Even on the longest lines, therefore, speech quality is not appreciably diminished by echoes or other phenomena due to low propagation speed, and therefore lines may be interconnected at will.

Because of the advantages of the twelve-channel carrier cable system, the General Post Office in Great Britain immediately adopted it for its principal toll networks, and the first of such systems was installed in England even before the close of 1936. Shortly thereafter systems were installed in other countries, including the United States, France, Rumania, Sweden, Finland, Holland and Belgium.

For use where very large numbers of telephone circuits were needed and for television, which requires cables capable of transmitting a frequency band of at least 2 mc./s., consideration was given to the application of coaxial cables, the speech channels of which are counted in hundreds. Even for cables of small diameter, frequencies of the order of several megacycles per second can be handled and, since telephone channels are spaced at 4 kc./s., several hundred voice channels can readily be made available.

In Europe, coaxial cables have been laid in Great Britain, France and Germany. In the United States, a 150 km. cable containing two 6·7 mm. coaxial lines has been installed between New York and Philadelphia and another four-line 300 km. coaxial cable recently was placed in commercial telephone service between Stevens Point, Wisconsin, and Minneapolis, Minnesota.

The external conductor, at least above 50 kc./s., serves as a very effective screen against external interference. Hence, very low signal levels, permitting attenuation of 45–60 db. per section between repeaters, are acceptable. In a cable of 6·7 mm. internal diameter, intervals of about 8 km. between repeaters are thus admissible with a frequency band extending up to 3 mc./s.

In coaxial cable systems, the total attenuation for a long line is very high; for example, a 1,000 km. coaxial cable (6·7 mm.), capable of transmitting a frequency band suitable for 300 telephone channels, would have an attenuation of about 4,500 db. Since reception levels must be maintained within about ±1 db., repeaters must have a high degree of stability, and the net result is a permissible tolerance of about 0·01 db. per repeater. Furthermore, from the point of view of distortion and noise, these repeaters must meet stringent requirements. A very satisfactory solution is provided by the application of feedback repeaters.

The attenuation of the cable itself, either of the coaxial or twelve-channel type, varies with temperature, so that very long circuits, especially if in aerial cables, necessitate the introduction of compensation devices. For underground cables, manual compensation may be used; for aerial cables, automatic compensation is required due to more rapid temperature fluctuations. Recently a simplified regulating method using devices known as 'thermistors', the resistance of which varies with temperature in the required manner, has been developed and is expected largely to replace the former rather complicated mechanism.

Although the new transmission systems available in this fourth period of development make use of apparatus which at first glance may appear complicated, there seems to be no reason, based on extensive experience to date, to expect any more serious reaction from their application than was encountered with innovations during the other three periods.

The coaxial repeaters, especially, do not require auxiliary equipment. Furthermore, they may be installed in small, simple structures, or be enclosed in metallic housings placed on poles or in underground chambers. The relatively large number of repeaters necessary is no cause for concern. Experience has demonstrated conclusively that the manufacture of repeaters involving minimum risk of breakdown is a practical proposition; in addition, arrangements are such that either an individual repeater or a complete cable and repeater section may be replaced automatically by a reserve repeater or a complete reserve section.

The new systems represent a most important advance in long-distance communication engineering. Moreover, their development has progressed to the point where they can be considered commercially stabilized to the extent that no radical modification in the structure of cables, repeaters or terminal equipment is to be anticipated. It therefore seems evident that such broad band systems can confidently be taken as the basis for studies of new networks, affording possibilities of rate reductions and of effecting an extraordinary development in high-quality long-distance telephone communications. Further, their advent makes practical, in many instances, provision for the introduction of television networks on an international scale.

Advances during the first two periods were effected largely with material and apparatus placed in the field, that is, 'outside plant'; those of the third period depended largely on central office equipment. While an important element in progress during the fourth period doubtless must be credited to central office equipment, such as the terminal apparatus for the coaxial and twelve-channel systems, it appears that a new essential factor will be the adaptation of apparatus heretofore regarded as central office equipment to utilization in the field. This new apparatus, as previously indicated, has been embodied in unattended repeater stations.

ASSOCIATION OF UNIVERSITY PROFESSORS AND LECTURERS OF ALLIED COUNTRIES

GENERAL MEETING

THE Association of University Professors and Lecturers of Allied Countries in Great Britain marked its third general meeting with a whole-day session on December 16. The Association, which now comprises 230 members, works through twelve sections (see NATURE, December 12, p. 692), most of which had separate meetings, followed by a general meeting of all members. At this general reunion, reports were presented by the chairmen of groups of sections, and general recommendations made. Thus the deliberations of the individual sections were brought together, to present an inter-Allied view on matters in different domains of actual knowledge. Complete liberty of academic thought and spirit, with such freedom of speech as would be impossible in the countries of continental Europe, characterized the proceedings.

The main points of the aims and work accomplished by the groups of sections were as follow:

Arts: Law, economics, humanities and history, such as studies of comparative law; the position of economic science in the different countries; establishment of a scientific basis for economic planning; the possibility of reaching an agreement on the question of general history; and considerations relating to an international language.

Science: Inter-Allied collaboration for the establishment of an international academy of medicine; the establishment of an international body of information, and the co-ordination of inventions and scientific discoveries in general; an international research centre; collaboration with the Leith-Ross Committee; the establishment of liaisons with British organizations which are studying the planning and reconstruction of Europe; the examination of problems concerning the moral and material sustenance of scientific men in comparison with the manual worker.

General: Dealing with general subjects and with questions of general interest for university men; for example, contacts between British and foreign scholars in Great Britain during the War; the promotion of international collaboration after the War; reconstruction and planning of science and learning in the occupied countries, and the problems of the re-education of youth after the War in Allied and enemy countries.

Prof. R. Douglas Laurie, honorary general secretary of the Association of University Teachers, announced that all members of the Association of University Professors and Lecturers of Allied Countries were invited to become honorary members of the Association of University Teachers. This will lead to closer working and social unity between British and Allied professors and lecturers.

In the course of an address by the president of the Association, Prof. S. Glaser (Poland), the various steps were mentioned which the Association has so far been able to make to promote the necessary collaboration between scientific workers and other scholars of the Allied countries. The reconstruction of moral values as well as the rebuilding of institutions of all categories constitutes, he said, one of the aims towards which the Association is exerting its efforts. This is being carried out, so far as possible, with a profound sense, both spiritual as well as cultural, of the importance of European society as a whole after the War.

It was decided at the general meeting, among other matters, that a conference on a fairly large scale on education should be arranged for the early spring 1943, and a sub-committee under the chairmanship of Sir Alfred Zimmern (Oxford) has been appointed for this purpose.

In NATURE of December 12, a list was given of the general officers and chairmen of sections of the Association. The following can now be added to the list. Section 3: Reconstruction of science and learning in the occupied countries (*Chairman:* Mr. Willard Connely). Section 9: Medicine as distinct from general science (*Chairman:* Dr. Jean-Edouard Bigwood). Section 10:, Technical Science and Engineering, has been placed in Section 6 (Science).

Thanks to the efforts of the Association, very useful collaboration between members in the field of learning and scientific research is being established among the various professors and lecturers of the Allied countries. It provides an opportunity of establishing unity in the true sense of the word, namely, with intellectual and moral solidarity; a fact the importance of which will be appreciated by scientific men and other scholars of the Allied countries, wherever their interests in the plans and problems of to-morrow may lie.

THE WAIRARAPA (NEW ZEALAND) EARTHQUAKE OF JUNE 24, 1942

A PRELIMINARY report on some of the seismological aspects of the Wairarapa earthquake of June 24, 1942, has been issued by the Department of Scientific and Industrial Research, New Zealand (*Dominion Observatory Bull. S*-66, Wellington, New Zealand, September, 1942).

Following a rather strong fore-shock at 8.14 p.m. on June 24, the major shock occurred without further warning at 11h. 16·5m. p.m. (New Zealand Daylight Saving Time). Considerable damage to old or poorly constructed buildings occurred at Masterton, where the intensity appeared to be 8+ on the Rossi-Forel scale. There were no fatal casualties, though minor injuries were caused by falling debris. Intensity 8 on the Rossi-Forel scale was attained over a large part of Wairarapa, and the intensity in Wellington City was between 7 and 8. There was evidence of surface faulting at a point 8 miles east of Masterton, and running from a point about 10 miles north-north-east of this point to about 30 miles south of it.

The area over which the shock was felt extended from about Auckland in the north to Dunedin and Queenstown in the south, the latter place being 470 miles from the epicentre. The epicentre, determined from seismographic evidence and supported by field evidence, was near lat. 40·9° S., long. 175·8° E. The focal depth was probably normal. Earthquake sounds, usually low rumblings, and luminous phenomena, usually blue or green flashes, were reported from numerous places in both islands.

Up to June 30, 418 aftershocks were recorded by the seismographs at Wellington, 300 of these being within 24 hours after the main shock. None of these shocks was a large one, but on August 2 at 00h. 34m. a.m. N.Z.D.S.T. a shock nearly as severe as the initial one occurred. Some further damage was caused, chiefly to buildings previously damaged, and occasionally to buildings repaired after the first shock in which the mortar had not had time to harden.

The Wairarapa district has been shaken previously by earthquakes on March 5, 1934, August 6, 1917, April 12, 1913, August 4, 1904, and in 1855, epicentres not always being in the same place.

FORTHCOMING EVENTS

(*Meetings marked with an asterisk are open to the public*)

Tuesday, February 23

Royal Anthropological Institute (at 21 Bedford Square, London, W.C.1), at 1.30 p.m.—Dr. I. Zollschan: "How to Combat Racial Philosophy".

Royal College of Physicians (at Pall Mall East, London, S.W.1), at 2.15 p.m.—Dr. S. A. Henry: "The Health of the Factory Worker in War Time" (Milroy Lectures, 1).

Chadwick Public Lecture (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 2.30 p.m.—Prof. M. Greenwood, F.R.S.: "Social and Industrial Environment and Disease".*

Manchester Literary and Philosophical Society (in Room No. 7, The University, Manchester), at 5 p.m.—Dr. J. H. Shaxby: "The Human Senses, especially Sight and Colour Vision".

Institution of Civil Engineers (Railway Engineering Division) (at Great George Street, Westminster, London, S.W.1), at 5.30 p.m.—Mr. A. S. Quartermaine: "Railway Construction in Great Britain under War Conditions".

Wednesday, February 24

Royal Society of Arts (at John Adam Street, Adelphi, London, W.C.2), at 1.45 p.m.—Mr. P. E. Cross: "Agriculture To-day and To-morrow", 5: "Extension of Market Gardening into Agriculture".

Thursday, February 25

British Society for International Bibliography (at the Science Museum, Exhibition Road, South Kensington, London, S.W.7), at 2.15 p.m.—Annual General Meeting. Mr. E. Lancaster-Jones: "The Operation of a Microfilm Service". Symposium on "The Classification of Maps and Plans for Territorial Planning" (to be opened by Mr. E. Carter).

Royal College of Physicians (at Pall Mall East, London, S.W.1), at 2.15 p.m.—Dr. S. A. Henry: "The Health of the Factory Worker in War Time" (Milroy Lectures, 2).

Friday, February 26

Royal Institution (at 21 Albemarle Street, London, W.1), at 5 p.m.—Prof. L. P. Abercrombie: "The Inter-Action between Town and Country Planning".

Chemical Society (in the Lecture Theatre of the Chemistry Department, University College of North Wales, Bangor), at 5.30 p.m.—Prof. T. P. Hilditch, F.R.S.: "Some Aspects of the Chemical Constitution of Milk Fats".

Chemical Society (Joint Meeting with the University Chemical Society) (in the Chemical Lecture Theatre, The University, Sheffield), at 5.30 p.m.—Prof. J. M. Gulland: "Aspects of Nucleotide Chemistry" (Tilden Lecture).

Saturday, February 27

Malacological Society (at the Linnean Society, Burlington House, Piccadilly, London, W.1), at 2.30 p.m.—Annual General Meeting and Commemoration of the 50th Anniversary of the Society's Foundation.

Light Railway Transport League (at Fred Tallant Hall, Room J, Drummond Street, London, N.W.1), at 3 p.m.—Dr. Hugh Nicol: "A Scientist Looks at Transport".*

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Assistant Master to teach Mathematics, with some Physics or Chemistry, in the Sheffield Junior Technical School for Boys—The Director of Education, Education Office, Leopold Street, Sheffield 1 (February 24).

Lecturer in Electrical Engineering—The Clerk to the Governors, Heanor Mining and Technical School, 30 Mansfield Road, Heanor, Derbyshire (February 24).

Teacher (man) of Physics in the Junior Technical School—The Principal, Technical College, Church Street, Barnsley (February 26).

Chair of Mining—The Secretary, The University, Edmund Street, Birmingham 3 (March 1).

Instructor in Beekeeping—The Education Officer, County Hall, Wakefield (March 1).

Assistant with knowledge of Russian, German and other European Languages—The Deputy Director, Imperial Bureau of Animal Breeding and Genetics, King's Buildings, Edinburgh 9 (March 5).

Master to teach Mathematics and Science in the new Junior Technical School Building Course for Boys, Bingley Technical School—The Divisional Education Officer, Education Offices, Bingley, Yorks. (March 7).

Sir Dorab Tata Reader in Pharmaceutical Chemistry in the Department of Chemical Technology—The Registrar, University of Bombay, Bombay, India (April 15).

Teacher of Engineering Workshop Practice and General Engineering Subjects in the Burton-on-Trent Technical Institute and Junior Technical School—The Secretary and Director of Education, Education Offices, Guild Street, Burton-on-Trent.

Research Assistant—The Director, Research Association of British Flour-Millers, Old London Road, St. Albans, Herts.

CENTENARY OF THE HOUSE OF MACMILLAN

THE House of Macmillan, as a publishing firm, is a hundred years old. Daniel and Alexander Macmillan founded the firm in 1843, and their first two books, A. R. Craig's "The Philosophy of Training" and W. H. Miller's "The Three Questions: What am I? Whence came I? Whither do I Go?" were published during that year.

Birth and Growing Pains

Daniel and Alexander were both sons of Scottish peasants. Daniel was born in the island of Arran on September 13, 1813; but the family migrated to Irvine, on the opposite coast, when Daniel was three years old. Daniel eventually went to Glasgow where he made several faithful friends, such as Dr. George Wilson, the technologist and author of the "Five Gateways of Knowledge", and Mr. J. MacLehose, who eventually became Glasgow's leading bookseller and publisher, and whose firm to-day is the Glasgow University Press, with whom the House of Macmillan still enjoys happy collaboration. Indeed, Daniel was very fortunate in his friends, and the fruits of such friendships are still being garnered by the present-day firm and the public it serves so well.

In 1833, Daniel came to London. He joined the firm of Simpkin Marshall, but was not content there. He spent some time considering going to Cambridge after failing to obtain a post with the publishing firm of Longman. It is just as well at this stage to examine the character of one of the two most important founders of this great firm. Before leaving London, Daniel decided to see the sights; his letters to various relatives and friends bring out the character of the man. For example, in a letter to his brother William, written on September 30, 1833, he says:

> "The top of St. Paul's. What a sight. To see all London, even its highest spires, under one's feet, to think of the many thousand souls that are busy in that mighty mass of brick; the number of sailors who are now busy among yon forestry of masts; the numbers who are dying; the numbers who are just entering upon life. To think of those who are enduring pain, and those who are enjoying pleasure; of the villains and the saints; the active and the indolent: the virtuous and the vicious: the pious and the profane: the prodigiously rich and the miserably poor: the noble and the mean, who inhabit or infest that marvellous and mighty place, improving or injuring its morals, saving or destroying its souls. It is awful beyond description. I can hardly bear it."

Daniel Macmillan was a man who admitted to and performed a mission in life, a man who recognized a debt to society—a very practical sociologist. And like all such individuals, he was impetuous beyond belief. His impetuosity remained with him to the day of his death on June 27, 1857, when, as Thomas Hughes, author of "Tom Brown's School Days", wrote of him: "In a few hours the impetuous spirit was at rest". Here we had a man who, in his impetuosity, was striving to give something to the world, and who, therefore, like his brother Alexander, did not miss his greatest chances in life by wasting time calculating what he himself was to get out of it. Those who, under the cloak of service to humanity, are really seeking self-aggrandizement (and such exist even in the scientific world) might with profit study the lives of such people as the founders of the House of Macmillan.

Cambridge Days

At Cambridge, Daniel Macmillan joined Mr. Johnson, a bookseller, but three years afterwards, in 1837, he left again, having made many friends, some of them rising men in the University. Later, he came to London and entered Messrs. Seeley of Fleet Street, where he was joined by his brother Alexander in 1839. Alexander was five years younger than Daniel, and was a village schoolmaster near Paisley when he left Scotland for London.

After working very hard against considerable poverty, the two brothers, in February 1843, were able to claim independence and they opened a shop in Aldersgate Street, London, with little or no capital to back them up. However, on the advice of Archdeacon Hare, whose reputation at Cambridge was then at its height, the Macmillan brothers transferred their business to Cambridge towards the end of 1843, and there, until Hare's death on January 23, 1855, both brothers, especially Daniel, came under the influence of the Archdeacon.

Daniel married Francis Orridge, daughter of a Cambridge pharmaceutical chemist, on September 4, 1850. Their first boy, Frederick (afterwards Sir Frederick), was born in 1851, and the second, Maurice, in 1853.

The Cambridge book-selling business of the Macmillans flourished in spite of Daniel's ill-health and the firm's lack of sound financial backing. The success was probably due initially to the peculiar experience and whole sympathies of Daniel, and to the enthusiastic support of Archdeacon Hare. Both brothers established good relations with the University undergraduates. As one of their earliest customers wrote:

> "When the Macmillans first established their shop in the heart of the University, on a well-chosen site opposite the gates of the Senate House, the undergraduates felt that with men hardly older than ourselves there was opened to us a new sphere of interest. They were the first booksellers whom I, for my own part, had ever known to take an enthusiastic interest in their business and to have a literary insight below the binding of their books."

Thus the Macmillans gained and developed the confidence of the university men—undergraduates and authorities alike. Writing to Thomas Hughes of Daniel Macmillan, the then Headmaster of Uppingham said:

> "He stands out in my memory perhaps the most distinct personality of my early manhood—the embodiment of gentle, thoughtful power, which attracted one exceedingly, and lives with me still."

Among the regular visitors to the Macmillans' shop were the 'Olympian Thompson', W. G. Clerk, the mathematicians Todhunter and Barnard Smith, and the three great Cambridge scholars, Westcott, Lightfoot and Hort. Alexander was also a close friend of Clerk Maxwell.

Congratulations and encouragement were now pouring in on the young brothers, so that within the first year at Cambridge, the possibilities of a publishing business of their own crept into Daniel's mind, though the smallness of the capital of the bookseller's shop kept the brothers in constant anxiety. However, after bringing in a succession of partners, capital increased, and in 1845, Daniel was at last convinced that the chance of growth for the business lay in the direction of publishing more than bookselling. The advantages which their position at Cambridge, a great literary centre, gave them had become more and more apparent. Here was a mine, hitherto almost unworked, for the best book-producing power, especially of educational books.

Thus Daniel and Alexander Macmillan, although they had to date published only a few works, turned seriously to publishing, and from the very first established and maintained contact with the best writers and editors, especially among the Cambridge men. The close liaison which they developed between themselves and their authors may be illustrated by the following quotation from a letter written by Daniel Macmillan to Charles Kingsley, commenting on the latter's sketch of his projected "Westward Ho !"

> "We are greatly taken with all you tell us about the plan and character of your novel. Of course you will not adopt that pseudo-antique manner in which *Esmond, Mary Powell*, &c., &c., are written. That style is now getting a bore. The free march of your own style will be much more Elizabethan in manner and tone than any you can assume. We feel sure it will be a right brave and noble book, and do good to England."

A further comment he wrote on Kingsley's proposed "Wonders of the Sea Shore" is so amusing as to deserve quotation here:

> "We don't think it will pay to give copies to the country papers. The rascals sell and lend books, and do more harm than good."

During the first period of publishing, lasting for several decades, most of the Macmillan books were in keeping with the then public and academic taste on theological or moral philosophical themes.

Daniel Macmillan died at the very early age of forty-six on June 27, 1857, leaving three sons and one daughter. Two of his sons, Frederick and Maurice eventually became directors of the firm. It was therefore left to his older brother, Alexander, to develop much of the educational side of the Macmillan business and to sow the seed which eventually grew and ripened into the products which academic and other reading men know so well to-day. Alexander's devotion to F. D. Maurice, the leading Cambridge divine, Archdeacon Hare, Hort, Charles Kingsley, and his affection for Matthew Arnold, John Morley, T. H. Huxley and W. K. Clifford were great assets in helping him to keep in touch with all branches of scholarship in those days.

He, too, like his brother, though deeply religious, was far from being intolerant. This is well illustrated in a letter he wrote to Tennyson, in which, referring to Darwin's "Origin of Species", which had just been published, he said:

> "I wish someone could bring out the other side. *But surely the scientific men ought on no account to be hindered from saying what they find are facts*" [italics ours].

The discussions on Darwin's recent publication at one of the Macmillan famous Thursday Evenings held at the Covent Garden premises must have been full of inspiration and have given much food for thought, for such worthies as Huxley, Kingsley, Maurice, Hughes and Masson contributed to them.

Alexander died on January 26, 1896. His son, George, eventually became another director of the firm.

Return to London

In 1858, a London branch of the firm had been opened in Henrietta Street, Covent Garden. Then, the remarkable expansion of the business had made it imperative to move the headquarters to London in 1863, and the firm remained in Covent Garden until 1897, when it built its own fine premises in St. Martin's Street, which it still occupies.

Tracing the period from that date to the present day, it is interesting to note that family continuity in the direction of the business has been maintained to a considerable degree. Sir Frederick Macmillan and Mr. Maurice Macmillan, sons of Daniel, and Mr. George Macmillan, son of Alexander, actively directed the firm until their deaths in close succession to each other in 1936. Since then, Mr. Daniel and the Right Hon. Harold Macmillan, sons of Maurice, and Mr. William Macmillan, son of George, have been chairman, vice-chairman and director respectively.

To-day the influence of the House of Macmillan has extended itself to all parts of the world where books are published or eventually find their way. The Macmillan Company of New York, originally founded by the British firm in 1869, has developed into one of the most important publishing houses in the United States. Although now under independent management, it works in close co-operation with the British company. The Macmillan Company of Canada was established in Toronto in 1906, and now occupies a leading position in the Canadian publishing world. The parent British firm has connexions all over the world, publishes books in many different languages, and has three offices in India and one in Australia.

The modern reader of general literature associates the name of Macmillan with such distinguished authors as Rudyard Kipling, Lewis Carroll, Thomas Hardy, W. B. Yeats, Hugh Walpole, Rebecca West, James Stephens, Pearl Buck, James Hilton, Osbert Sitwell, Mazo de la Roche, to name only a few of the best-known figures in their list. Among the well-known periodicals it publishes are the *Economic Journal*, the *Round Table*, the *Nursing Times* and NATURE.

The firm's activities, however, cover the whole range of literature, history, philosophy, economics and sociology, as well as scientific and technical treatises and all classes of educational books from those suitable for nursery schools to well-known university texts.

Readers of NATURE will be especially interested in the Macmillan scientific and educational publications —those solid, dependable works, the most successful of which go through edition after edition, and, unlike most fiction which is of an ephemeral nature, remain on the catalogue for decades. These scientific, educational and other works of scholarship have proved to be the backbone of the firm, and a brief review of the development of Macmillans along these lines may give some insight into the *raison d'être* of the present firm as one of the leading British publishers of educational books and periodicals.

"NATURE"

The idea of a weekly journal of science began in 1868 with discussions between Sir Norman Lockyer, the astronomer and spectroscopist, and his friends, among whom were Alexander Macmillan. Lockyer was assured of the support of T. H. Huxley, Tyndall and practically all the other leading workers in science of the time. Alexander Macmillan enlisted the support of Sir Joseph Hooker and other of his scientific friends; but much of the initial success was due to Alexander Macmillan himself, of whom Sir Norman Lockyer once wrote:

> "It was in consequence of his sympathy and enthusiastic assistance that the journal started. He was unwavering in his support of the belief that British science would be advanced by a periodical devoted to its interest. . . . It was the hope that a more favourable condition for the advancement of science might be thereby secured that led Mr. Alexander Macmillan to enter warmly into the establishment of *Nature* in 1869."

In this connexion we might quote part of a letter written by Alexander Macmillan to Sir William Thomson (afterwards Lord Kelvin):

> "Lockyer is going to start a weekly Journal of Science, which we are to publish. It is meant to be popular in part, but also sound, and part devoted specifically to scientific men and their intercourse with each other. Huxley, Balfour Stewart, Wilkinson, Tyndall, Roscoe and almost everyone who is about London have given him their names, and he very greatly wishes yours, as among those who promise support. May I tell him you consent ?"

The launching of NATURE is chronicled in a letter to the Glasgow bookseller, MacLehose, written on November 3, 1869 :

> "*Nature* is to be published on Thursday in London at 2.30. . . . Lockyer was peremptory that our publication day should indicate the point to which our information is brought up. The fallacy of a Saturday publication with a Thursday actual information he does not think right. . . . We start with 18 pp. of advertisements. . . . I think it will look nice."

In the complete context of this letter it is worth noting that Sir Norman Lockyer had an absolutely free hand in reviewing books published by the firm of Macmillan itself, and never hesitated to criticize them adversely if he thought they deserved it. This absolute and complete freedom of policy has been extended to the editors of NATURE from that day to this.

In 1919, Sir Richard Gregory succeeded Sir Norman Lockyer in the editorial chair of NATURE. During his long period of editorship the journal made considerable progress, and its influence in the world of science has gradually become stronger and more secure. To-day it is the leading journal of science. In 1938, Sir Richard Gregory was succeeded jointly by Mr. A. J. V. Gale and Mr. L. J. F. Brimble. The extent to which NATURE has now grown, not only in scientific but also sociological influence, must be left to the opinion of its readers.

One thing, however, we think that readers of NATURE should know is the great debt which they owe to the publishers. NATURE was initially launched and is still being published almost solely for the advancement of science, in spite of the fact that it is privately owned by a business firm. The present editors feel impelled to put on record their gratitude to the present directors of the House of Macmillan for the entirely free hand given them in guiding the policy of NATURE and in deciding what shall and what shall not be published. To-day, as much as ever, if NATURE feels that in the interests of science and culture, any book, whether published by Macmillans or not, should receive adverse criticism, then it gets it. If NATURE desires to follow a certain policy where science is concerned, whether it be against or in support of other authorities, even the Government, then her policy is pursued relentlessly, yet, we hope, with tolerance. The directors never interfere with policy. Rather do they encourage the journal in all manner of ways, some of which have not received the recognition in the past that they deserved. In fact, it is quite possible that had the former directors not been prepared in the interest of scientific development to publish NATURE for several decades at a financial loss, NATURE, as we now know it, might not be in existence.

To-day, financial problems do not exist, and the considerable help given during the present very difficult times (especially of paper shortage and other exigencies of war) by the directors and their staffs certainly relieve the present editors of a considerable amount of care, and thus contribute in no small way towards the advancement of science in general and the success of NATURE in particular.

Educational Books

Text-books and works of scholarship which have emanated from the House of Macmillan have been legion. There has never been anything shoddy or cheap about those publications, for the directors invariably choose their authors with scrupulous care, and having once chosen them give them every possible help towards the best production that can be obtained from a first-class author working in complete harmony with a first-class publisher. In fact, though it is obvious that some works of scholarship, especially the very advanced, can never prove to be paying propositions, that has not deterred the directors from publishing, provided they are assured that in publishing they are contributing towards the advancement of science and culture.

The first directors of the House of Macmillan established a tradition of *esprit de corps* among everyone connected with any book—author, publisher, editor, printer, and all staff concerned—a tradition which is kept very much alive to-day. Contact with authors was always of the closest, and contact and intercourse between different authors was often stimulated through the agency of the directors. This is well illustrated by the list of guests who attended a dinner at the Savoy Hotel on November 22, 1894, to celebrate the twenty-fifth anniversary of the establishment of NATURE.

Present-day readers will note the high percentage of names which have now passed with honour into the annals of scientific research, education and scholarship.

It is not necessary to give an exhaustive list of names of men of science whose text-books, treatises and theses have reached the scientific world through the House of Macmillan ; but a few of those whose names appeared in the catalogues of the first forty-odd years of Macmillans make interesting reading. Grouped under their various subjects, the following are examples :

Mathematics and Astronomy. Wilson, Todhunter, B. Smith, Christie, C. L. Dodgson (Lewis Carroll), Airy, Challis, Penrose, Lockyer, Routh.

Physics. Clerk Maxwell, Balfour Stewart, Rayleigh, J. H. Gladstone, Stokes, Oliver Lodge, Tait, Sylvanus Thompson.

Chemistry. Roscoe, Würtz, Watts, Thorpe.

Statistics. F. Galton.

Geography. S. W. Baker.

Economics. Alfred Marshall, J. N. Keynes, J. E. Cairnes, H. Fawcett.

Logic. W. S. Jevons, J. Venn.

Geology. Sedgwick, Geikie, Sabine, J. W. Dawson, Boyd Dawkins.

Biology. A. Newton, D. Oliver, T. H. Huxley, A. Russel Wallace, J. D. Hooker, Ray Lankester, H. C. Bastian, Wyville Thomson, T. J. Parker, Williamson, Gilbert White, Pasteur, Lubbock, Bower.

Medicine and Surgery. G. M. Humphry, Acland, J. R. Reynolds, W. H. Flower, Maudsley, Fox, G. Rolleston.

Education. Matthew Arnold, Dean Farrar, Thring, Sonnenschein, Meiklejohn.

Science Primers. These were some of the first attempts to bring authoritative science text-books within the reach of the schools. They began in 1872 with Roscoe's "Chemistry", and this was followed by Michael Foster's "Physiology", Geikie's "Geology" and "Physical Geography", Hooker's "Botany", T. H. Huxley's "Introductory", Jevons' "Logic" and "Political Economy", Norman Lockyer's "Astronomy" and Balfour Stewart's "Physics".

George Wilson, author of the "Five Gateways of Knowledge" and of several technological books, also figured in the earlier catalogues.

Such men of science, with the essential help of the House of Macmillan, did much towards building the tradition upon which a large number of British educational publications of to-day rest. But progress since those days has been rapid yet sure, so that among the several thousand titles in the present-day Macmillan catalogue can be found many names of first importance in the educational and scientific world.

It is doubtful whether most readers of books realize to what extent those books depend on their publishers as well as their authors. This applies more to educational texts, with graphs, tables, maps, diagrams, and so forth, than to any other type of book; and the same may be said of periodicals.

Among the present directors of Macmillans are two grandsons of the original Daniel Macmillan—Mr. Daniel Macmillan and the Right Hon. Harold Macmillan. At present, Mr. Harold's position as His Majesty's Minister in North Africa is, as one can well imagine, demanding all his attention. Mr. Daniel Macmillan is therefore shouldering a tremendous responsibility ; but well and truly is he doing it and thus carrying on the tradition established by his forebears—a staunch friend of NATURE, a keen judge of a good book, and an ardent worker for the advancement of education. In fact, those of us who have the pleasure of knowing him see much of what was clearly manifest in his grandfather. Impetuous to a degree, impatient of trivial matters, and, therefore, what usually goes with such characteristics, indefatigable in his efforts to do a grand job of work. While the House of Macmillan is able to carry on under the direction of men like the present Mr. Daniel Macmillan, NATURE and Macmillan educational policy have nothing to fear. His is a glorious heritage, and we and the whole world of science must offer him our heartiest congratulations on this anniversary.

MASS OBSERVATION OF THE PEOPLE

The Pub and the People

A Worktown Study. Mass Observation. Pp. 350. (London : Victor Gollancz, Ltd., 1942.) 16*s.* net.

MASS Observation is an organization which has been evolved to make objective studies of the way of life of the peoples of Great Britain. The sponsor of the movement, Mr. Tom Harrisson, was formerly a professional anthropologist, who, whilst working on the island of Malekula in the New Hebrides Group, came to the conclusion that the people in the wilds of Great Britain were as much in need of scientific observation as the cannibals of Malekula. On his return to Great Britain he teamed up with a newspaper reporter, Mr. Charles Madge, who was thinking along similar lines. Thus Mass Observation was born. In August 1939 it consisted of a team of whole-time paid investigators and a nation-wide group of voluntary observers providing information about themselves and their neighbours. This by way of introduction to the organization that produced this book.

For the three years prior to the outbreak of war, this group concentrated on an unnamed industrial town in the north of England, which, short of naming it, Mass Observation takes great pains to suggest must be Bolton. Four major points were considered: the role of the public house in the life of the town, politics and the non-voter, the part played by religion and the annual holiday at Blackpool. This volume deals with only the first of these issues, publication of the other three volumes being suspended for the war period.

"The Pub and the People" is neither a scientific report nor a readable collection of essays. Rather is it a collection of verbose—very verbose—superfluities, interspersed with a number of statistics, which, important though they may be, do little but substantiate empirical deductions which one would inevitably make during a period of regular pub-going. If a scientific report had been intended, this volume would not have been greater than one sixth of its present size. If the writers had envisaged a book that would appeal to any intelligent reader, the contained information should have been more carefully collated and edited.

The following are some of the more interesting facts that emerge from this orgy of words. In "Worktown", the ratio of pubs to people has decreased considerably since the Act of 1839 empowered magistrates to refuse to grant the renewal or issue of beer licences. In the pre-1939 period the pub played a smaller part in the life of the town than it ever did. (It is unfortunate that a short appendix could not have been included indicating the effects of the War on the nation's drinking habits.) As a cultural institution, the pub is a declining force. "Pools, radio, press, motor-culture, dance-halls too (to a surprising extent), cinema, do not create a social group of people sharing consciously the same experience. . . . They are slowly changing the whole aspect of England and no one seems to be noticing it." The latter part of this statement is typical of some of the sensational embellishments which clutter up this book ; this is bound up with complete disregard for objective truth. A frontal attack is made upon "the irresponsibility and ignorance of scientists", without indications of their deficiencies. Other interesting conclusions suggest that the regular pub-goer "puts away" fifteen to twenty pints of beer a week; the more people in the pub, the more quickly do individuals drink their beer; drunkenness is not necessarily dependent upon the drinking facilities available; the usual assumption that the time a pub is open directly affects drunkenness is shown to be unrelated to demonstrable fact. Above all, the main text, which occurs as often as one would expect in a bad sermon, is that the true function of the pub is that of a safety valve, a means of allowing partial release from tensions accumulated in the stress of living. With which, no doubt, we all agree.

T. H. HAWKINS.

MARVELS OF THE VERTEBRATE EYE

The Vertebrate Eye and its Adaptive Radiation

By Gordon Lynn Walls. (Bulletin No. 19.) Pp. xiv+785. (Bloomfield Hills, Mich.: Cranbrook Institute of Science, 1942.) 6.50 dollars.

LIMITATION of vision to a narrow range of wave-lengths of radiation is manifestly related to the absorption of radiant energy by protein and water. The importance of light as a directive agent is associated with a wide range of light detectors in invertebrates. As the pineal eye is relatively unimportant in vertebrates, these devices are crystallized in the two lateral eyes. These lateral eyes show a wonderful variety in structure and versatility in action. The whole subject of the vertebrate eye is discussed by Dr. Walls in his excellent book, which is a mine of information about the eyes of all sorts of vertebrates.

One of the outstanding problems is the difference between vision in air and vision in water. In the former, the difference in refractive index between cornea and air enables the cornea to exert a great effect on focusing the rays of light. In the latter, practically the whole of the focusing of light must be done by the lens. Therefore there is a general difference in the lenses of aquatic and aerial animals, those of the former being spherical and those of the latter flattened from before backwards. The case of Anableps is most interesting. These animals have two pupils. When swimming on the surface with their eyes half submerged they can see objects both above and below the surface. Through the upper pupil by the cornea and less curved sides of a pyriform lens objects above the surface can be focused on one part of the retina, while through the lower pupil and more curved ends of the pyriform lens objects below the surface are focused on another part of the retina.

When the animal is amphibious there are three possibilities. Its eye can be adapted for vision in water, its eye can be adapted for vision in air, or it may have a wide range of accommodation so that it can see fairly well in both water and air. The accommodation can be brought about in several different ways. The lens may be moved backwards and forwards, the curvature of the cornea can be altered, the lens can be compressed round its equatorial plane, the anterior surface of the lens may be made more curved by constriction of the lens by the iris, and finally the lens may become more curved due to the elasticity of its capsule on slackening the suspensory ligament by the ciliary muscles.

Adaptation to different intensities of light may be brought about by a wide diversity of processes. Diurnal, nocturnal and twilight vision are comparatively simple to accomplish. Vision in bright light is associated with the presence of cones in the retina. For dim light, rods sometimes supplemented by visual purple are used. When an animal is active in both bright and dim lights, a duplex retina with both rods and cones is present. Other devices are used to help in the process of adaptation. In some cases extreme variations in pupillary aperture are used. In other cases movements of the retinal pigment combined with movements of rods and cones occur, so that cones are exposed and rods shielded in bright light while rods are exposed in dim light. The linkage of the sensory receptor cells to ganglion cells is such that cones are best for good acuity. The action of the fovea in improving acuity is explained. Maculæ, sometimes two for each eye, are present in some species. The tapetum is recognized as a means of reinforcing the effect of weak light, thus making vision better for nocturnal animals. The pecten is said to be a means for bringing increased nutrition to the inner layers of the retina in species in which the blood supply to the ganglion cell layer is inadequate. The uniformity in number of cell layers in the retina is noteworthy. Sensory receptor cells, bipolar cells and ganglion cells are found in all retinæ. Is this uniformity due to some common physiological need, or does it indicate the stage of development of the cerebral cortex when the optic vesicles were first formed? The author considers that the original sensory receptor cells were cones, and that the rods were derived from cones. Cones are present in some diurnal animals although their phylogenetic predecessors have rods only. Dr. Walls suggests that these cones have developed from rods. Is it not possible that the power to develop either rods or cones is present in the early stage of the sense cells of any vertebrate? Visual purple has developed apparently independently in isolated species. Is it possible that there is some common feature present in many retinæ, although visual purple is produced in appreciable quantity in only some of them?

All these points and many others are adequately discussed in this volume: it is one which has been needed for some time. Where so much is excellent it may seem unnecessary to criticize details. The author considers that small multiple apertures in the closed irides of geckoes may enable them to obtain a greater depth of focus. The multiple images so produced would not be superimposed except by the action of the cornea and lens. If the openings were arranged in a circle or if the pupil were reduced to an annular opening as in Plecostonus, then spherical aberration would be reduced to a minimum. On p. 75 the author states: "No one photosensitive substance could be entirely responsible for colour vision". This statement is misleading, because colour photography is possible with a single photochemical substance. The discussion on the function of coloured oil globules in eliminating scattered light is good, but surely the presence of colour filters in front of certain cones must cause a differential stimulation, and it is difficult to imagine that this differentiation would have no effect on the animal's colour discrimination. In the domestic hen the coloured globules are such as would give rise to a colour vision similar to that of man. Is it possible that trichromatism is a necessary result of some biological factor, or is it due to some physical property of light?

The author calls his book a text-book. It should certainly be read by all biologists, including medical men, interested in visual problems. H. E. ROAF.

THE EXTREME PROPERTIES OF MATTER*

By SIR CHARLES DARWIN, K.B.E., F.R.S.

WE know a great deal about many of the fundamental properties of matter, and our knowledge enables us to assign limitations on its qualities; so that whereas improvements in materials are possible, we can assign limits beyond which it is fairly certain that these improvements cannot go. It is proposed here to examine some of the principal limitations of this kind. It is only possible to deal with a few of the chief ones, and the list will include the mechanical properties of solids, liquids and gases and some of their electric and magnetic properties.

Strength of Materials

We know a good deal by now about the forces which act between atoms. There are several rather different types of force which occur in various types of solids, and the type which concerns us here is the metallic one, since in considering the strength of materials we obviously turn first to the metals. The basic structure of a metal is a crystal, usually of one of the simplest and most symmetrical classes. In this crystal the atoms have each one or more electrons set free, and these wander about freely as a sort of cloud. This cloud of negative electricity acts as a sort of cement holding together the positively charged atoms. In addition, these atoms exert forces on one another, partly of the repulsive electric type that would be expected, but also others of a kind the principle of which is to be mastered only by going rather deeply into quantum theory. The behaviour of these forces can be imitated by thinking of atoms as exerting attractions or repulsions on one another, but these forces need no longer conform rigorously to the pure electric type. The only character of them that I need at the moment is that they are not to vary violently with the distance; that is to say, if in equilibrium one of the forces between two adjacent atoms is so and so, then if they are displaced to a distance not greater, say, than 20 per cent, this force will not have altered by more than, say, a factor of 2.

Let us now examine what we should expect for the strength of a crystal based on this model. Consider, as the most characteristic thing in a solid, its shearing strength. Fig. 1 shows two rows of atoms, each of which is intended to represent a whole sheet of atoms standing out at right angles to the paper. The sheets are held together by their mutual atomic forces together with those coming from the atoms in the sheets above *A* and below *B* which are not shown. In the unstressed condition the atoms of *A* and *B* are supposed to be exactly opposite one another, but this is unessential to the argument; the first atom of *A* would therefore be at the point *L*. Now impose a small shear by displacing the whole sheet *A* and all above it a little to the right. A force will at once come into play resisting this displacement, and we can tell what this force is by our knowledge of the shear modulus.

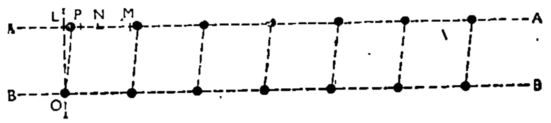

Fig. 1.

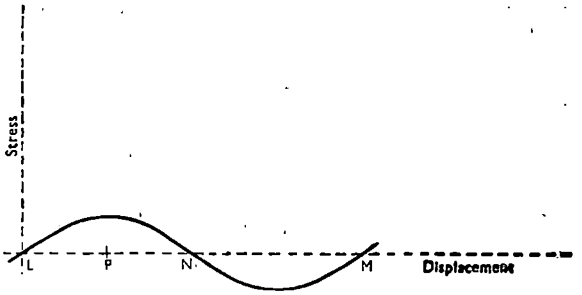

Fig. 2.

We can conveniently represent what happens by making a diagram (Fig. 2) in which the stress is plotted against the displacement of the sheet of atoms *A*, and the shear modulus gives the direction of the tangent at *L*. As to what happens farther on we cannot be sure, but we do know that if the *A* sheet is bodily transplanted one atom's length along to *M*, the force will vanish again, and around this point the curve will repeat itself. Moreover, half-way between there must be another point of equilibrium, and this must be unstable, because it lies between two points of stable equilibrium. This will be represented by the point *N* and a tangent sloping the other way. We do not know how to complete this curve, but we can make very useful conjectures about it. From all reasonable assumptions about the atomic forces being continuously variable with the distance between the atoms, we may say that the curve should have a reasonably smooth form. The simplest one to take is a sine curve, so we will adopt that. We know the slope at *L*, and the position of *N*, and from these it is elementary to calculate the height to which the curve rises at the point *P* one quarter way along from *O* to *M*. This will give the maximum stress that the metal can stand without yielding. An elementary calculation shows that this stress is $G/2\pi$, where G denotes the shear modulus. For a good steel the value of G is about 6,000 tons per square inch, and this suggests a shear strength of about 1,000 tons per square inch, in contrast to 10 tons per square inch, which is roughly the actual value.

The argument I have given suggests that a crystal of a metal ought to be very much stronger than it is; roughly it ought to be possible, without breaking, to shear a cube until it formed a parallelogram with angles given by the slope of *OP* in Fig. 1, that is to say, more than 10° off the right angle. This is completely contrary to the facts, for when a single large crystal is made of a pure metal it is found to be as soft as putty. This difficulty has been much considered, and I may refer to work of G. I. Taylor, who attributed the hardness that working gives the metal to 'centres of dislocation', that is, to imperfections in the ordering of the crystal, an effect which is practically universal in crystals. It would be out of place to go into his theory, but it confirms the point that to get a strong piece of metal one must have small crystals in it, not large ones.

If one examined the experimental facts without recourse to theory, one would conclude that it is the irregular junctions between crystals that make its strength, and that the metal is a sort of foam of these irregularities containing in its bubbles the putty-like crystals. But this is not a possible view, since we have to face the difficulty that those bubbles ought to be much stronger, by our previous argument, than the foam material between them. Moreover, there is an even greater difficulty in accepting such a view, because we know, at least roughly, the magnitudes of the atomic forces, and from them we can calculate what the shear modulus should be, and the answer comes out about right. Thus the crystals ought to be much stronger than the intercrystalline irregularities; and yet the more of these irregularities there are the stronger the metal becomes. We seem to be in the paradoxical position that a chain is strengthened by multiplying the number of its weakest links.

---

* From the James Forrest Lecture of the Institution of Civil Engineers, delivered on January 12.

Some recent ideas of Bragg and others have done much to clear up the situation. In the model I took of the sheared crystal, I imagined the atoms on each sheet rigidly held together in relatively fixed positions. In fact, however, they are not fixed, since temperature dictates that atoms can never be at rest. Each atom is oscillating all the time in an irregular manner about its average position, and this makes possible a re-adjustment among the atoms without calling into play the strong stresses which would arise if the whole sheet had to be displaced like a rigid body. Consider the matter in more detail. A piece of metal is now to be regarded as composed of a large number of small crystals, all differently oriented and held together by a cement of irregularly placed atoms. When one of the blocks of crystal several layers thick is sheared a little, the displacements of the atoms (more strictly, now, of the average positions of the atoms) will call into play reactive forces which provide the shearing stress. But if the shear is made larger a new possibility occurs, which is that a slip should occur between the two rows. On account of the heat motions of the atoms this may now occur without calling into play the violent reactions that our previous argument suggested; and to decide whether it will occur or not we adopt the obvious criterion of energy, that is to say, if the strain energy of the slipped crystal is less than that of the unslipped, then slipping will occur. This is illustrated in Fig. 3, where the form *B* will have much less energy than *A*.

The result of this argument is to explain why large metal crystals are so much softer than small, for a shear of one half the atomic distance, measured across the whole width of the crystal, suffices to produce slip, and for a thick crystal this is only a very small shearing strain. There is much else in Bragg's work beyond this which I shall not mention, but we can see how it satisfies the two important conditions, first that it is the crystals themselves that dictate the value of the elastic modulus, and secondly that it is the reduction in size of the crystals that explains the strength of the metal.

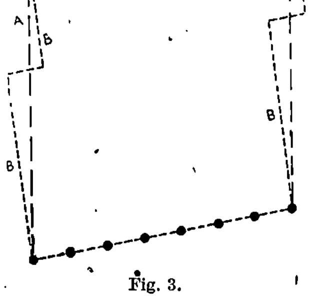

Fig. 3.

The question then arises whether we can use this theory to reduce the extreme limitation we have derived for the strength of the metal. Evidently the smaller the crystals the stronger the metal should be, but to what limit may we go? For example, if we could think of crystals only two layers thick we should be back at the earlier argument, but such a supposition would signify that nearly all the metal was composed of the irregular arrangements between crystals. An irregular arrangement of atoms of this kind is very like a liquid or a glass, and is very intractable to mathematical treatment, so that it is difficult to say what would happen from the atomic point of view. We may, however, be fairly sure that there would be some tendency to recrystallization, a sort of self-annealing, which would give rise to crystals up to a certain size, because we know that the process of annealing does tend to build up large crystals, and this tells us that the crystalline form has less energy than the glass form.

In this general connexion I would direct attention to the remarkable observations made some years ago by A. A. Griffiths, who found that a thin fibre of glass when newly made had a greatly enhanced strength. The value obtained was quite near that which would be indicated from the shear modulus as in Fig. 2, and this is most interesting as a confirmation of my general argument. With the lapse of time the fibre lost its excessive strength, presumably on account of recrystallization. Until we can know how far a similar recrystallization can be permanently prevented in a metal we cannot further reduce the extreme value we have arrived at for its strength.

As a general conclusion for the extreme limit of strength we may ever hope to attain, I therefore conclude that it is certain we cannot get beyond $1/2\pi$ of the shear modulus, and that it is most unlikely we can get beyond, say, one tenth of this—which would correspond to having crystals about ten atoms thick and to the rather unwarranted assumption that the irregular junctions would not provide a closer limitation. Since I cannot suggest any exact values for these further effects, I am going to play for safety, and take as the ultimate strength the value $G/2\pi$. This is about one hundred times as strong as existing materials.

Elasticity and Strength

Tension can be much more easily measured and tested than pure shear, and it is often more important in structures, so the engineer tends to think much more about it. I want, however, to raise the question whether tension is not really a secondary thing in the theory of the strength of materials.

The elasticity of an isotropic material has two properties which can be defined in a variety of ways: for example, by giving Young's modulus and the shear modulus, by giving one of them and Poisson's ratio, or by giving one of these three and the bulk modulus, that is, the reaction to hydrostatic stress. From any two of these the rest can be derived, and the only question is which are the best two to take? In other words, which are naturally the most primitive? A rather strong case can be made for taking the bulk modulus and the shear modulus as the two most primitive, since they correspond to the simplest types of strain which can be imposed on a solid body. In effect, this choice is made because it is easier to think of the stress as being called into play by an assigned strain, than to do what is done in a testing-machine, which is to apply a given stress and see what the strain is. If, then, we are to start with strain as given, there can be no question that a linear tension is a rather complicated thing, involving as it does both a distortion and a change of volume.

This point of view derives from the classical theory of elasticity, and it is a very tentative matter to apply it to the question of ultimate strength. In the first place, some materials break in tension and others in shear, as is easily seen from the shape of the fractured surface. The strongest materials always break in shear, and it seems likely that this is the fundamental manner. I should conjecture that breaking in tension is really a secondary business. If a bar under test contains non-uniformities there will result stress concentrations, and it is the shearing at these concentrations that causes the break. This is only a conjecture, but it leads to the plausible consequence that there is one cause, and not two causes, governing the strength of materials.

Now I have pointed out that the classical theory of elasticity suggests that the bulk modulus is a more primitive thing than is Young's modulus, and this suggests that we should consider what is the 'bulk strength' of materials, that is to say, the manner in which they yield under hydrostatic pressure or tensions. We can immediately answer half this question, for there is no doubt that the metal when hydrostatically compressed resists that compression strongly and shows no tendency to break under it. As to its behaviour under a hydrostatic tension we can scarcely give an answer at all, since it is impossible to apply such a system of forces to a solid. I know of only one experiment where something of the kind has been done. Joffe took a sphere of rock-salt crystal (which is cubic and not far from isotropic) and immersed it in liquid air until it was all of one temperature. He then plunged it in hot oil so that the outer parts expanded, and these parts applied a hydrostatic tension to the inside, which was still cold. The tension showed no tendency to produce cracks.

This one experiment is obviously a rather complex business, but it confirms a tentative conclusion that I wish to draw. The characters of solid matter may be divided into two types, namely, those sensitive to details of structure and those insensitive. All the elastic moduli are fairly insensitive, in that, for example, Young's modulus and the shear modulus are roughly the same for hard and for mild steels; but we know that the shear strength is sensitive. I want to suggest that what evidence there is points to the bulk strength being insensitive to structure. If this is correct, then we have the simplification of theory that we can impute the structure-sensitivity of tensile strength to the shear strength. The advantage of this point of view is that we have only *one* quantity to consider which needs close examination, while the second elastic character plays little part in the consideration of strength.

Liquids

The two main characters of a liquid are its compressibility and its viscosity. As to compressibility, there is little to be said. At one end we pass over into degrees of resistance to compression comparable with, but not so strong as, those of solids. At the other end we come up against the *critical phenomena* where liquid passes continuously into vapour, so that again there is no extreme property. Viscosity is more interesting. At one end we have highly viscous materials, such as treacle, then pitch, and then glasses which shade into plastic materials and become indistinguishable from solids. I may also refer to those highly peculiar substances which appear quite stiff but gradually become liquid on stirring, and the converse ones which are liquid, but become stiffer and stiffer as they are stirred; but the theory of these is rather obscure and I must not attempt to discuss them.

At the other end, that of small viscosity, there is much more interest in a particular substance which was discovered only a few years ago. This is liquid helium II. Helium is the substance with the lowest boiling-point of any, about 4° absolute. Liquefaction was achieved in 1908. The next thing to do was to solidify it, but for long no success was achieved, until finally in 1925 it was found that high pressure was essential, and that solid helium could exist only at a pressure of more than 20 atmospheres. But a much more remarkable thing was also found. At ordinary pressures the liquid suddenly changes its character at about 2°. Above this temperature liquid helium I is a fairly ordinary fluid, with a density of about 0·1, and with viscosity and specific heat about the same as those of other liquids. At 2° there is still no change in density or specific heat, but the viscosity drops to a very small value indeed and the heat-conductivity becomes enormous—a hundred times better than that of copper. That, at least, was how the matter appeared at first; but there was a good deal of discrepancy between the measures of various workers, and it was suspected that the viscosity was so low because in every measure turbulence had occurred, while measures of viscosity depend on using such fine tubes that turbulence is eliminated.

Later work has suggested that the matter is not so straightforward, and, in fact, that the character of the substance is not to be explained in terms of the ordinary language used for liquids; but the business is by no means clear yet. We may say, however, that a solid body could move extremely freely in helium II, and that it is practically impossible to keep bodies at different temperatures in its presence: and it has another remarkable characteristic in that the liquid can creep over any surface in apparent defiance of the laws of hydrostatics, so that if a tea-cup were filled with it, in a short time the liquid would appear in the saucer, and then on the table, and finally the level of the liquid would be the same all over whatever space was available.

Gases

When we come to gases there is little to be said, as the gas laws are very precise and admit of little variation. There are variations of equation of state near the condensation-point, but in the truly gaseous condition the only variety is in the density and the specific heat. The most interesting quantity is the ratio of the specific heats, which governs the law of adiabatic expansion and the speed of sound; this is 5 : 3 for monatomic gases, 7 : 5 for diatomic, and still lower for more complicated molecules. We can say at once that 5 : 3 is the highest ratio that could ever be possible. With regard to density, we can say quite definitely that the limit of lightness is attained by hydrogen.

But if I may extend the meaning of the word 'gas' there are much more interesting things to be said. There does exist matter which is much lighter than hydrogen. This is the electron, which has a mass

1/1840 of that of a hydrogen atom. Electron gas can have only a transient existence, because the enormous repulsive electric forces blow it to pieces at once; but we can take advantage of this transient existence in a more limited way. This is especially in connexion with *relays*, which turn a weak cause into a strong effect. In a quick-acting relay, inertia is obviously of the chief importance in making a given force produce the quickest effect. The force on a body, which in the most delicate systems is almost always electric, depends on the electric charge, while the motion depends on the mass, so that e/m is a measure of the capability of a system to act as a relay. The e/m of the electron is 1840 times as large as that of the next best system, the hydrogen atom, and proportionately again better than that of heavier substances. It is this enormous factor that is responsible for the high qualities for amplification of the thermionic valve amplifier.

We know of no reason or evidence that there is anything in the nature of a 'sub-electron', so that we have arrived now at the ultimate limitation in relaying action by the use of the properties of a transiently existing electron gas. It is true that there is something less heavy than electrons, and this is light itself, which carries energy but has no *rest-mass* at all. I have to word this carefully, because in a wider sense anything with energy has mass. But something besides light must always occur in a relay, because at some stage the light has to be acted on or to act on matter with ordinary inertia. The efficiency of a relay is that of its heaviest part, and so we cannot hope by any means to improve on the electronic valve.

Although a free electronic gas can only exist transiently in a tube, there is an extended sense in which it is of much commoner occurrence; this is in the interior of a metal. Here there is a framework of positively charged atoms to neutralize the electron charges, so that the gas can now be permanent. Such a gas has certain properties which are entirely different from those of an ordinary one, a fact which was first recognized with the discovery of the new quantum theory fifteen years ago. The molecules of an ordinary gas are moving about with various and frequently changing velocities, and the frequency of occurrence of these velocities is governed by Maxwell's law of distribution, giving the average numbers at any instant with each velocity in the form of the well-known 'cocked-hat' error law, the size of the curve depending on the absolute temperature.

The electron gas has its velocities distributed quite differently. This is because of the exclusion principle, one of the basic principles of the quantum theory. I must not go into technicalities, but the rule is that two electrons must never be doing the same thing. Thus, if one electron is at rest in the metal no other can be at rest: in an ordinary gas there is no reason why many molecules should not be at rest simultaneously. There are a great many electrons in the metal, and they comply with all the conditions of low energy and many of the higher, so that a lot of them are forced to have quite a high energy. Instead of the Maxwellian figure we get, at ordinary temperatures, a curve with a very sharp fall to zero. The speed at this break corresponds to what in the other curve would be given at a temperature of about 10,000°. To misstate it in picturesque language, the exclusion principle squeezes the electrons out of their rightful temperature; if the metal could be raised to 10,000° without melting, then for the first time the electron gas would behave something like an ordinary gas. I wish I could enlarge further on this, but it is hard to do so without going more deeply into technicalities. Moreover, my main purpose in mentioning it at all has been because I shall want to return to it in the next subject for discussion.

Density

We have already considered what is the lightest substance. It is natural next to ask what is the heaviest. Forty years ago there would have been the immediate answer, metallic osmium which has specific gravity 22, and the only saving clause would have been that there might be other unknown elements which would prove heavier. We now know that there are no unknown elements and yet we must answer the question quite differently. This is on account of certain very unexpected astronomical discoveries of about fifteen years ago. Certain stars were discovered which gave out light at a white heat and yet were very faint; they were therefore called white dwarfs. The white heat implied a high temperature, and with this temperature they had no business to be faint; their faintness could only be explained by small size, and this implied a very high density. For example, the companion of Sirius is about the weight of the sun but about the diameter of Uranus, and therefore its mean density must be about 50,000. At this density a cubic inch of the material would weigh about a ton.

The general theory of these dwarfs is understood, though no one knows yet fully why they occur, and what happens to them ultimately. Their structure is an extreme case of the electron gas in a metal. In the interior of a star the temperature is so enormous—millions of degrees—that the atoms lose most of their electrons, and this large number of electrons becomes subject to the exclusion principle. According to this principle there is a simple relation between pressure and density which is independent of temperature; it is the same relation as that which applies for the adiabatic expansion of a monatomic gas. So long as the temperature is not too high (and by high temperature I now mean something like a hundred million degrees) this relation holds and implies that under sufficiently high pressures there is no limit to the density. As in most things of this kind, the result must not be pushed too far, because we have omitted certain secondary matters which ultimately become important. But there is good reason to believe that in the deep interior of white dwarfs there are densities of something like two tons to the cubic inch—specific gravity a hundred thousand—which are maintained by pressures of the order of a million million atmospheres. It seems reasonable to hope that this is a final limitation on the density of matter.

Electrical Properties of Matter

What is the best insulator we can hope for? Here the answer is fairly definite; we already have it in the form of good transparent crystals such as quartz. The theory of insulators, as formulated nowadays, is curiously like that of conductors. The individual electrons in both are free to move about in the crystal, but the exclusion principle leads to an important difference. In the case of metals there is, so to speak, room for an electron to behave in a different way from what it is doing—not all the seats are occupied—so that it can wander about carrying its electricity with it. In an insulator there is a full house, so that when one electron shifts its place another is forced at once to take that place, and there can be no transport of electricity, and so no conduction.

There are two ways in which insulators fail. First, the surface often becomes covered with some foreign material, often merely water, which causes a leak over it. The second failure is much more interesting. One way of escaping from the rigour of the exclusion principle is to provide an electron with a good deal of energy, because then it can be 'doing something different' from the others. If a crystal, say of rock salt, is illuminated with ultra-violet light, some of its electrons absorb the light and acquire a high energy which sets them free to wander through the crystal. In this way a conductivity not unlike that of electrolysis arises. To get a perfect insulator this must be avoided, and it can best be done by keeping the crystal in the dark and, since there is always radiation due to temperature, to make it very cold will also help.

At the other end of the scale, what is the best electrical conductor ? Here also we can make a rather definite answer. The conductivity of alloys is worse than that of their constituent elements, both theoretically and in practical experience, so that we need only examine the table of the elements to see which is best. If we reckon by weight this is sodium, but others are nearly as good. But a far more important question is the temperature. The conductivity improves with cold, and tends to very high values at the absolute zero. It is not certain whether it might not become infinite, but as a general rule there seems to be a small residual resistance.

The interest of this is very much diminished by the extraordinary phenomenon of superconductivity. Certain of the elements—not by any means the best conductors at room temperature—and also some alloys and compounds, as the temperature drops, suddenly become perfect conductors ; lead does so at 4° K., so that if a current is started in a lead ring below this temperature it just goes on for ever—always provided the stock of cooling liquid lasts. This is a fascinating subject of study, not by any means cleared up yet, which possesses many of the characters of the older physics of Faraday rather than of modern atomic physics. There are, however, pronounced limitations in its practical utility because superconductivity is sensitive to magnetic fields, and fails when the field is strong, so that if too great a current is carried by a superconducting wire, that current's own field destroys the superconductivity.

Magnetism

The question of magnetism is also interesting because such great technical advances have been made in it lately. I can only touch on some parts of the subject, in particular on permeability and saturation values. Of these, the permeability at low fields is important for many purposes. The value for mumetal is about 60,000, and we may ask whether this could be increased.

According to present ideas, iron and nickel have the property of being spontaneously magnetized in small domains, and all that the external field does at first is to turn the direction of spontaneous magnetization into another direction of easy magnetization. There does not seem any particular limitation on this process, so that we can see no reason why quite a small field should not give practical saturation. Thus we know no reason why there should not be a better mumetal in the sense that the permeability for weak fields might be much larger ; but correspondingly the exciting field would have to be reduced, or saturation would ensue.

The question of magnetic saturation may be answered much more definitely, since there exists a fairly complete atomic theory. We can say that it is certain that nothing can show magnetic saturation much greater than that of iron, and it is extremely unlikely that anything will be found perceptibly better than iron. In this matter of saturation we are not concerned with the ease or difficulty with which the magnetization can be set up. In iron it is spontaneous, whereas in some substances it calls for such strong external fields that nothing like the maximum has ever been attained. There is a natural unit of magnetization, the Bohr magneton, but theory indicates that there is no reason why an atom should possess an exact whole number of magnetons. Thus iron has 2·2, cobalt 1·7, and nickel 0·6. The largest number known is in the rare earth europium, some salts of which have 10. This is in exact accord with theory, and as the theory has been applied to the whole table of elements, we can confidently say that it is no use expecting anything better. This magnetization is in the salt, where the europium atoms are fairly far separated from one another, so that the total magnetization is not very large. The europium atom is three times as heavy as the iron atom, so that even if the full magnetization could be produced in the metal, the resulting value would only be half as much again as it is for iron. That is why I said that there was very little expectation of getting anything better than iron.

Summary

I have ranged over a wide field of properties of matter, and had better summarize them in conclusion. I am going to do so in a fanciful manner by taking a structure built out of all the extreme materials I have imagined and seeing what it is like.

I propose to rebuild the ship *Queen Elizabeth.* My metal is one hundred times as strong as that used in the present ship. I do not propose to go into complicated questions of design ; for example, the tension members can be immediately lightened one hundred times, but the thrust members will have to be much enlarged tubes in order to remain stable. I see no reason why I should not build the ship with one-hundredth of the weight of material. As the ironwork weighs something like 30,000 tons in the present ship, my ship will weigh only 300 tons. Therefore, to get the displacement, I shall have to ballast it with nearly 30,000 tons before I begin to put in the cargo. I immediately think of using material from a 'white dwarf' star for this, and my ballast will then occupy about 17 cubic feet. However, I now notice that there will be technical difficulties in this way of doing things, since I should have to keep it at a pressure of one billion atmospheres and at a temperature of one hundred million degrees, so I give up this idea and fall back on ballast made of metallic osmium, of which I shall require as much as 50,000 cubic feet, say a block in the form of a cube of 12 yards side. It is time now to attend to the machinery. Presumably I shall think of putting in an atomic engine, but the trouble is that whatever the engine itself may be like, so far as I can see it will have ultimately to raise steam for a turbine, so that my engine-room will still have to be quite large. For the auxiliary machinery I will certainly take advantage of superconductivity, so that the wiring of the ship will be cooled by liquid helium; it must be made of tin or lead wire, since copper is not a superconductor. The magnets in the dynamos will scarcely be different from those already in use.

This suggests a further flight of fancy. My ship on its journeys still has to contend with the resistance of the water. Would it not be more economical to alter the composition of the sea into something less resistant? If it is liquid helium II, I can economize in many ways. I shall need no special cooling for the superconducting electric wires. I can leave out nine tenths of the ballast, since the density of the sea is now reduced to one tenth. It is possible that I can give up having an engine altogether by giving the ship a good shove at the start of the journey and receiving it on buffers at the end; I know too little about the real viscosity to judge of this.

But the end of all my plans is tragedy. On account of another of its properties the liquid helium II will irresistibly creep up the sides of the ship, over the bulwarks, across the deck, and down the companion ways, until it settles in the hold, in the effort to come to the same level inside as out. Deeper and deeper will grow the water in the hold, and deeper and deeper the ship will settle, until at last my imaginary ship will founder in the depths of the imaginary ocean.

RESEARCH IN THE NETHERLANDS INDIES*

By Dr. P. HONIG

Netherlands Economic Mission, Washington, D.C.

RESEARCH in the Netherlands Indies which tried to improve existing or developing processes was, and is, principally concerned with agriculture in all its aspects. Research in the field of mining had to do with the geological surveys of mechanical engineering as well as metallurgical and civil engineering.

Most of the progress in the Indies has been culled from experience gained in Europe; new scientific aid from Japan, other countries and even from the United States has been of limited significance, except, perhaps, in military matters.

It is not the purpose of this article to discuss medical research, although in the past fifteen years the relation between nutrition, hygiene and the health of the population has been intensified.

Research, as it has been organized in the Netherlands Indies, has to do, primarily, with agriculture and technology. Agriculture includes agrogeology, diseases (phytopathology and entomology) and the methods of planting, selection of varieties, application of fertilizers; the study of technology is directed towards improving the methods of manufacture of agricultural products.

The beginning of research work in the Netherlands Indies is seen as far back as the origin of the Botanical Gardens in Buitenzorg some sixty years ago. Without doing injustice to its former directors Teismann and Blume, or to individual explorers such as Rumphius and Junghuhn, the real beginning of systematic research began about 1880. Before that time, however, there was a separate survey of the natural wealth of the Netherlands Indies, with the idea of having a detailed summary on minerals, fauna and flora, the geological formations, and the character of natural conditions regarding temperature and weather.

The principle of using science and scientific men to improve existing agricultural industries was first developed in Europe, and it is certain that Germany played a leading part during 1870–1890 in this matter. Treub, of the same era, was ideal as director of the Botanical Gardens. He worked on the plan of introducing science for practical application, although it was his original contention that most of the scientific research, for application to special plantation crops, must be affiliated with Buitenzorg. He believed this necessary in order to centralize in one way or another the scientific work; he thought it to be advantageous to move scientific workers about. The idea of centralization was not used, however, by the new "Proef-stations", as the first research centres were called.

The first research centres were organized as private institutions. There were stations for sugar, tobacco, coffee, indigo and for forestry in general. Later, there followed similar centres for tea, rubber, cinchona, palm oil. Then came the Government Agricultural Institute for the study of native crops: rice, copra, cassava, soja, maize and similar produce. The research organizations previous to 1900 employed, in general, phytopathologists; but later agriculturists and biologists, specializing in genetics and physiology, were introduced. In 1930, for example, the total number of workers on the staffs of the Netherlands Indies Governmental and private institutes was 190. These included those working in the fields of agriculture, agricultural industries and technology. All of them were graduates and experts.

At the start, the selection of the research workers was on a broad international base, and most of the European countries sent men of science to work in the Netherlands Indies. This international co-operation was of great benefit to the country. Further, there were the universities in Holland where it was possible to give a limited number of students thorough training. The Netherlands Indies also had the good fortune to have men of science who could read three major foreign languages.

The total number of experts who worked in the Netherlands Indies from 1880 until 1935 was about 850. About 250 of these men had been connected with the Experimental Station for the sugar industry. More than one quarter were foreign residents, while the average time these men were connected with research in the tropics was seven to eight years.

The total number of chemists, agriculturists and biologists engaged in the Netherlands Indies was much greater, however, than the above-mentioned figures. In 1939, there were 250 chemists, of whom 50 were doing research; the others dealt with education, manufacturing processes, consulting agencies and the like. Of the agriculturists, research workers numbered 45 out of 700 in 1939. There were 90 biologists with 25 research workers. The geologists numbered 70, of whom seven were engaged in research. The number of pharmacists was 200, eight of whom were research workers.

Until 1939, the number of Indonesians and Chinese working in science was very small, and the indigenous part of the population provided only five research workers. Their contribution to scientific literature was likewise very small.

---

* Substance of an address given at the September meeting of the Society of Netherlands Scientists in the U.S.A. at Cornell University.

Following the publication of works on science in the tropics, much controversy arose on 'the creation of new wealth'. It was considered for some time, in effect, that the result of scientific study was the property exclusively of those who were paying the bills. Furthermore, they were secret. On the other hand, it was advocated that for scientific progress it was absolutely necessary that publications should be sent to colleagues working in the same fields in other countries, and that free co-operation be a requirement.

Discussion on these points of view began during 1930–32, years of the severest depression. Companies existing at that time thought that a number of foreign competitors had profited specially by the studies in the Netherlands Indies; that the methods developed in the Indies were only copied when free access had been given to all those who were interested in the results of the research work.

Unfortunately, this discussion had as defender a professor. The rights of the vested interests were defended by a lawyer, who evidently put forth the cause of the financing companies to limit and even to forbid foreign co-operation among the scientific workers. In 1933, the final decision for most of the experimental stations was to drop the open-door policy and to try to keep as secret as possible future results from the laboratories. The steps so taken were undoubtedly bad. Only the worst type of 'man of science'—the unreliable and selfish type—saw in this policy of secrecy an opportunity to exploit his own position and his own acumen. In the small, closed communities of manufacturing companies, generally speaking, objective criticism was lacking; and prominence was given those who talked a great deal but said little. The best scientific workers were more or less ignored.

During this unhappy period, the Council for Natural Sciences in the Netherlands Indies made an attempt at a certain amount of co-operation as a counter-measure and, if possible, for the entire Netherlands Kingdom. It did this by an organized exchange of experience between the stations and professors of natural science in Holland, who were acquainted with the problems of the tropics. To this date, however, the matter remains unsettled.

Most of the studies on the Netherlands Indies are published by the stations themselves, usually in the Dutch language, but, where there are large foreign interests, as in the rubber industry, in English as well. The number of technical periodicals distributed throughout the whole world before the War was: engineering, 1; medical, 3; geological, 1; pharmaceutical, 2; chemical and technological, 1; sugar, 2; general agriculture, 3; tea, 1; rubber, 2; cinchona, 1.

In 1914, periodicals in the Netherlands Indies totalled seventeen. About nine tenths of all the studies in the Netherlands Indies were published in these journals, while one tenth was found in other countries. Before the War, the material was contained in Dutch publications; at present it is found in American and British periodicals.

Studying research on the Netherlands Indies reveals excellent co-operation with other countries. The share of work done by foreign men of science, among whom may be mentioned Germans, Swedes, Swiss and Russians, is important. The relations between nationalities and scholars of different universities have been of benefit to all. In the past years, selection of scientific workers has become limited and the trend was preferably national. An additional limiting factor was that well-known professors, or high officials, in the Netherlands were used as liaison officers for the selection of young graduates to be sent to the Dutch Colonies.

There appears to have been an unfortunate narrowing of the field from which men are selected in the Netherlands Indies. After the War, it is to be hoped that all men of science interested in the Netherlands Indies, and living and working in other countries, will stimulate their students to go to the Indies for work and study, because working in the tropics can prove an excellent occupation. The number of research workers in the Netherlands Indies, which has been given above, is very small. The United States has at present 70,000 experts working on natural science. In the Netherlands Indies there is a maximum of 300, partly because some of the findings, especially in connexion with the oil and tin industries, are made in other countries where facilities are better than in the Indies.

The United States at the present time is spending 300 million dollars a year on research. In the Netherlands, three years ago, expenditure amounted to 3 million guilders, which meant that of the exports about one half per cent of export money was used for research. It is generally believed that money used for data on the Netherlands Indies yields profitable returns. In some cases, such funds have had to be increased; but, because of the conditions of prices and quantities of produce to be exported, it is very difficult to stabilize the amount.

It may be expected, however, that the money will be increased eventually. Previous to 1930, more than 80 per cent of the research work was done by private organizations. The trend now is that much more will be done by Government or by private institutes under Government control. It is also to be expected that after the War the Netherlands Indies will ask for more research workers and that they will be asked to come from widely divergent places. The Netherlands Indies are dependent on foreign sources, not only for the scientific workers themselves but also for equipment and literature. Only laboratory buildings and assistants are available in the Indies.

Many countries are even now considering how this research can be directed, including the Indies, where the Government had founded the Council for Natural Sciences for the Netherlands Indies. This may be compared with the Koninklijke Academie voor Wetenschappen, which studied and promoted scientific work in the Netherlands Indies. One of the difficulties for a practical organization is that a number of the directors of experimental stations there must be trained to the right responsibility. Their attitude must still be made more active regarding the proper locale for scientific work, and there still is misunderstanding on the part of a financial board. The director of an experimental station must be convinced that he is the one responsible for the work turned out. He must not be passive about defending the rights of the scientific workers and in finding a proper solution for publication policy as well as in stimulating co-operation. In most experimental stations the scientific locale and general set-up do not rise above the scientific and social outlook of their directors.

Considering the specialized science already established, it may be asked: What of the men themselves to be selected for the future ? A start was made with chemists, and later biologists and agriculturists arrived, followed by the biochemist.

So, the first step to take after the War is to seek men who are suitable. The specialized research worker is not so important, for too much value has been attached to the title rather than to the man, his experience and qualifications. A 'clan' formation in the scientific world may develop with biologists sticking together and agriculturists training themselves in mutual admiration. It must be realized that the physicist, as well as the engineer, the biochemist and the technologist are also useful.

In the Netherlands Indies there has always been considerable discussion about pure and applied research. Naturally, there is not a single experimental station which is not interested in fundamental research work, without regard to specific applications of the facts to be discovered. The danger of an experimental station is not that it is doing too much on pure science, but that a research institute has also to act as a consultant.

In certain conditions, this can result in lack of time for real research. The research worker should not be spoken of as an impractical, unsocial, professorial type, with the "zeal and satisfaction of the crusader", in devoting his whole life to science. Perhaps in the past there have been certain of this extraordinary type of man ; but those who have been in the Netherlands Indies were no strangers in the economic world, and their outlook upon life was just the same as that of common men with common sense. Most of them, however, had great zeal, with an honest idea of scientific truth and with intelligence above the standard.

The Council for Natural Sciences, which has been studying the scientific future for the past two years, will play a leading part in choosing intelligent and zealous men of science, because it is convinced that governmental encouragement and support of research is a necessity ; that the best form for this encouragement is to provide sufficient assistance to existing associations ; and that all research should not be handled by a centralized governmental service. Decentralization of research, with boards interested in the problems to be studied, is the future development to be desired. Further, the funds for research must be increased.

It should also be possible in the future to criticize frankly research in certain industries. The Netherlands cinchona industry, for example, which had been a profitable one, was only using pharmacists and keeping secret everything which they were doing. According to the general feeling of a great number of men of science, however, insufficient research on the details of bark composition, quinine chemistry and manufacture of substitutes was being done ; the industry felt that it was in a safe corner with its secrecy and profits ; but a world with more freedom is the goal, and such secrecy is unpalatable.

An important factor for the future of the Netherlands Indies is that it has decided to create a complete university, with courses in all the natural sciences, to be maintained on the same level as the Dutch universities. Such a university would be an important centre of research in the future. The problems of society *vis-à-vis* science in the Netherlands Indies are not confined to this country. They are general world problems. We must do away with the secrecy impressed upon men of science by their employers. Open discussion is the best for the enlightenment of business executives, and it must be made possible for every man to discuss his work and aims. The post-war scientific world in the Indies must have workers in a free world who feel they belong to a group which has forgotten all limitations set by frontiers, races and laws—because science is one of the expressions of the higher unity of mankind and the world.

ORIGIN OF MALIGNANT TUMOUR CELLS

By Dr. P. C. KOLLER,
Institute of Genetics, University of Edinburgh

IN the light of recent knowledge of chromosome chemistry and gene action and its bearing on the interpretation of the mitotic cycle in the cell, a cytological analysis was carried out on 565 human tumours (carcinoma of the skin, œsophagus, colon, rectum, larynx, lung, cervix, uterus and breast)[1]. It was expected that by analysing the characteristics of chromosome and nucleolus behaviour, abnormalities specific to the internal organization of tumour cells might be detected. The present article contains a brief summary of the data obtained[2].

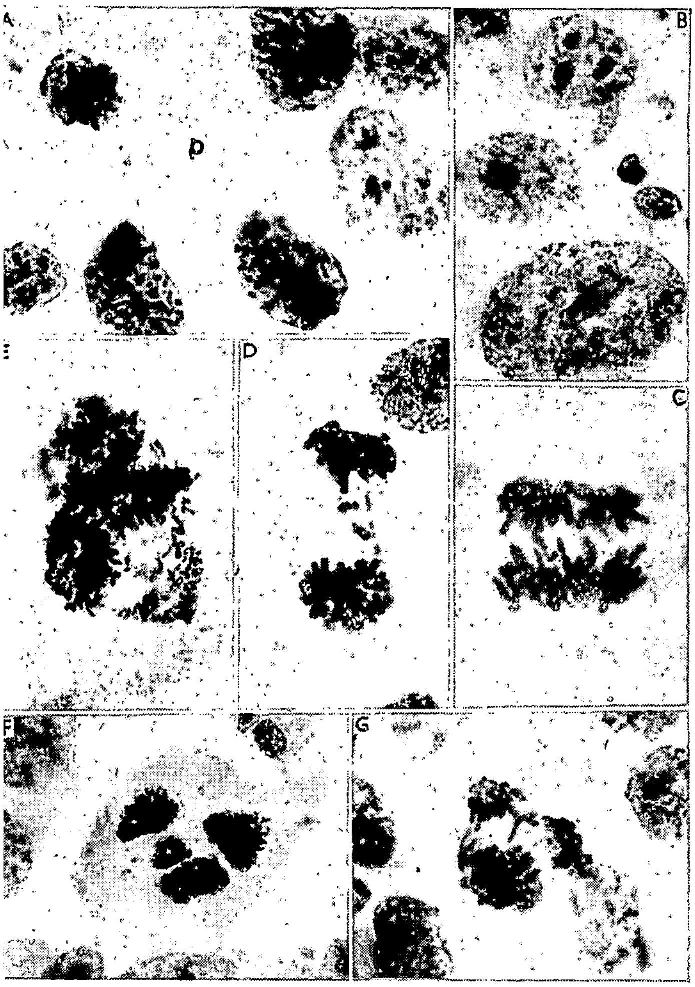
Nucleolus

Pianase[3] had already reported that the nucleolus, a permanent structure in the resting nucleus of cells, is larger in tumours than in normally functioning tissue. His observations have been corroborated since by many investigators[4]. During the last few years cytogenetical research has accumulated experimental proofs that the nucleolus is produced by the so-called 'nucleolar organizers', which are a group of genes located in particular regions of the chromosomes[5]. Nucleoli are formed at the completion of mitosis and their size may increase during the resting stage. They disappear at the beginning of the prophase of the succeeding division. Although there are great differences in the histological structure of tumours of different tissues, the behaviour of the nucleolus is always the same.

It was observed that (*a*) nucleoli in cells of the same tumour differ in their chemical contents ; (*b*) they are of varying size ; and (*c*) nucleoli in cells of different tumours of the same kind may differ in both, that is, in size and chemical content.

Nucleoli giving Feulgen's positive reaction are known to contain desoxyribose nucleic acid ; they usually appear as small, deeply stained granules (*A* in accompanying photograph). Such nucleoli represent heterochromatic regions in the chromosome, which retain the nucleic acid charge during the resting stage. In nucleoli which give a Feulgen's negative reaction, on the other hand, desoxyribose nucleic acid is absent, and, as ultra-violet absorption indicates, there is a large amount of protein of the histone type and the ribose form of nucleic acid. These nucleoli are large (*B*), and they show great variation in size, which is due to the different amount of histone-protein and ribose nucleic acid present.

It is seen that tumours are not homogeneous from a cytological point of view, but are composed of cells with Feulgen's positive and negative nucleoli.



., Tumour cells from cervix, showing the small Feulgen's positive nucleoli (× 800). B, Tumour cells from cervix with large Feulgen's negative nucleoli. One cell is olyploid (× 800). *C*, Anaphase in squamous cell carcinoma of the skin showing ne non-disjunction of a chromosome (× 800). *D*, Telophase in basal-cell carcinoma howing chromosome bridge and lagging of chromosomes (× 800). *E*, Highly polyloid cell in carcinoma of the cervix (× *c*. 670). *F*, Multinucleate giant cell in rcinoma of the cervix (× *c*. 670). *G*, Tri-polar spindle in carcinoma of the cervix (× 800).

The analysis has shown that the proportion of these cells varies (*a*) in different regions of the same tumour at the same time, (*b*) in the same tumour at different times, and (*c*) in tumours of different kinds. The proportion of cells with Feulgen's negative nucleoli increases at the expense of the other cells with the development and growth of the tumour.

Mitosis

Tumour cells exhibit a great variation in respect of the details of division. Tumours were found in which most of the dividing cells undergo the process of mitosis normally; on the other hand, tumours were encountered in which a great proportion of dividing cells have shown many abnormalities. These are expressed in chromosome structure and behaviour and in the lack of co-ordination between spindle mechanism and chromosome movements. A close relationship was found to exist between the frequency of abnormalities and the type of nucleolus. While tumours in which the proportion of cells with Feulgen's negative nucleoli is very small exhibit few abnormalities during mitosis, tumours in which the proportion of these cells is high contain a great number of polyploid and giant cells, and most of the dividing cells exhibit various chromosome and spindle abnormalities. Some of the most common abnormalities observed in tumour cells are summarized as follows:

(1) *Stickiness of chromosomes.* At anaphase and telophase of mitosis in tumour cells the daughter chromosomes remain associated. 'False chromosome bridges' are formed, which prevent the separation of the telophase chromosome groups and may lead, by the failure of division of the cytoplasm, to the formation of binucleate cells. This stickiness of the daughter chromosomes caused the configuration, described by Farmer, Moore and Walker[6] as a "bivalent" because it is very similar to that found during the first meiotic division. On account of this similarity they erroneously believed that carcinogenesis is a process similar to gametogenesis abnormally occurring in somatic tissues.

(2) *Non-disjunction of chromosomes.* Daughter chromosomes often fail to segregate to the opposite poles (*C*, *D*), consequently the two nuclei formed will be unbalanced in respect of the chromosomes content. This abnormality is due either (*a*) to chromosome stickiness or (*b*) to rapid division.

(3) *Displacement of chromosomes.* One or more chromosomes may lie off the equatorial plate during metaphase. Such chromosomes are usually unoriented in relation to the centrosome and spindle.

(4) *Clumping.* The chromosomes during metaphase fail to form a well-defined equatorial plate. Clumping often interferes with chromosome segregation and may result in the degeneration of the chromosome elements.

(5) *Binucleate cells.* These are the result of the failure of cell division to take place after nuclear division.

(6) *Polyploid cells.* In these cells the 48, that is, the diploid chromosome number, is multiplied; the cells are larger than diploid cells. They are due to the failure of spindle formation.

(7) *Multinucleate cells.* These are the result of 'polymitosis' or repeated nuclear division, without cell division (*F*).

(8) *Giant cells* with highly polyploid chromosome number (*E*); these are due to rapid division. Such cells very often degenerate.

(9) *Spindle abnormalities*: (*a*) delay in spindle formation, (*b*) incomplete and (*c*) multipolar spindle (*G*). The result of such spindle abnormalities is incomplete or irregular chromosome segregation, and the formation of unbalanced or polyploid nuclei.

Discussion

The analysis of this aberrant chromosome and spindle behaviour has shown that they are chiefly due (1) to stickiness; and (2) to increased rate of division. It was concluded as a result of the analysis that not only the characteristic abnormalities such as polyploid, multinucleate, and giant cells, multipolar spindles, stickiness, displacement of chromosomes at metaphase in tumour cells, but also the increased rate of division itself can all be attributed to a quantitative change in the nucleic acid synthesis. The argument is here presented, and it is based on data obtained by Astbury[7], Caspersson[8], and Darlington[9].

The chromosomes are known to be long polypeptide chains on which are fixed, at regular intervals, active groups, identified genetically as the genes. The genes, besides being the physical basis of heredity, regulate the division of the nucleus, by attaching to themselves the nucleotides of desoxyribose nucleic acid, which polymerizes in columns (thymonucleic acid) parallel with the polypeptide chains. The polymerization of thymonucleic acid is responsible for (1) the coiling, (2) the reduplication or reproduction of chromosomes, and (3) making them visible. Thymonucleic acid is obtained from desoxyribose, which is provided by the reduction of ribose nucleic acid. The latter is produced in the cytoplasm under the influence of histone.

During the resting stage, the nucleus contains a relatively small amount of thymonucleic acid, because at the end of mitosis most of the nucleic acid charge of the chromosomes is given up. There are chromosome regions (blocks of genes or even whole chromosomes) the function of which is the production of ribose nucleic acid through the formation of histone, which is normally collected and stored during the resting stage in the nucleolus. These chromosome or chromosome regions are designated as heterochromatic, to distinguish them from the euchromatic regions. It is known that the whole or part of the sex chromosomes in animals, the so-called 'inert', and '*B*' chromosomes in various organisms are heterochromatic. For a normal functioning of the cell a specific heterochromatin-euchromatin balance is required. Since the amount of nucleic acid and the rate of its production determine the frequency of division, the excess amount of nucleic acid present in the tumour[10] must be considered as the fundamental cause of increased division-rate and malignancy. Thus the quantitative change in the nucleic acid metabolism, indicated by chromosome behaviour, may be one of the most important differences which distinguish tumour cells from normal cells.

The incorrect balance between heterochromatin and euchromatin, that is, an increase in the nucleic acid supply, may be very slight, and result only in a shortening of the resting stage between two divisions. In this case, which may be considered as the first stage in the development of the tumour, the 'malignant' cell cannot be identified morphologically. The excess nucleic acid over the normal supply, however, besides reducing the resting period, will sooner or later have repercussions in chromosome behaviour. One of the most frequent failures in the mechanism of the division under such conditions is irregular segregation of chromosomes at anaphase, which secondarily leads to a further unbalance and increase in the nucleic acid supply within the cell. This will be manifested now by (1) abnormal chromosome behaviour and (2) by a change in the size and contents of the nucleolus. As a result of the excess amount of nucleic acid produced, the chromosomes become sticky because they are coated with fluid non-polymerized nucleic acid. Several other abnormalities such as those described above will also be exhibited by the chromosomes, and nuclear division will become so rapid that it will not always be followed by cell division. This may be considered as representing the second stage in tumour development.

The cells with a slight extra amount of nucleic acid are gradually replaced by cells with a much higher nucleic acid content. With this change the development and differentiation of the tumour arrives at the third and last stage. Abnormal chromosome behaviour and irregular division become very frequent. The tumour tissues contain a great number of large, giant polynucleate cells, and show widespread cellular degeneration.

These three stages of tumour-cell types have been identified in different tumours, as well as in the same tumour. It is concluded that these stages and intergradations are conditioned by the different increases in the nucleic acid supply within the cell. In most tumours the various cell-types showing differences in the amount of nucleic acid are present side by side. Data were also obtained which suggest that the various proportions of these types in the tumour may be used as a criterion of differentiation and degree of malignancy.

The question is how this excess of nucleic acid supply is brought about within a normal cell ? From genetical and cytological evidence it is known that the heterochromatic regions of chromosomes primarily concerned with nucleic acid synthesis can undergo spontaneous mutation and structural change more easily than other parts[11,12,13].

It is not improbable that the initial change in the nucleic acid metabolism is brought about by a gene mutation which may be assumed to have occurred in the region controlling nucleic acid supply either directly or indirectly. Thus a somatic mutation, as postulated by Lockhart-Mummery[14], would be responsible for the increased nucleic acid supply. The ultimate cause of such mutational change within a normal cell is not yet known. The cytological analysis reveals only the fact that in the tumour cell there is a disturbed nucleic acid metabolism.

Summary

Cytological analysis of tumour cells shows that all chromosome abnormalities and the increased rate of division itself can be explained by assuming that there is a quantitative change in the nucleic acid synthesis due to alteration in the heterochromatic region of the chromosomes[15].

---

[1] The cytological analysis was made possible by the financial support of the British Empire Cancer Campaign, and by the generous help of the Holt Radium Institute, Manchester.

[15] Dr. T. Caspersson, using cytochemical methods, arrived at the same conclusion. His data indicate that "the heterochromatic section of the nucleus must play a very specific role in carcinogenesis" (personal communication).

NEWS and VIEWS

Dr. J. C. Willis, F.R.S.

DR. J. C. WILLIS, the well-known botanist, celebrated his seventy-fifth birthday on February 20. When Dr. Willis was appointed director of the Royal Botanic Gardens, Ceylon, in 1896, he not only developed the gardens to a high state of efficiency but he also began a very fruitful study of the flora of the island, coming for the first time in contact with a most interesting tropical flora. He began with the investigation of the Podostemaceæ, a group of highly modified type of flowering plants which grow on the waterworn rocks of rapidly flowing tropical streams in various parts of the world. When at Cambridge as personal assistant to Sir Francis Darwin, he had accepted with enthusiasm Darwin's doctrine of natural selection, but faced with the fact of numerous species of the same family living under practically similar conditions of life he began to question the Darwinian theory of evolution. Thus the views which he has put forward in his later stimulating books had their origin in his intensive study of the Podostemaceæ.

Dr. Willis's studies of the endemic plants of Ceylon, and later those of New Zealand, confirmed him in his conclusion, formulated in his earlier publications, that the older a species is the greater is its geographical distribution, and vice versa. This view was put forward at some length with numerous examples verified by himself in "Age and Area", published in 1922. As this book met with some criticism, Dr. Willis published in the following year a reply to criticism. Further studies on endemism and geographical distribution have occupied Dr. Willis's time and energy since then and two accounts of his work and his conclusions were given to the Linnean Society in 1936 and 1938 respectively. Advancing age has not diminished his output of important contributions to botanical science, and 1940 saw the publication of "The Course of Evolution by Differentiation or Divergent Mutation rather than by Selection", a book showing the vigour of his mind and summing up with a wealth of mature and critical judgment the arguments in favour of his conclusion. Marooned in Switzerland during the present War, he is still hard at work and last April (1942) he published an article in the *Proceedings of the Royal Society* indicating the kaleidoscopic manner in which the mutations referred to in his "Evolution of Plants" takes place. This publication may be taken as an instalment toward a projected volume on geographical distribution, the publication of which has been retarded by the difficulties caused by the War.

Post-War Commercial Air Transport

THE recent discussion in Parliament upon the necessity for making provision for the development of civil aviation in the immediate post-war period has aroused much interest in many different circles, political, commercial and technical. Mr. F. C. R. Jaques, of North Eastern Airways, Ltd., 31–32 Haymarket, S.W.1, has prepared a memorandum in which he endeavours to apply his experience in commercial air transport to the post-war problem. He suggests that much technical progress in design has been made, necessarily secret at present, that has improved performance, reduced the labour needed for construction, and simplified maintenance. This should be reflected in a general lowering of costs of air transport, the principal bugbear of the earlier air-line operator. If schemes, both for commercial air transport and private flying, are launched with sufficient vision and energy they will help in the problem of re-establishing the skilled personnel of the R.A.F. in civil life.

The memorandum postulates that international freedom of the air is a necessary preliminary for the fullest development of civil flying, and suggests that sufficient balance can be maintained if each country controls its nationals, guaranteeing their bona fides, technical skill, and the airworthiness of their machines. These standards will obviously need to be aligned, at least approximately, by some international agreement. As such did exist before the War there should be no difficulty in resurrecting them. His suggestions include the removal of civil aviation from the Air Ministry, introducing a sense of competition in the air transport world by allowing other selected companies to operate, the development of internal routes possibly by smaller companies as feeders to the big transcontinental lines, and the immediate appointment of a powerful committee to examine such questions.

René-Just Haüy (1743–1822)

ON February 28 occurs the bicentenary of René-Just Haüy, recognized everywhere as the founder of the science of crystallography. Born in the small town of St. Just, in the Department of Oise, he was the son of a weaver, but in spite of his poor circumstances gained admission to the College of Navarre, in Paris, and at the age of twenty began to teach there. Led to the study of minerals through an accident with a crystal of calcareous spar, he discovered the law of crystallization, and became widely known thereby. In 1783, at the age of forty, he was elected to the Academy of Sciences, and in the following year he published his "Essay in the Structure of Crystals", the first of his various books. He was deprived of his posts at the Revolution, and for a short time imprisoned; but after the fall of Robespierre, he took his place among his scientific peers, being given a chair in the short-lived Normal School, and a seat in the Institute. He was also made keeper of the mineralogical collections at the School of Mines and secretary to the Commission of Weights and Measures. In 1802 he became professor of mineralogy in the Natural History Museum, where his lectures attracted large audiences. His numerous memoirs are to be found in the periodicals of the time. He continued to lecture to an advanced age, and died in Paris on June 3, 1822. His collections and his statue are in the galleries at the Museum, and on November 8, 1903, a monument to him and his brother, Valentin Haüy (1745–1822), a pioneer in work for the blind, was unveiled at St. Just, when a discourse was pronounced by Lacroix. The *American Mineralogist* (No. 6, 3, 1919) contains a series of articles on aspects of Haüy's life and works and includes a number of portraits.

British Mammals in War-time

THE increase of many species of British birds due to war-time changes in the countryside has already been noted in NATURE. Evidence is now accumulating to show that many British mammals are likewise increasing, and one of the most welcome is the pine-marten, which had reached a dangerously low population in many districts. Reports were recently made of its presence in North Wales at Bettws-y-Coed (*Field*, Jan. 1943), and in Scotland in the Forestry Commission and deer forest areas of the Highlands and in a cairn in the Grampians (H. M. Batten, *Scotsman*, Jan. 30, 1943). In Lakeland it has recently been reported from Ennerdale. The polecat is also increasing in the wilder parts of Great Britain. Foxes have increased at an alarming rate in most parts, even where there were no organized hunts as in Lancashire, while in Lakeland, where the Eskdale Hunt killed a record total of sixty foxes in January, there is considerable controversy over organized fox hunts.

The Scottish mountain hare, which inhabits only a few parts of the Pennines at Penistone above Sheffield, has wandered from the Cheviots, where it is plentiful, to inhabit some of the moors on the extreme northern fringe of Cumberland above Gilsland and Bewcastle. The increase of stoats, weasels and badgers is of considerable agricultural value, because rabbits form such a large part of the food of stoats and badgers, and weasels feed mainly on field mice. The increase of foxes is responsible as much as is trapping for the reduction of rabbits, which form the chief food of foxes, but their depredations upon poultry have necessitated a campaign against them.

A Laboratory in Physical Geography

A development in geographical research and teaching is the subject of an article in the *Geographical Journal* of November–December by Prof. F. Debenham, in which he describes the laboratory for physical geography which he has planned and equipped at Cambridge, even though the exigencies of the times have necessitated its temporary dismantlement. The object of the laboratory is to study field processes, usually in miniature, under conditions of close observation and control with the view of ascertaining their mechanism, stages and effect. An amazing array of apparatus has been crowded into one room barely 50 ft. long by 19 ft. broad. In the wave trough, waves are generated by various methods and ingenious devices allow the measurement of period, height, length, etc. Here also beach building with sand and shingle can be studied. The wave tank, on a smaller scale, provides, among other aims, for the study of land forms produced by long-shore drift. An even more ambitious piece of apparatus is the tidal tank in which the difficulties of producing tidal currents seem to have been overcome, and good results are expected. The stream flume or delta tank seems to work well in the study of alluvial deposition, and the stream curve apparatus is to be used for the investigation of water movement in the bed of a stream. Other problems, too, are to be studied, and the whole laboratory is a promising step in the introduction of quantitative methods in the problems of physical geography.

Public Library of South Australia

The first report of the Public Library of South Australia, which was formed under the Libraries and Institutes Act, 1939, creating a Libraries Department under a Libraries Board of South Australia, with a Principal Librarian as administrative head, covers the half-year ending June 1940, and stresses the need for the permanent allocation of sufficient land for the natural growth of such an essential service. The various properties of the Public Library, the Museum and the Art Gallery have now been re-allocated, but despite adaptations the accommodation for library work, particularly for staff and for the country lending service, is entirely inadequate. War conditions have not affected adversely the use made of the Library, as is shown by an increase in readers of more than 7,000 during the year, and the Library staff has been taxed to its utmost to provide information regarding all sorts of conditions arising from the War. Financial provision for books is still inadequate and the Board has recommended the establishment of a research department for handling requests for scientific, technical and economic information. For this a more extensive range of periodicals is urgently required. The country lending service has also been called upon for books beyond the limit of its capacity, and its work has grown so rapidly that early extension of accommodation is necessary to provide adequate working space. The Archives Department has reached the limit of its shelving accommodation and offers of many important series of documents, arising from the present extensive pulping of old records, cannot be accepted because of lack of accommodation.

Joints in Submarine Cables

R. Miller and C. T. Rose contribute an article on this subject in the Engineering Supplement of *Siemens Magazine* (Oct.–Nov., 1942). In submarine cables particular care has always to be exercised in dealing with the joints, and every endeavour is made to limit their number by manufacturing individual cable lengths as long as possible, consistent with the methods of transport, storage accommodation, etc., available, and the scheme of laying to be adopted. With submarine cable-laying under normal conditions, it is unlikely that more than one sea joint will be necessary, the cable being laid in two parts, one section from each shore termination. This necessitates cutting the cable at a convenient position, buoying the end, and picking up again after the other section has been laid. The joint is then made on the ship and on completion is cast overboard, after due precautions have been taken. The article refers to both communication cables and power cables, the latter for voltages, for example, up to 33 kV. In the section on communication cables the authors discuss gutta-percha joints, splicing the sheathing wires, rubber joints, rubber to gutta-percha joints, and paper joints. The section on power cables is confined to those of the impregnated paper-insulated and lead-covered types and describes the making of subaqueous joints, super-tension joints and the handling of the shore ends of the cable. The article is illustrated and several photographs are included showing different stages in the operations of laying submarine cables.

Conference of X-Ray Analysis

The analysis of substances and the examination of their behaviour by X-ray diffraction methods has become of considerable importance in the war effort. The Institute of Physics is therefore arranging a second conference on the subject to take place in Cambridge during April 9–10. The provisional programme includes a lecture on "Future Developments in X-Ray Crystallography" by Prof. J. D. Bernal, and discussions on "Quantitative Treatment of

Powder Photographs", "The Fine Structure of X-Ray Diffraction" and "Line Broadening". A report is to be presented to the Conference on the progress made in the preparation of an index to X-ray diffraction photographs, for which the Institute has undertaken to be jointly responsible with the American Society for Testing Materials and the American Society for X-Ray and Electron Diffraction. Further particulars of the Conference and of the Index can be obtained from the Secretary of the Institute of Physics (temporary address: at the University, Reading).

The Night Sky in March

New moon occurs on March 6d. 10h. 34m. U.T., and full moon on March 21d. 22h. 08m. Conjunctions with the moon are as follows: March 3d. 03h., Mars 3° S.; March 4d. 19h., Mercury 2° S.; March 8d. 08h., Venus 3° N.; March 12d. 11h., Saturn 4° N.; March 15d. 18h., Jupiter 4° N.; March 31d. 22h., Mars 2° S. Occultations of stars brighter than magnitude 6 are as follows: March 12d. 16h. 40·2m., α Tauri (*D*); March 12d. 17h. 51·8s., α Tauri (*R*); March 17d. 22h. 43s., o^1 Cancri (*D*); March 17d. 23h. 03m., o^2 Cancri (*D*). The times are given for Greenwich, and *D* and *R* refer to disappearance and reappearance respectively. Mercury is a morning star at the beginning of the month. Venus is a conspicuous evening star and sets about 2h. 40m. after the sun in the middle of the month. Jupiter souths at 19h. 36m. in the middle of the month and is visible for the greater part of the night. Saturn is becoming an evening star and sets about midnight towards the end of the month. Vernal equinox commences on March 21d. 12h.

Comet Whipple will probably still be visible through a small telescope. An ephemeris is given below.

Announcements

The War Office announces that in deference to a request from the Lord President of the Council, it has been agreed that Sir Charles Darwin, scientific adviser to the Army Council, shall return to his duties as director of the National Physical Laboratory on March 1. He will be succeeded as scientific adviser by Prof. C. D. Ellis, Wheatstone professor of physics, King's College, London, who has been serving as deputy scientific adviser.

Prof. F. C. Lea, emeritus professor of engineering in the University of Sheffield, has been elected president of the Institution of Mechanical Engineers.

Sound films of honorary members and Faraday medallists of the Institution of Electrical Engineers are being shown before the Institution as follows: March 4: Sir J. J. Thomson and Lord Rutherford; April 1: Sir Ambrose Fleming and Dr. A. E. Kennelly; April 29: Lord Hirst and Dr. F. B. Jewett. Each meeting will be at 5 p.m.

The Herbert Jackson Prize for 1942 of the London Midland and Scottish Railway has been awarded to Mr. J. Dearden, of the Metallurgical Section of the Railway's Research Department, for papers entitled "The Inspection of Welded Steel Joints in Relation to their Static Mechanical Strength" and "The Influence of Welding Defects on the Resistance to Fatigue of Welded Steel Joints".

The third Pan-American Congress of Endocrinology will be held at Buenos Aires during July 1–6, when discussions will be held on the endocrine factors in diabetes, gonadotropism and the suprarenal cortex. Further information can be obtained from the Office of the Congress, Córdoba 2122, Buenos Aires.

The British Laboratory Ware Association, Ltd., has recently formed a technical committee, the objects of which are as follows: (1) To promote closer co-operation between bodies responsible for the design of standard laboratory instruments and apparatus and the manufacture of same. (2) To assist in rationalization of the design of apparatus and to eliminate overlapping, with the aim of securing economical production. (3) Collaboration to these ends with standardizing authorities, research associations, etc., in the drafting of specifications. It is hoped that research and other associations will avail themselves of the facilities offered in order that improved service and quality may result to users of the apparatus. All communications should be addressed to the secretary of the Technical Committee, British Laboratory Ware Association, Ltd., 73 Basinghall Street, London, E.C.2.

We have received a copy of the catalogue entitled "Medical Miscellany Lot 'G' ", published by Schuman's, 20 East 70th Street, New York, of which the special feature is an extensive section on psychiatry and neurology. Among these mention may be made of the following works: Esquirol's "Mental Diseases in relation to Medicine, Hygiene and Medical Jurisprudence" (first French edition, 1838), Griesinger's "Mental Pathology and Therapeutics" (Sydenham Society, 1867), Charcot's "Diseases of the Nervous System" (New Sydenham Society, 1877–89), Ramon y Cajal's "Structure of the Optic Chiasma" (first German edition, 1899), and Freud's "Three Contributions to the Sexual Theory" (first English edition, 1916). Other interesting works contained in the catalogue are Fracastoro's "Poem on Syphilis" (Latin text and French translation, 1753), the "Genuine Works of Hippocrates" (Sydenham Society, 1849), Hirsch's "Handbook of Geographical and Historical Pathology" (New Sydenham Society, 1883–86), and Hirsch's "Biographisches Lexikon" (second edition, 1929–35).

Erratum. In Nature of February 20, p. 219, paragraphs on "Science and Government" and "Parliamentary and Scientific Committee", reference was made to the "scientific advisers to the Ministry of Supply"; it should have read "scientific advisers to the Minister of Production", as is indicated on the chart on p. 206.

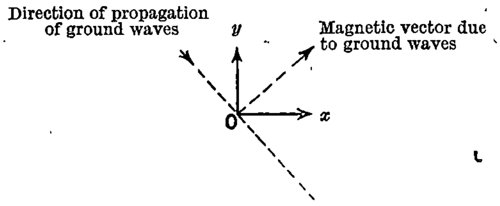
A Simple Method of Demonstrating the Circular Polarization of Ionospherically Reflected Radio Waves

Since the ionosphere is a doubly refracting medium, due to the influence of the earth's magnetic field, a plane-polarized radio wave incident normally on it is split into two elliptically polarized components of opposite rotational sense. For a certain range of frequencies, in the neighbourhood of the gyro-frequency, only one of these two components is reflected in strength, the other being strongly absorbed. In northern temperate latitudes this reflected component is of left-handed, approximately circular, polarization. In corresponding latitudes in the southern hemisphere the sense of the polarization is reversed.

To demonstrate the circular polarization of ionospherically reflected waves in such cases it is necessary to show that the two components of the magnetic vector along the two axes Ox and Oy in the ground plan are equal and are 90° out of phase. (See Fig. 1, where the direction of propagation of the downcoming waves is supposed to be normally into the paper.) If two equal loop aerials are placed with their axes along these directions, the electromotive forces in these aerials will have the same phase difference as the magnetic vector components; but to exhibit the value of this quantity on a cathode-ray oscillograph requires both pulse transmissions and elaborate receiving equipment in the form of two high-frequency amplifiers of exactly similar phase and amplitude characteristics.



Direction of propagation of ground waves
y
Magnetic vector due to ground waves
O
x

Fig. 1.

It is, however, possible to demonstrate this phase difference in a much simpler manner. Let us suppose that the incoming signal is caused to beat with a locally produced oscillation, the frequency of which is very slightly less than that of the downcoming waves. Low-frequency beats can then be obtained from the signals in the two aerials, and it may be shown that the phase difference of the two beat envelopes is then exactly the same as that of the two high-frequency components under examination in the two aerials.

To produce the required low-frequency beats it is not necessary to provide a separate heterodyne, since the oscillations produced by the ground waves answer the same purpose. During the early morning when the height of ionospheric reflection is being slowly reduced, under the increasing solar influence, the frequency of the reflected waves is slightly higher than that of the ground waves due to Doppler effect. The variations which then take place in the outputs from the two aerials are due to the beats between ground and ionospherically reflected waves, and the phase difference we seek to demonstrate is equal to that between the signal variations in the two systems. If we set the two loops at 45° to the directions of propagation of the ground waves, we ensure that the ground waves have equal influence on both systems, and, if each aerial is provided with a rectifier and recording galvanometer, the relative magnitudes of the fading depths and the phase difference between the fading cycles can be simply demonstrated.

With waves of frequency of 2–3 Mc./s., the early morning fading is usually quite regular and the two records are similar to those shown in Fig. 2. It will be seen that the vector along Ox leads that along Oy by 90° and this, together with the fact that the fading is of equal depth in the two cases, shows that the downcoming wave is of left-handed circular polarization.

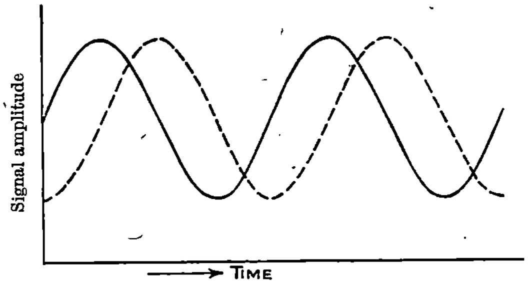


Fig. 2. THE FULL LINE REPRESENTS THE SIGNAL VARIATIONS IN THE LOOP WITH AXIS Ox; THE DOTTED LINE THOSE IN THE LOOP WITH AXIS Oy.

In the case of observations made in the evening (for example, on medium wave broadcasting stations) the ionospheric height of reflection is increasing, and the frequency of the down-coming waves is therefore slightly less than that of the ground wave. The phase difference between the beats as produced with a common heterodyne (that is, the ground wave) is then shown by the examination of the fading curves read in the *negative* direction along the time axis, since the beat notes are then reversed in phase relative to the original signals.

Absolute X-ray Wave-lengths

An important discrepancy is beginning to make itself felt in X-ray diffraction measurements. At present, lattice spacings of crystals are based on the Siegbahn X-unit[1], which is defined as 1/2814·00 of the 200 spacing of rocksalt; this definition made the X-unit as near as possible to 10^{-3} A., in the light of the then-known value for Avogadro's number, N_0. Such a standard was necessary because relative measurements of wave-lengths could be made much more accurately than absolute ones.

So long as the same value of N_0 was used both to specify the scale of X-ray wave-lengths and to work out the contents of a unit cell, no important errors could arise. Now, however, the accepted value of

Avogadro's number[2] has been decreased by about 0·6 per cent from the value on which the X-unit was based. The new value is derived from the measurement of the density and unit cell of calcite[3], the wave-length of the X-rays used being determined on an absolute scale by diffraction from a ruled grating. The error is equivalent to the statement that the X-unit differs from 10^{-3} A. by 0·2 per cent. Therefore, if the new value of N_0 be accepted, one cannot use the Siegbahn scale of wave-lengths.

The formula for the number of molecules, n, in a unit cell is

$$n = \frac{N_0 \rho V}{M},$$

where ρ is the density, V is the volume of the cell, and M is the molecular weight. There are two ways of evaluating correctly n, M or ρ from this equation.

(1) The most recent value of N_0, 6·0228 (±0·0011) × 10^{23} mole^{-1}, may be used, and V expressed in A.[3], that is, in absolute units. In order to derive the lattice constants the X-ray wave-lengths used must be corrected from the Siegbahn scale; some examples of the necessary changes are shown in the accompanying table.

		X-units	Ångström units
	$K\alpha_1$	1537·395	1·540522
Cu	$K\alpha_2$	1541·232	1·544367
	$K\alpha$ (weighted mean)	1538·7	1·5418
	$K\beta_1$	1389·35	1·39218
	$K\alpha_1$	707·831	0·709271
Mo	$K\alpha_2$	712·105	0·713553
	$K\alpha$ (weighted mean)	709·26	0·71070
	$K\beta_1$	630·978	0·632261

(2) If one wishes to retain the Siegbahn scale, one must use an arbitrary value of N_0, namely, 6·060 × 10^{23} mole^{-1}. In this case the lattice constants are in 1,000 X-units, although it is an invariable practice to call them Ångström units.

An error of the order of 0·6 per cent will occur if the new value of N_0 is used with the Siegbahn wave-lengths; this may be quite considerable if substances of high molecular weight are being studied.

The question arises as to which is the better of the two procedures. There is no doubt that the more logical is the former, in which case all wave-lengths need to be converted to Ångström units by multiplying the X-values by $1·00203_4 \times 10^{-3}$, the conversion factor given by Bearden[4]. There are two main obections to this. First, there may be some confusion during the change. Warren[5] has suggested that this confusion would be lessened by using the symbol AA' to express 'absolute Ångström units'. Secondly, the conversion factor is still not known so accurately as are the relative wave-lengths, and so another adjustment may have to be made later. The relative wave-lengths are known probably to 0·001 per cent; and though Bearden is of the opinion that the conversion factor is also known to 0·001 per cent, Birge puts the error much higher, namely, 0·006 per cent. It might thus be thought preferable to wait until the conversion factor is known more accurately. It is possible, however, that no great improvement in accuracy can be expected with present techniques, n which case there would be no point in delay on his account.

Our own opinion, and that of the members of this laboratory with whom we have discussed the matter, s that the new wave-lengths should be adopted; nd it is hoped to get a more general opinion at the second X-Ray Conference of the Institute of Physics o be held in Cambridge in April. We should, however, be glad to know the opinions of others who may be interested in the question, and whose results may be affected by it.

Penillic Acid, an Optically Active Acid from Penicillin

WE have observed that when highly active penicillin preparations are kept in aqueous solution at pH 2 there occurs a rise in the optical rotation which reaches a maximum and there remains constant. After this treatment only part of the material formerly readily extractable by ether can be removed by this solvent and there is left in the colourless aqueous phase a substance which is strongly dextro-rotatory and has a pale bluish fluorescence in ultra-violet light. This substance, which we have named *penillic acid*, can be extracted from the aqueous solution by butyl alcohol, from which it can be separated in crystalline condition. Penillic acid has been obtained in this way from barium penicillin preparation varying in activity from 300 units to 1,200 units per mgm., and as the yield is directly proportional to the biological activity of the penicillin used it seems not unlikely that penillic acid is derived from penicillin itself and not from its concomitants. The best yield so far obtained amounts to 20 per cent of the barium penicillin.

Penillic acid crystallizes from water in brilliant rhombs or in hexagonal plates which decompose at about 175° with evolution of gas but without charring. In aqueous solution ($c = 0·2$) it has the high specific rotation of + 600° for the mercury green line. The solution of the recrystallized material shows the pale bluish fluorescence referred to above. It is acid to litmus and has some of the properties of an amino-acid. It gives a deep bluish-purple colour with ninhydrin and is precipitated by mercuric chloride and phosphotungstic acid. It forms a sparingly soluble silver salt. It readily decolourizes bromine water without formation of a precipitate. It does not give the blue colour with ferric chloride characteristic of penicillamine[1].

The penicillin used in these experiments was purified by the silica gel – barium carbonate column recently described by Catch, Cook and Heilbron[2] from penicillin kindly supplied by Dr. C. G. Pope, of the Wellcome Physiological Research Laboratories, to whom we make grateful acknowledgment.

The work described above was carried out under the auspices of the Therapeutic Research Corporation of Great Britain, Ltd.

Linkage of Physico-Chemical Processes in Biological Systems

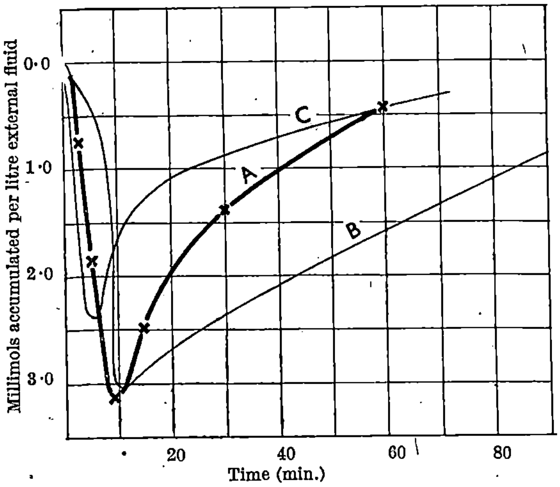
IN a recent communication in NATURE[1], it was pointed out that the shift of equilibrium between extracellular and intracellular potassium during fermentation of sugar either by yeast or bacteria[2,3], was a striking example of the general application of certain principles underlying the accumulation of potassium in cells[4,5,6,7]. If our views as to the nature of such in and out movement during fermentation are correct, it should occur with other cations besides the potassium ion, provided they can diffuse across the cell membrane, or in other words, it should not be *specific* for potassium.

Such another cation is ammonium, and we have recently found that a shift of the ammonium ion occurs in 'ammonia' yeast just as it occurs in 'potassium' yeast.

The 'ammonia' yeast was formed by replacing all the potassium in ordinary baker's yeast in the manner previously described[8], the concentration of the external ammonium being $N/5$ and the process hastened by maintaining at 37° C. The concentration of potassium in such 'ammonia' yeast was much less than 1 mgm. K/100 gm. Yeast so treated was then washed a few times with 0·3 per cent sodium chloride, and left for some hours suspended in this solution, when the external ammonium ion concentration was about 20 mgm./100 ml. To a measured volume of this yeast suspension (1 in 3) was added a small amount of a concentrated solution of glucose and sodium acid phosphate to produce 1·4 per cent glucose in the mixture and $M/140$ phosphate, and to an equal volume of the yeast suspension the same addition was made but without the glucose. The ammonia content of the external solution was examined after varying times, and the values for the mixture containing glucose subtracted from the control figures, giving in one typical example curve *A* in the accompanying graph, which is compared with the curves of K accumulation, *B* and *C*, of Pulver and Verzar[2] with yeast (second experiment in their paper), and of Leibowitz and Kupermintz[3] for bacteria (*E. coli*). Similar curves for 'ammonia' yeast were also obtained in repeat experiments on the same yeast where glucose in saline was added to the mixture from which glucose had disappeared by fermentation, and saline to the control mixture.

This movement of potassium and ammonium ions is in itself to be differentiated from possible specific effects of the ions on yeast activity or that of yeast extracts. For this there is an extensive literature. A short review is given, for example, by Stavely *et al.* in their first paper on zymin[8]. From a recent communication in NATURE[9], Farmer and Jones appear to have obtained some new evidence in this field.

The explanation previously given of the potassium shift during fermentation, which now extends to a similar ammonium shift, would appear quite satisfactory, and relates to those principles which are fundamental to the accumulation of potassium in cells[4-7]. The ion movement would appear to be controlled by the effective product of the free phosphate and potassium (or ammonium) ion concentrations (free phosphate being present mainly as the univalent ion at the pH obtaining within and without the cells). When glucose diffuses into the cells, there is a very rapid formation of glycogen, according to Willstätter and Rohdewald[10]. In the first two minutes, 90–100 per cent of glucose which has diffused in is present as glycogen. This stage is rapidly followed by a marked increase of phosphate esters formed from the glycogen. In the present explanation it is then supposed that the product of the potassium (or ammonium) and phosphate ion concentrations falls steeply and phosphate ions enter with K (or NH_4), the diffusible cations being held within by the electrostatic attraction of the newly formed non-diffusible ions. When these are broken down again the process is reversed, and K (or NH_4) leaves the cells.



This explanation does not imply that there is a simple equality of concentration products within and without the cell, as would be considered for a Donnan equilibrium of the simplified kind for very dilute solutions, for, apart from the effect of the total ionic concentration, the yeast cell membrane is practically non-distensile and the internal pressures are likely to be very much different from those without, with corresponding alteration of the ion activities; but it does imply that an equilibrium will occur with a definite ratio of the products of the ion concentrations (probably not far from unity) and that a change in this ratio will influence the movements of the ions in the direction of its restoration.

Further work on this question is in progress, being assisted by a grant to one of us from the Irish Medical Research Council.

Mechanism of Lysis of Red Blood Cells

STUDY of the etiology of blackwater fever has le us to examine the wider problem of the mechanism of red cell destruction in the body. A summary o the preliminary work and the conclusions reached i given below.

We have observed that certain tissues (lung, liver kidney, spleen, bone marrow and muscle) will lys saline suspensions of washed red blood cells. This lysis is observed consistently only if the tissues are themselves first thoroughly washed or rinsed in saline. On the other hand, tissue slices have little or no lytic effect on suspensions of unwashed red cells.

Inhibition of this lysis is produced by: (*a*) The addition of the animal's serum to the mixture of tissue plus red cell suspension. This inhibitory effect of serum is not confined to the animal's own species, but can be produced by the exhibition of sera of other species. The inhibitory effect of heterologous sera is, however, observable only in a definite zone of dilution. This is particularly noticeable in the case of human serum, which in low dilutions has been found to lyse guinea pig red cells even in the absence of washed tissue. (*b*) The addition of sodium cyanide in a dilution of as little as 1 in 20,000,000 and of mercuric chloride in a dilution of 1 in 32,000. (*c*) Heating the tissue to a temperature of 80° C. or above for a period long enough to affect all the tissue used in the experiment.

Species used in these experiments have been man, monkeys (Cercopithecus, Erythrocebus, Colobus) and guinea pig. So far as our experiments have gone, the lytic agent appears to be species specific, while the serum inhibitor is not.

Consistent results have been obtained with guinea pig tissue, using washed guinea pig lung as the lytic agent and a 5 per cent physiological saline suspension of guinea pig red cells, washed three times in physiological saline, with or without the addition of 5 per cent glucose.

In the uninhibited red cell suspension – washed tissue system, lysis is completed in 18–24 hours.

The strictest aseptic technique must be employed throughout these experiments. It is essential that all glassware should be scrupulously clean by chemical standards.

It is difficult to conceive that the lytic agent demonstrated by the above experiments can be other than an enzyme, although as yet we have been unable to perform the crucial respiratory experiments. If our contention is correct, there exists in the animal body an enzyme capable of destroying red cells. The activities of this agent are held in check by an inhibiting substance which is present in both the tissues and the blood serum. The degree of lysis occurring at any time in the animal body may thus depend upon the balance of inhibitor over lytic enzyme activity. Abnormal degrees of lysis such as those met in blackwater fever and other lytic anæmias may therefore be due either to interference with the activity of the inhibitor or to its actual destruction.

A New Land Nemertean

IN January 1938, Yngvar Hagen, zoologist of the Norwegian Scientific Expedition to Tristan da Cunha (1937–38), discovered a new nemertean species on Nightingale Island. The animal was found attached to the underside of boulder stones situated on a beach, though far above the high-water mark. The fauna of the area was quite a terrestrial one, as land snails, mites and spiders were also found there. The worm was later handed to me for a closer examination, and this investigation has now been finished. Publication of the paper must wait until after the War, but I should like nevertheless to place this interesting find on scientific record now.

The animal turned out to be a new species of terrestrial nemertean, belonging to the genus *Geonemertes* Semp., which I have called *Geonemertes nightingaleensis*, n. sp. The length varied from 3 to 29 mm. In colour it is olive-grey, with two broader black-brown dorsal stripes. Four eyes were found. The animal is characteristic in its lack of an accessory lateral nerve and a frontal organ, the cephalic gland, however, being well developed. The animal seems to be more closely related to *G. agricola* and *G. chalicophora* than to the other members of the genus.

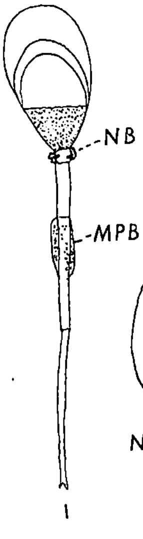
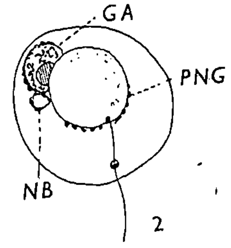
Middle-Piece Beads in the Cavia Spermatozoon

IT is well known[1] that the silver nitrate methods of Da Fano, Cajal and Aoyama for the Golgi apparatus impregnate densely a bead just around the neck of the guinea pig sperm (Fig. 1, *NB*). It has been assumed that this bead is identical with the middle-piece bead depicted by Retzius[2] in so many kinds of mammalian spermatozoa.

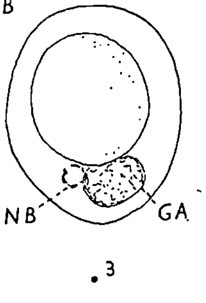
We have recently been studying the spermatogenesis of the dog, and in trying to clear up some difficult points, we have reviewed the spermatogenesis of the cavy. We have been able to show that there are two beads on the spermatozoa from the epididymis, as shown in Fig. 1. The upper (*NB*) is extremely argentophile, and we have easily followed it back to the early spermatocyte in both the dog and the cavy (Fig. 3), as a vesicle almost invariably lying against the sphere (Golgi apparatus). The lower (*MPB*) is certainly the structure depicted by Retzius[2] (Taf. XLV, Fig. 3, etc.) and so far we have



1



2



3

not found it on ripe spermatozoa within the testicular tubules. In such silver preparations as we have examined, it appears after the spermatozoa have entered the epididymis, and while it is generally found in the middle region of the middle-piece its position may vary. The position of the upper bead (*NB*) never varies, though its size may slightly. The material of the lower bead (*MPB*) assumes a brown colour on impregnation, like the secretion of the epididymis. More than this we cannot say at present.

On the point of the origin of the upper bead (*NB*) by budding from the Golgi apparatus remnant, as was previously believed by observers who have studied this matter, we cannot now support such an account. It is quite true that the bead (*NB*) is closely associated with the Golgi apparatus, before, during, and for a time after, the secretion of the acrosome (Fig. 2), so as to give the appearance of budding, but this view must be abandoned, since what is undoubtedly the same bead can be seen in the newly-formed spermatocyte and spermatid both in dog and cavy. It is interesting to note that the upper bead (*NB*) in the dog is very clearly formed of a vacuole and several separate argentophil elements. A similar structure was described in the human by one of us[3] some years ago, only in this case not so closely associated with the Golgi apparatus. Further work in the human is being undertaken in an endeavour to clear up this point.

The Countryside As It Was

In his notice of my book, "Field Fellowship", the reviewer makes certain animadversions on my "scientific accuracy". The issue over whole wheat flour is not one between white and brown bread but bread deprived of the wheat germ by the modern roller mills and bread which contains this nutritive essential. The "manchet" bread of the Middle Ages *was* white bread, but not faked bread. When it is considered that 26,000 of the stone-grinding country mills (which retain the wheat germ) have become derelict in Great Britain owing to the enormous powers exercised by the roller mill interest, it is scarcely surprising that the public have accepted the white bread of the latter. There has been virtually no alternative except by considerable trouble to find a stone-grinding mill and at the necessarily higher price. Eighteenth century white bread was of course never wheat-germless; the process of extraction had not yet been invented.

The reviewer says that the "village garage mechanic" is an adequate substitute for the demise of the rural craftsman. The whole point of rural industry as practised in Great Britain for at least three thousand years was its intimate association with, and dependence upon, agriculture. The garage mechanic has no such organic relationship with the land.

The mechanization of agriculture is and must be as a substitute for human labour. This is quintessential in war-time, but disastrous in peace, because it must necessarily increase unemployment at a time when the problem of employment is the most harassing that modern governments have to face. Also, the small farm can never be mechanized to the same extent as the large, so that the whole tendency of excess mechanization is the formation of "Latifundia", which experience has shown to be extremely deleterious to fertility.

The reason for "the intellectual stagnation" of village life in the past was the effect of the enclosures and the industrial revolution in breaking down the whole structure and pattern of country life. All the best blood was either transported to the Colonies or drawn off to the towns. The restoration, not the urbanization, of country life is surely the remedy.

H. J. Massingham.

Reddings,
Long Crendon, Bucks.

With regard to Mr. Massingham's first comment. The point made in the review was that the public had adopted the whiteness of the bread as their criterion of its desirability long before the roller mill was introduced, so that the roller millers cannot be accused of originating this criterion. They have never had to advertise "Eat Whiter Bread"; it is Mr. Massingham and the nutritional experts who have tried to persuade the public to "Eat off-white Bread", that is, stone ground or "manchet" bread, which the majority still prefer not to do.

The review did not pass judgment on whether any one village craftsman is an adequate substitute for any other. The point made was that new crafts are in fact springing up in the village. The good garage mechanic has often the same relation with the land as the village blacksmith. Neither are of the land, but it was the smith who enabled much of England to be brought under cultivation two thousand years ago. Was he an adequate substitute for the demise of the flint knappers?

Mr. Massingham makes three statements about mechanization. First, that it decreases employment. This statement depends entirely on economic policy, for before the War many farmers actually increased the number of men employed when they turned to mechanization, as they could then intensify their agriculture. Secondly, that the small farm can never be mechanized to the same extent as the large. Categorical statements about future developments can rarely be statements of fact, so that Mr. Massingham must allow me to part company with him here, as pointed out in the review itself. Finally, he states that mechanization tends to the formation of "Latifundia", which are extremely deleterious to fertility. It is difficult to argue a point like this, owing to the vagueness of the word "Latifundia" applied to present-day conditions. There is no evidence that mechanization has yet increased the number of large farms, and, for reasons largely irrelevant in Great Britain, the trend of agricultural engineering development is towards small machines that can work irregularly shaped fields. The real flaw in Mr. Massingham's arguments is that he thinks of mechanization as applied to grain ranching only, which was the first but will not be the last set of agricultural operations to be completely mechanized. The marriage of the tractor to the dairy cow is rapidly taking place wherever agriculture is founded on Western European methods.

E. W. Russell.

Rothamsted Experimental Station.

NATIONAL RESEARCH COUNCIL OF CANADA

SCIENTIFIC research in Canada during the past three years has been directed almost wholly to the solution of new and urgent problems arising out of the War. The National Research Council is serving as a central co-ordinating body directing research within its own laboratories and in the universities and industry. The Council has been appointed the official research station of the Navy, Army and Air Force in Canada.

For the Navy

Scientific problems arising in connexion with the work of the Navy are studied jointly by officers from Naval Headquarters and civilian personnel on the Council's staff. The National Research Council maintains civilian scientific groups at several points on both the Atlantic and Pacific coasts who work in the closest co-operation with the Naval stations. A group is also located in Ottawa and contact is maintained with similar research stations in the United States and Great Britain.

Many of the problems presented relate to the supply of materials and the preparation of specifications. Highly technical problems have arisen from anti-submarine warfare and minesweeping operations. Several sections of the Division of Physics and Electrical Engineering are concerned almost exclusively with research and development programmes for the Royal Canadian Navy. In the Electrical Engineering Section a shock and vibration machine based on standard British Admiralty design has been installed. The specifications for building the machine were modified to permit the use of Canadian materials. This machine is used for testing resistance to shock of various electrical equipment, such as switches, rheostats, junction boxes, lighting fixtures used by Navy and merchant ships. From the results obtained specifications for all electrical equipment for the purposes enumerated are being developed as required. Problems investigated in the electrical engineering section have included studies of gear for magnetic minesweeping. A rocking machine to stimulate the rolling of a boat has been constructed, and tests of various instruments have been made on this unit.

In the Division of Chemistry many problems of interest to the Navy have been investigated. Work on paints, rubber, low-alloy high-strength steels and aluminium alloys, and sea-water resistance of various coatings and inhibition of corrosion of various metals by chemicals may be mentioned. In the Division of Mechanical Engineering, likewise, the several laboratories are engaged on numerous problems for the Navy, notably in matters relating to engines and their lubrication, the design and test of boats of various types.

For the Army

For the Army and also for the other Services all kinds of supplies have had to be tested to determine whether they are acceptable according to required military standards. Apparatus has been developed and constructed for work in ballistics on an increasing scale. Measuring equipment for ammunition proof and gun proof has been developed and is in continuous service at proving grounds. Problems on the direction of gun-fire have been attacked with success. Numerous tests have also been made on the armouring properties of various materials and work is in progress on the improvement of anti-aircraft projectiles.

An important war service was rendered in 1939 by promoting the development in Canada of optical glass manufacture for the production of precise optical parts for military equipment. The project is now being carried forward in production by a Government-owned company. Equipment was installed and a staff assembled in the National Research Laboratories for the inspection of gauges used in the production of guns, shells, fuses, bombs and other mechanical items which are now being made in mass production.

Another important activity of the Army which is built on science is chemical warfare. From a small co-operative effort between the National Research Council and the Army, this activity has developed rapidly and is now a highly co-ordinated project operating as a directorate of the Department of National Defence, but under a director-general who is a civilian scientific worker on the staff of the National Research Council. Of the active personnel about one half are civilian men of science and the rest are Service men.

Indicators for war gases and chemicals for other war services have been synthesized and studied. The rubber laboratory has investigated, for production purposes or improvements, products used by almost every branch of the Armed Forces, including surgeons' gloves, ground sheets, gas-mask components, artillery and tank parts, crash and steel helmets. In addition, the laboratory has made numerous acceptance tests on contract deliveries. Recently much attention has been given to rubber conservation problems and to the study of synthetic rubber processes. Commercial production of fuse-powder charcoal was carried on until recently by the National Research Council; manufacturing has now been turned over to a commercial concern. Research on the fundamental problems involved in the operation is being continued by the Council.

Activities in the textile laboratory have been largely in connexion with acceptance test work and specifications. Special problems included an investigation of methods to reduce weathering of canvas duck, a study of thermal transmission of blankets, colour analyses of certain types of textile products and work on respirator pads. Materials tested included felt, silk gauze, silk thread, braid, vulcanized cloth, box cloth and various types of uniform materials. A large amount of work is being carried out on the development of suitable types of anti-gas impermeable-type fabrics and on the maintenance of suitable standards of quality in material of the type which is being manufactured in Canada. Other studies include work on the water-proofing, mildew-proofing and flame-proofing of cotton textiles.

Inspections have been made and advice given as to the suitability of a variety of leathers for different military purposes. Examination has been made of numerous dressings and waterproofing compounds for leathers. Tensile-strength tests on leathers, and wear-resistance tests, chiefly on composition-sole materials, were carried out for the Department of National Defence. Used militia boots were examined for the cause of cracking in the vamps. Research on the deterioration of shoe uppers has been continued.

Component parts of certain anti-aircraft protection devices were constructed. Transparent sheet resins for military purposes have been tested against specifications; vulcanized fibre identification disks and other objects have been examined, and general consideration has been given to the substitution of plastics for metals in a number of articles and parts related to war materials.

Preservative coatings for use on military vehicles and other equipment for war purposes have been developed. A surprising variety of finishes is required in this field and many of the materials are comparatively new to Canadian industry. The laboratories have co-operated with Government authorities and manufacturers to facilitate the supply of these highly specialized coatings. Gas-detector paints, luminous paints, finishes for rifle barrels, camouflage paints and other special paints have been developed.

Mention should be made of the establishment of an explosives laboratory to carry out testing required under the Explosives Act and to conduct research on explosives and related compounds. This laboratory is under the joint administration of the National Research Council and the Department of Mines and Resources. An Associate Committee on Explosives has been established to co-ordinate and direct all work in this field.

For the Air Force

Establishment of the new aeronautical laboratories just outside Ottawa has provided improved facilities for research on the multitude of problems arising from modern trends in aviation. Closest co-operation is maintained between the Royal Canadian Air Force and the Council's laboratories through the Associate Committee on Aeronautical Research, the chairman of which is the Air Member for Aeronautical Engineering, R.C.A.F. Much of the work in progress relates to problems that have been suggested by Air Force authorities in Canada, the United Kingdom or the United States.

Horizontal and vertical wind tunnels are in use. In the engine laboratory dynamometer rooms are provided for the testing of aircraft engines, while in the gasoline and oil laboratory complete equipment is provided for physical and chemical testing of aviation fuels and lubricants. A structures laboratory provides for the fabrication of prototypes of aircraft and for the test of component parts.

Experimental work required in connexion with scientific problems under investigation in the National Research Laboratories is often carried out co-operatively with the Royal Canadian Air Force Test and Development Establishment, which is really a full-scale experimental flying station.

During the year the Radio Section continued to work on the development of secret radio locator equipment with considerable success. There are already in the hands of the Services numerous different equipments which have been developed in the National Research Laboratories. Some of these have already been used successfully against the enemy.

Medical Research

In the field of medical research an active committee of the Council has made great progress. The original purpose of this committee was to co-ordinate medical research in Canadian institutions and to assist in its development. The activities of this committee are now wholly directed to war problems. The work has grown to such an extent that several new sub-committees have had to be established to deal with questions of shock and blood substitutes, wound infection and surgical problems. Regional committees have been appointed to facilitate the work. Liaison with Great Britain and the United States has enabled Canada to co-operate effectively with them in the promotion of medical investigations arising from war problems. More recently, Australia and New Zealand have been included in the interchange of reports.

In the field of medical research as applied specifically to the Services, three associate committees are in operation dealing respectively with aviation, naval and army medical research problems.

The first of these associate committees, on aviation medical research, was formed early in 1940 and has carried out a most impressive programme of work, especially in the fields of high-altitude flying and protective clothing. The work of the Naval Committee has been directed to the improvement of innumerable factors effecting the efficiency of personnel on boats, and the Army deals with similar problems of Service men who have to operate in tanks and work under the innumerable special Service conditions attendant on modern warfare.

Research activities under these committees have been carried on at most of the universities of Canada and at the National Research Council, the Ontario Research Foundation and the clinical investigation units and other establishments of the Services. The close collaboration existing between the civilian and Service groups of workers and the help and advice so freely offered by industrial concerns have greatly accelerated the solution of a number of important problems.

For War Industries

The Division of Applied Biology has rendered valuable assistance in the fitting of temporary refrigerators on merchant vessels. The successful transport of perishable foodstuffs demands refrigerated shipping space or the conversion of the material to a less perishable form that can be carried in ordinary stowage. This problem is most acute for bacon, which goes forward in large volume. The shortage of refrigerated space has also affected other perishable commodities. Considerable work has been done on the treatment of shell eggs to avoid deterioration during shipment at ordinary temperatures. All export eggs, however, are now shipped in powder form, and the work of this group of investigators is therefore directed towards the development of methods for assessing quality and developing drying processes capable of producing a dried egg material of high quality.

Dehydration of meat, chiefly pork and cured ham has been studied, and an acceptable quality of product has been obtained. Closely related to food studies on products for shipments overseas is the development of containers in which a substitute for tin plate has been used. Packages based primarily on fibre and wax combinations have been found useful. Dehydrated products require packaging in waterproof materials.

The need for magnesium led to intensive research and resulted in the development of a process well suited to Canadian conditions of production. A plant of ten tons capacity per day, built by the Department of Munitions and Supply to use this process, is in operation, while plants totalling about a hundred tons per day capacity are being built in several centres in the United States.

The shortage of natural rubber, which is so important for military purposes in this age of mechanization, has stimulated research on the possibility of producing rubber from plants that can be grown on the American continent. Synthetic rubbers of various types are being developed and tested, and plants are being established for the production of the more useful types.

SCIENTIFIC PROGRESS SINCE 1840

In a lecture, "A Century of Progress: Men, Manners, Inventions", given before the Lancastrian Frankland Society on January 15, Dr. E. F. Armstrong drew a stimulating comparison between the conditions of Edward Frankland's early years in Lancaster and to-day. Referring to the encouragement which Frankland received from the Johnsons in Lancaster, who sent him to Playfair in 1845, Dr. Armstrong remarked that the energy to get on in spite of the most adverse and discouraging circumstances was characteristic of the 1840's. A deep interest in Nature and in intellectual matters was also widespread in the north of England during the Victorian period and led to the formation of many local societies, ranging from the mutual improvement societies of the chapels to the mechanics institutes and literary and scientific societies of the small towns and the philosophical societies of the large cities. These societies, which besides spreading knowledge gave inspiration to the younger members, persisted until improved communications, a multitude of technical journals and the spread of technical colleges drove most of them out of existence, although even now technical societies with local sections have a most important function.

Frankland apparently took up science as a career through his parents instilling a spirit of inquiry and the desire to find out things for oneself. Commenting on the fact that the period 1840–70 saw the birth and entry into the sciences of a great many men from very diverse walks of life, whose achievements have laid the foundations on which we are building to-day, Dr. Armstrong directed attention to the early life of austerity and struggle which developed their powers. Among these were James Dewar, Horace and Adrian Brown, Charles Lapworth, Richard Threlfall, Alfred Yarrow, Bates of Amazon fame, C. F. Cross, James Alfred Ewing, and H. B. Baker.

The chief characteristics of the last hundred years, Dr. Armstrong suggested, are the inventions and discoveries which have so markedly affected the material progress of the world that they may well be regarded as the seven modern wonders of the world, superseding the seven architectural wonders of the past. The first of these is pure water supply, in the provision of which Frankland himself played a large part. As a scientific member of the Royal Commission appointed in 1867, he found that the oxidation and destruction of the organic matters present in town drainage took place with extreme slowness, contrary to the previous belief. He found, on the other hand, that slow percolation through porous soil effected this oxidation and destruction with great rapidity. Frankland also improved the old and devised new methods of water analysis, and throughout his life took special interest in the water supply of London, while his son, Percy Frankland, took up the study of the biological aspects of the problem. Continuing this work, Sir A. C. Houston, the pioneer of systematic chlorination treatment on a large scale, was also responsible for the scientific application of bacteriology for improving and safeguarding the purity of water. Dr. Armstrong referred here to his previous suggestion that a tablet commemorating these achievements of Frankland should be placed on the great new dam across Hawes-water.

Second of the modern seven wonders, both in point of time and importance to pure water, must be ranked electricity, which from its gradual development, starting with its use in signalling by Cook and Wheatstone, with no encouragement by the State, has now become a major industry touching almost every home. The third wonder was the spinning of viscose or Rayon from wood, with the consequent revolution in women's dress. Even now we are only at the beginning, the newest of all these fibres being Nylon, a wholly synthetic fibre, built up as it were from carbon, water and air, with properties as good or better than those of silk spun by the silkworm.

The fourth and fifth wonders, the internal combustion engine and hydrocarbon oil, are so interdependent that they may well be considered together. Giving us speedy transport on land, on sea and in the air, they have made the world one community. Speedy travel has had great political repercussions; and no individual, community or nation can withdraw at will to a quiet corner to follow its own inclinations. The development of the internal combustion engine was based on progress in design correlated with progress in metallurgy, while the oil industry was providing raw materials for many diverse chemical operations and was destined to displace coal tar and coal as the world's most important basic raw material for chemical synthesis —probably with further effects on our own post-war economy following on those already involved in the displacement or disappearance of cheap coal.

Next among modern wonders came the radio, which is enabling all to lead a fuller and broader life. Its cultural and scientific significance is not yet fully appreciated, and despite its importance in war the future applications may be astounding. The last wonder, Dr. Armstrong said, was the plastics, of which the man in the street is as yet only dimly conscious, although they are destined to make life easier for us all, to provide objects of utility, and should also make artistic design and beauty available at prices diminishing rather than increasing. Finally, Dr. Armstrong pointed out that the satisfactory solution of the problems of society into which science enters will be based on moral influence, and our effectiveness will depend on the devotion, wisdom and goodwill which we bring to our task.

A SPREAD-SCALE RECORDER

In an article with this title (*Bell. Lab. Rec.*, 21, No. 3; November 1942) O. D. Engstrom points out that the transmission tolerances of telephone circuits have become more severe, requiring a corresponding improvement in measuring technique and equipment. When a telephone circuit had only a few amplifiers or other circuit units, each could be permitted a larger share of the total permissible distortion, and errors in measurement of 0·25 db. meant very little. With the present transmission systems requiring many more circuit units than the earlier systems, this situation has changed. More accurate and faster operating testing equipment has been required, and a recording transmission-measuring set was developed that covers the voice-frequency spectrum in a few minutes. As originally used, the chart of this recorder could be read to about 0·2 db., but for many present-day measurements this is not adequate, and a new 'spread-scale' recorder has been developed that can be read to 0·02 db.

For a transmission measurement, an adjustable-frequency oscillator is provided with a small synchronous motor that changes the output frequency continuously over the range from 200 to 3,500 cycles for each test. An equalizer and adjustable attenuator in the output of the oscillator maintain the output power constant at the desired level for the test. At the output of the circuit being measured is an I–U amplifier-rectifier that converts the received A.C. into D.C. for operating the recorder. A 500 cycle selective detector is employed to mark the chart at a point corresponding to a test frequency of 500 cycles, and this mark is used in placing the frequency ordinates on the chart. A biasing circuit was added as one of the changes required to produce the spread-scale characteristic.

To secure the added precision needed for a chart that is to be read to 0·02 db., certain other changes were made, including principally an increased voltage stability of the power supplies and an increased stability of the oscillator output and of the detector gain as the frequency varied over the test range. Steps taken to improve the circuit in these respects include the provision of a regulated plate-battery power supply for both the oscillator and the detector, storage battery for filament supply, the selection of quiet tubes, and special regulation for the oscillator output characteristics.

The circuit is calibrated by applying an input of 10 db. below 1 milliwatt to the amplifier-rectifier, and then adjusting the resistance in the circuit of the biasing battery until a mid-scale deflexion is obtained. When making a measurement of the transmission characteristic of a piece of equipment, it is then necessary to adjust the oscillator output so that the output of the equipment under test is 10 db. below 1 milliwatt at roughly the frequency of the mean attenuation. The dial of the oscillator is then set below the edge of the desired band, and the oscillator and recorder are both started. The article describes and illustrates the recorder and its performance characteristics in detail.

FORTHCOMING EVENTS

(Meetings marked with an asterisk are open to the public)

Saturday, February 27

Malacological Society (at the Linnean Society, Burlington House, Piccadilly, London, W.1), at 2.30 p.m.—Annual General Meeting and Commemoration of the 50th Anniversary of the Society's Foundation.

Light Railway Transport League (at Fred Tallant Hall, Room J, Drummond Street, London, N.W.1), at 3 p.m.—Dr. Hugh Nicol: "A Scientist Looks at Transport".*

Monday, March 1

Farmers' Club (at the Royal Empire Society, Craven Street, Strand, London, W.C.2), at 2.30 p.m.—Sir William Prince-Smith, Bart.: "An Industrialist's Views on Agriculture and its Future".

Tuesday, March 2

Manchester Literary and Philosophical Society (in the Geographical Department, The University, Manchester), at 5 p.m.—Prof. J. Kenner, F.R.S.: "Historical Method in Teaching Science".

Institute of Welding (at the Institution of Mechanical Engineers, Storey's Gate, St. James's Park, London, S.W.1), at 6 p.m.—A series of Papers on "Developments in Arc Welding Technique".

Wednesday, March 3

Royal Society of Arts (at John Adam Street, Adelphi, London W.C.2), at 1.45 p.m.—Dr. J. D. Robertson: "Calcium Metabolism in Health and Disease".

Physical Society (Colour Group) (in the Lecture Theatre of the Science Museum, Exhibition Road, London, S.W.7), at 2.30 p.m.—Third Annual General Meeting. At 3 p.m.—Mr. J. Guild: "The Significance and Limitations of the C.I.E. Standard Observer Tables"

Institute of Metals (at the Institution of Mechanical Engineers Storey's Gate, St. James's Park, London, S.W.1), at 3 p.m.—35th Annual General Meeting. Dr. Harold Moore: "Co-operative Research in the Metal Industries".

Institution of Mechanical Engineers (Joint Meeting with the Iron and Steel Institute and the Institute of Metals) (at Storey's Gate, St. James's Park, London, S.W.1), at 5.30 p.m.—Dr S. W. Smith: "The Life and Work of Sir William Chandler Roberts-Austen".

Thursday, March 4

Institution of Electrical Engineers (at Savoy Place, Victoria Embankment, London, W.C.2), at 5 p.m.—Sound Films of Honorary Members and Faraday Medallists—Sir J. J. Thomson, O.M., F.R.S. Lord Rutherford, O.M., F.R.S.

Friday, March 5

Royal Society of Arts (India and Burma Section) (at John Adam Street, Adelphi, London, W.C.2), at 1.45 p.m.—Sir Malcolm Darling: "The Indian Village and Democracy".

Royal Institution (at 21 Albemarle Street, London, W.1), at 5 p.m.—Sir John Russell, F.R.S.: "Restarting of Agriculture in Devastated Europe".

Saturday, March 6

Geologists' Association (at the Geological Society of London, Burlington House, Piccadilly, London, W.1), at 2.30 p.m.—Annual General Meeting. Prof. H. H. Read, F.R.S.: "Meditations on Granite" (Presidential Address).

Friday, March 5—Sunday, March 7

Institute of Industrial Administration (at the Waldorf Hotel Aldwych, London, W.C.2). Conference on "Training for Industrial Management".*

Friday, March 5

4.30 p.m.—Registration of Members.

Saturday, March 6

10 a.m.—Management and the Nation.
11.15 a.m.—Address by His Grace the Lord Archbishop of Canterbury.
12.30 p.m.—Management and Industry.
3 p.m.—External Training for Industry.
5.30 p.m.—Internal Training in Industry.

Sunday, March 7

10 a.m.—Management and the Board Room.
11.30 a.m.—Review of Conference.

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Lecturer-Instructor in Engineering Workshop Technology and Practice in the Bolton Municipal Technical College—The Director of Education, Education Offices, Nelson Square, Bolton (March 5).

Master to teach Mathematics and Science at the Bingley Technical School—The Divisional Educational Officer, Education Offices, Bingley, Yorks. (March 7).

Lecturer in Mechanical Engineering in the Oxford Schools of Technology, Art and Commerce—The Chief Education Officer, City Education Office, 77 George Street, Oxford (March 9).

Lecturer of Textile Testing in the School of Textiles—The Principal, College of Technology and Commerce, Leicester (March 13).

Chair of Chemistry in the University College of North Wales—The Bursar and Acting Registrar, University College of North Wales, Bangor (April 3).

Assistant Field Officer (either sex) for Crop Investigations of Mineral Deficiencies—The Secretary, Research Station, East Malling Kent.

Assistant (woman) for the Strawberry Nuclear Stocks Scheme—The Secretary, Research Station, East Malling, Kent.

Technical Assistant (male or female) in the Department of Economics—The Secretary, South-Eastern Agricultural College, Wye, Kent.

Assistant Engineers for operation and maintenance of hydro-electric Public Supply Company, Nigerian Plateau—The Ministry of Labour and National Service, Central (Technical and Scientific) Register, Section D.553X, Alexandra House, Kingsway, London, W.C.2.

Lecturer in Mechanical Engineering—The Secretary, Woolwich Polytechnic, Woolwich, London, S.E.18.

INDUSTRY AND EDUCATION

NO one would doubt, even in normal times, that the relations between industry and education are of fundamental importance to the planning of our life as a nation. The War has heightened that importance. It has "already brought with it changes in the structure and working of industry, above all on the human side, much further-reaching than those which developed during the last war". That quotation occurs in a statement on "Industry and Education"* which has been issued as a result of a conference between educationists and industrialists held towards the end of last year, under the auspices of Nuffield College, Oxford.

We commend the statement to the careful consideration of our readers. It does not, as its authors are at pains to point out, pretend to anything which is to be regarded as a scheme—final, rounded and authoritative. It embodies suggestions, and the aim of submitting those suggestions has been to provoke discussion and "to test the degree of agreement which exists among our colleagues in industry, in the universities and technical colleges, and in other walks of life".

The statement opens by laying down the fact that, after the War, our hope for steady and speedy advancement in wealth and welfare depends upon the extent to which we are able "to produce efficiently and cheaply a wide range of goods for consumption overseas as well as at home". In other words, all plans for advancing our standards of living "must depend, in the last resort, on the efficiency of British production and on the ability of British industry to sell goods in the world market".

How is that to be done ? The call for "cheap production" is very often linked with an emphasis on the need for "cheap labour". Such a solution is dismissed at once. Any attempt to solve the problem on the basis of low-wage competition is bound, says the statement, to end in failure. We must, instead, look to the quality of our labour and to the "attitude towards production of individuals who comprise the labour force", for they are the vital factors in raising productivity to a satisfactory level. Labour which is badly paid and discontented is never really cheap.

To secure quality of labour a planned scheme of education is essential, and it is here that the statement is crystal clear in its view that, so far as those who leave school at the statutory age are concerned, industry does not ask that they shall have received any specific vocational preparation for the occupations they are about to enter. "Industry itself can best undertake the specific training of such entrants, or collaborate with educational agencies in providing it after they have left school." What is needed in the case of these young people, including those in junior technical and secondary schools, is a broadly non-vocational course. That does not mean to say that the curriculum in all these schools should follow precisely the same lines. It means that while the technical school can provide a curriculum "centring on basic mathematics and science but also paying due attention to English and to social subjects", in a senior or secondary school "the teaching of cultural subjects will be combined with an attempt to give every pupil a sufficient grounding in elementary mathematics and in the foundations of science". The intention, for all these pupils, is to secure the speaking and writing of good and exact English and "a clear understanding of the essential character and institutions of the society" in which they will later have to play their part. Nor are these things to be regarded as separate 'subjects'. They are to be regarded as integral to the whole course and should therefore permeate the teaching of all subjects.

---

* Oxford University Press, 1943. 1s. net.

Even if that were accomplished, however, the statement recognizes there will still be those who may have no prospect of rising from the lower ranks of their vocations. These will include repetition workers and, although it is believed that "industry will need not less but more intelligence and adaptability as mechanisation makes further advances", it is vital to prevent that sense of thwartedness which is always a possible danger. To that end, employers should be prepared to grant these workers a dual road to self-development by broadening the avenues of advancement and by release for study not necessarily connected with their work. Who will not agree with the view that "It is no mean part of industry's responsibility to those whom it employs to ensure that both these ways of human progress shall be made broad and easy of access to all-comers" ?

But while those who enter industry after the statutory school-leaving age constitute the majority, there are two other groups of entrants to industry : those who remain at secondary or technical schools after the statutory leaving age but do not proceed to full-time courses at a university or technical college, and those who enter industry either directly after a full-time university or higher technical course, or after a further period of study or research following such a course.

In the case of those who enter from secondary schools a reform appears immediately necessary. It is that the course they follow should be complete in itself. What industry sees here is that at present such courses are too often devised primarily as a preparation for university courses which, in fact, are not likely to be pursued by the majority. But to attain that end "it is necessary to release the schools from thraldom to an examination system conceived too much under university influence, or rather from a standpoint which regards the school primarily as a place of preparation for university work". The technicalities are not argued, but we believe that the authors of the statement have put their fingers on a matter which is already receiving the attention of a very large number of educationists whose starting point has by no means been the same.

From these schools, again, industry asks for the broadest and deepest possible development of general intelligence and initiative, and a sound basis of general scientific and mathematical knowledge. It is just as contrary to the requirements of industry as it is to the balanced growth of the individual that there should be any premature specialization. The first essential is to make firm the foundations. When these pupils have entered industry there should be the widest possible opportunities for further education in all its phases.

The final group of entrants are those who come after full-time courses at a university or technical college. They are those who may be expected to be the main supply for the higher personnel of industry and for industrial research ; and it is in connexion with their case that the statement turns a critical eye upon university scholarship examinations. If premature specialization at school is bad, the present tendency for those scholarship examinations to be unduly specialized must be altered. The statement therefore strongly urges university authorities to insist on a firm grounding in mathematics and science rather than on a high standard of specialized knowledge. We agree. Specialization is essential in the higher ranges of knowledge, but it must rest upon a broad groundwork. There is little need to emphasize even the potential danger of a 'specialist' who lacks what is called a cultural background. The phrase savours sometimes of the cliché : but we know that, whatever else it may mean, it means the ability to appreciate the wide issues of industrial organization and policy, the place which industry occupies in the community and the processes of social as well as technological development. Without that ability specialization lacks also the "qualities of leadership, initiative and imagination".

We are all familiar with the need for closer contact between industry and the universities. The statement makes important suggestions in that direction. These include the use of the staffs of industrial research laboratories to give courses of lectures to university students, and the seconding of university teachers and research workers for periods of service with the research staffs attached to particular industries. Moreover, the movement to and fro between 'pure' and industrial research could be made a good deal easier. Adjustments would be necessary, of course. Salary structures and other conditions are different, but they could and should be arranged in order to secure the end in view.

The authors of the statement believe, as we believe, that industry has a right to a higher proportion of the best men from the universities. The claim, in our view, is soundly based. If national standards are to be improved, the need to harness scientific knowledge fully to the promotion of higher industrial productivity is imperative. We know the value of the work done in this connexion by the university appointments boards ; but we agree that it is not enough. For that reason we believe that the suggestion of carrying on and improving the work of the Central Register which the War has brought into being is a useful one. It would not replace or make unnecessary the closer contact between university teaching staffs and those who deal with recruitment of the higher personnel of industry ; but it would be an advance in the right direction.

So much for the universities. But anyone who knows the details of industrial personnel knows the tremendous contributions made by technical colleges.

It was to be expected, therefore, that the relationship between university and technical college should be raised in any document dealing with the flow of recruits to all parts of the industrial structure. Clearly a large expansion of technical education is indicated in the future, and the proposal that the higher forms of technical education should be concentrated in the universities was bound to be examined. We are glad to note that the statement strongly dissents from that proposal. The intention may be admirable, but we agree that it is quite impracticable to separate the higher from the less advanced forms of technical education, "or to bring within the existing universities the large numbers who need higher technical training of one sort or another". The statement, therefore, supports the idea which has sometimes been expressed as the development of universities and technical colleges as the "twin tops of the educational system". The statement does not use that phrase. Instead it uses the phrase "People's University", and suggests the "making of technical colleges and other institutions which suffer from a parallel isolation and incompleteness into the nuclei of a new type of people's colleges, equipped both to train students for a wide range of vocations and to play an active part in widening the sphere of adult education". That method, it is suggested, "offers by far the best hope of endowing higher technical education with that cultural quality in which it is now too often deficient, and of constituting it a school of personality and leadership as well as technical skill". We are by no means disposed to accept all the implications of that quotation, but we need not here indicate assumptions which seem to us to lack foundation. The main idea is that of the people's college, and with that we are in cordial agreement.

Let us note in conclusion a protest made quite early in the statement. It is against the bias of the educational system against entry into manual occupations. There can be no doubt that the move towards "directing boys who are above the average intelligence into non-manual work" exists, and we agree with the protest "except where the non-manual occupations are such as to call for a high degree of intelligence". That bias against manual occupations has not, however, appeared without some reason. We recall having directed attention in these columns to at least one reason. It was so far back as November 12, 1927. What was said then bears repetition now:

> "This fault of shaping the bright boy to the black suit was regarded as belonging to parents and teachers rather than to employers. But are parents and teachers to receive all the blame? Is it not generally true that difference of status exists? Is it not generally true that in times of bad trade it is the production side which suffers while the administrative side enjoys something very like permanence? Can the employer help to avoid this—a very real threat to the future and welfare of industry?"

With that in mind we direct special attention to the final passage of the statement we are noting. It is headed "The Need for Hope". It underlines the passage we have just quoted when it says: "To most workmen and to many technicians the supreme discouragement to the development and display of the higher faculties is the fear of unemployment. . . . Not one of the suggestions we have put forward will bear its full fruit unless this inhibiting tenor can be exorcised." Industry must be forward-looking and assured that it "will not be made the sport either of defective financial arrangements or of official timidity in facing fundamental economic problems". Men live and work happily when they have hope, and because of that we need not amplify further the quotations we have selected. If their main suggestions go unheeded, the rest of the statement might just as well not have been written.

COLLOIDAL AND AMORPHOUS MATERIALS

Industrial Chemistry of Colloidal and Amorphous Materials

By Prof. Warren K. Lewis, Lombard Squires and Dr. Geoffrey Broughton. Pp. xii+540. (New York: The Macmillan Company, 1942.) 5.50 dollars.

IT is related that Prof. Nernst was wont to refer to the science of colloids as *die trübe Wissenschaft* (the cloudy science). The innuendo implied in this witty remark was not without some justification at one time, but that day is long past. So great have been the advances made during the last thirty or forty years in the study of sols and gels, interfacial properties and actions, and the structure and behaviour of large molecules or micelles—from 'macro' to 'mega'—that colloid science with its many applications now occupies a position of great and growing importance, and can offer to the student of Nature not only a very large body of quantitatively well established and well correlated phenomena, but also a corresponding body of scientific principles and reasoning.

The present book, a most admirable one and unique in many respects, comes from the Chemical Engineering Department of the famous Massachusetts Institute of Technology, the senior author, Warren K. Lewis, being the well-known professor in that Department, an honorary member of the Institution of Chemical Engineers (Great Britain), and long known throughout the world to students of chemistry as one of the authors of that famous pioneering work, "Principles of Chemical Engineering", first published in 1923. The other joint authors of the present book are former members of the Chemical Engineering Department of the Massachusetts Institute of Technology and now occupy important positions as chemical engineers in two of the greatest industrial concerns of the United States, namely, the E.I. du Pont de Nemours Company and the Eastman Kodak Company. No book intended to instil into the minds of chemistry students the fundamental underlying science and many of the essential facts and phenomena relating to the processes of many great industries could come before the public with better credentials.

As the authors explain in the preface, students starting the study of fields of applied chemistry such as the so-called heavy chemical industry possess in general an adequate background of training in inorganic, organic, analytical and physical chemistry. This is not true, however, of the great industrial field of colloidal and amorphous materials, and for two reasons. In the first place, the subject of physical chemistry is so broad that instruction to be thorough must be restricted in scope, with the result that it is not possible to deal adequately with the scientific facts and principles underlying the phenomena presented by colloid and 'amorphous' systems. In the second place, these phenomena are so complex that "many individuals prefer a purely empirical approach, but it is the conviction of the writers that it is best to submit each problem to a careful theoretical analysis, even though in the nature of the specific case this may be known to be inadequate. A major purpose, therefore, is the introduction of the student to such a method of attack".
